Chapter 0

Prelude

0.1 About this Book

The Aim of this Book

Mathematics knows two directions - analysis and algebra - and any mathematical discipline can be weighted how analytical resp. algebraical it is. Analysis is characterized by having a notion of convergence that allows to approximate solutions (and reach them in the limit). Algebra is characterized by having no notion convergence and hence allowing finite computations only. This book now is meant to be a thorough introduction into algebra.

So where does algebra draw its power from? Many structures can be seen by clever computations - like determinant theory or dimension in vector spaces. But a lot of insights are derived from the order the subset relation "$\subseteq$" establishes on the algebraic object - e.g. maximal ideals are one of the mostly used tools. More generally Zorn's lemma lies at the bottom of so many theorems. And at some points, when finite computations are not enough, algebra has to turn to topology. Analytical arguments (convergence and taking limits) are exceedingly rare, however. In this sense algebra is the more fundamental theory.

Likewise every textbook on mathematics is drawn between two pairs of extremes: (easy understandability versus great generality) and (completeness versus having a clear line of thought). Among these contrary poles we usually chose (generality over understandability) and (completeness over a clear red line). Nevertheless we try to reach understandability by being very precise and accurate and including many remarks and examples.

At last some personal philosophy: A perfect proof is like a perfect gem - unbreakably hard, spotlessly clear, flawlessly cut and beautifully displayed. In this book we are trying to collect such gemstones. And we are proud to claim, that we are honest about where a proof is due and present complete proofs of almost every claim contained herein.

Most textbooks on more advanced topics only present the stepping stones of how a proof works and do not bother to fill in the details. It is commonplace that some propositions are given in exercises only, completely devoid of any proof. While this might be sufficient to get the idea across, we want to raise a question here: How can the reader convince himself, that the proof truly works out, without filling in the details himself? This is why we chose to present *full* proves of *all* propositions and theorems, we do not hesitate to get our hands dirty. This makes this textbook *very* different from almost any other.

This Book is Written for

many different kinds of mathematicians: Primarily it is meant to be a source of reference for intermediate to advanced students, who have already had a first contact with algebra and now closely examine some topic for their seminars, lectures or own thesis. But because of its great generality and completeness it is also suited as an encyclopedia for professors who prepare their lectures and researchers, as a source of reference covering the established theory.

Frankly this book is not perfectly suited to be a monograph for novices to mathematics. So if you are one, we think you can greatly profit from this book, but you will probably have to consult additional monographs (at a more introductory level) to help you guide you through this text.

Prerequisites

We take for granted, that the reader is familiar with the basic notions of naive logic (statements, implication, proof by contradiction, usage of quantifiers, ...). We sketch some naive set theory (Cantor's notion of a set, functions, partially ordered sets, equivalence relations, Zorn's Lemma, ...) but a thorough introduction would have to start with mathematical logic. We will present a short introduction to classes and the NBG axioms, when it comes to category theory. Further we require some basic knowledge of integers (including proofs by induction) and how to express them in decimal numbers. We will sometimes use the field of real numbers, as they are most probably well-known to the reader, but they are not required to understand this text. Aside from these prerequisites we will start from scratch.

Topics Covered

We start by introducing groups and rings, immediately specializing on rings. Of general ring theory we will introduce the basic notions only, e.g. the isomorphism theorems. Then we will turn our attention to commutative rings, which will be the first major topic of this book: We closely study maximal ideals, prime ideals, intersections of such (radical ideals) and the relations to localization. Further we will study rings with chain conditions (noetherian and artinian rings) including the Lasker-Noether theorem. This will lead to standard topics like the fundamental theorem of arithmetic. And we conclude commutative ring theory by studying discrete valuation rings, Dedekind domains and Hilbert rings.

Then we will turn our attention to modules, including rank, dimension and length. We will see that modules are a natural and powerful generalization of ideals and large parts of ring theory generalizes to this setting, e.g. localization and primary decomposition. Module theory naturally leads to linear algebra, i.e. the theory of matrix representations of a homomorphism of modules. Applying the structure theorems of modules (the invariant factor theorem to be precise) we will treat canonical form theory (e.g. rational canonic form and Jordan normal form). Our treatment of the invariant factor theorem is one of the flagships of this text. This part is concluded by presenting a thorough introduction to what is called multi-linear algebra. We will study dual pairings and tensor products of modules (and algebras) over a commutative base ring.

Vector spaces over the reals or complex numbers can be handles even in the case of infinite dimension. Hence there is a natural generalisation of linear algebra over these fields, that is called functional analysis. We will settle with the bounded case however - undbounded operators (that are required in quantum mechanics) would require measure theory and integration theory and this would call for a textbook of its own. So we only aim for the spectral theorem of bounded operators.

Next we will study polynomials from top down: That is we introduce general polynomial rings (also known as group algebras) and graded algebras. Only then we will regard the more classical problems of polynomials in one variable and their solvability. Finally we will regard polynomials in several variables again. Using Gröbner bases it is possible to solve abstract algebraic questions by purely computational means.

This will set the stage for our treatment of ring extensions: We will introduce the concept of integral ring extensions, transcendence bases and the Noeterian normalisation theorem. Another flagship of this text is the treatment of the Krull dimension of a ring. Although we stay purely algebraic we gain our inspiration from algebraic geometry here and include some remarks to enlighten the relation between these fields. Afterwards we turn our attention to systems of parameters, Galois theory and the Hilbert-Samuel polynomial, which provides another way of proving Krull's height theorem.

Then we will return to group theory: Most textbooks begin with this topic, but we chose not to. Even though group theory seems to be elementary and fundamental this is not quite true. In fact it heavily relies on arguments like divisibility and prime decomposition of integers, topics that are native to ring theory. And commutative groups are best treated from the point of view of module theory. Never the less you might as well skip the previous sections and start with group theory right away. We will present the standard topics: The isomorphism theorems, group actions (including the formula of Burnside), the theorems of Sylow and lastly the p-q-theorem. However we are aiming directly for the representation theory of finite groups.

Thus we have gathered a whole bunch of separate theories - and it is time for a second structurization (the first structurization being algebra itself). We will introduce the notions of categories, functors, equivalence of categories, (co-)products and so on. Categories are merely a manner of speaking - nothing that can be done with category theory could not have been achieved without. Yet the language of categories presents a unifying concept for all the different branches of mathematics, extending far beyond algebra. So we will first recollect which part of the theory we have established is what in the categorical setting. The categorial language is the right setting to treat chain complexes, especially exact sequences of modules. Finally we will present the basics of abelian categories as a unifying concept of all those separate theories.

Topics not Covered

There are many instances where, dropping a finiteness condition, one has to introduce some topology in order to pursue the theory further. Examples are: Linear algebra on infinite dimensional vector-spaces, representation theory of infinite groups and Galois theory of infinite field extensions. Another natural extension would be to introduce the Zariski topology on the spectrum of a ring, which would lead to the theory of schemes directly. Yet the scope of this text is purely algebraic and hence we will usually stop at the point where topology sets in (but give hints for further readings).

The Two Parts

Mathematics has a peculiarity to it: There are problems (and answers) that are easy to understand but hard to prove. The most famous example is Fermat's Last Theorem - the statement (for any $n \geq 3$ there are no non-trivial integers $(a, b, c) \in \mathbb{Z}^3$ that satisfy the equation $a^n + b^n = c^n$) can be understood by anyone. Yet the proof is *extremely* hard to provide. Of course this theorem has no value of its own (it is the proof that contains deep insights into the structure of mathematics), but this is no general rule:

E.g. the theorem of Wedderburn (every finite skew-field is a field) is easy and useful, but its proof requires the more advanced method of cyclotomic polynomials. Just a little more advanced: In a noetherian ring R any non-empty set $\mathcal{P} \neq \emptyset$ of prime ideals $\mathcal{P} \subseteq \operatorname{Spec}(R)$ contains both a maximal element $\mathfrak{p}^*$ and a minimal element $\mathfrak{p}_* \in \mathcal{P}$. The proof of the existence of $\mathfrak{p}_*$ requires Krull's height theorem, which is the capstone of dimension theory in commutative rings.
Thus we have chosen an unusual approach: We have separated the truth (i.e. definitions, examples and theorems) from their proofs. This enables us to present the truth in a stringent way, that allows the reader to get a feel for the mathematical objects displayed. Most of the proofs could have been given right away, but in several cases the proof of a statement can only be done after we have developed the theory further. Thus the sequel of theorems may (and will) be different from the order in which they are proved. Hence the two parts.
The easiest way to deal with this is the following: As you probably read the pdf of this text anyway, just open up two copies - one for the theorems and one for the proofs. Then you can easily switch between back and forth from the claim and its proof.

On Names

Many properties are named after famous mathematicians, we speak of noetherian rings and the Krull-dimension. When it comes to naming, we use the following conventions: (1) If the name of a mathematician is used in the name of a concept (a noun), we use a capital letter. We speak of the lemma of Gauss or the Krull-dimension of a ring. (2) If the name of a mathematician is used descriptively (in an adjective or adverb), we use a small letter. Rings are called artinian, or noetherian and $\mathbb{Z}[i]$ are the gaussian integrers. This is *not* an expression of disrespect, quite the contrary. But we feel, that the text gets more pleasant to read, in doing so.

Our best Advice

It is a well-known fact, that some proofs are just computational and only contain little (or even no) insight into the structure of mathematics. Others are brilliant, outstanding insights that are of no lesser importance than the theorem itself. Thus we have already included remarks of how the proof works in the first part of this book. And our best advice is to read a section entirely to get a feel for the objects involved - only then have a look at the proofs that have been recommended. Ignore the other proofs, unless you have to know about them, for some reason. At several occasions this text contains the symbols ($\diamondsuit$) and ($\blacksquare$) . These are meant to guide the reader in the following ways:

($\diamondsuit$) As we have assorted the topics covered thematically (paying little attention to the sequel of proofs) it might happen that a certain example or theorem is far beyond the scope of the theory presented so far. In this case the reader is asked to read over it lightly (or even skip it entirely) and return to it later (after he has gained some more experience).

($\blacksquare$) On some very rare occasions we will append a theorem without giving a proof (if the proof is beyond the scope of this text). Such an instance will be marked by the *black box* symbol. In this case we will always give a complete reference of the most readable proof the author is aware of. And this symbol will be hereditary, that is once we use a theorem that has not been proved any other proof relying on the unproved statement will also be branded by the black box symbol.

0.2 Open Publication License

I. Copyright

The copyright to each Open Publication is owned by its author(s) or designee.

II. Scope of License

The following license terms apply to all Open Publication works, unless otherwise explicitly stated in the document. Mere aggregation of Open Publication works or a portion of an Open Publication work with other works or programs on the same media shall not cause this license to apply to those other works. The aggregate work shall contain a notice specifying the inclusion of the Open Publication material and appropriate copyright notice.

Severability: If any part of this license is found to be unenforceable in any jurisdiction, the remaining portions of the license remain in force.

No Warranty: Open Publication works are licensed and provided "as is" without warranty of any kind, express or implied, including, but not limited to, the implied warranties of merchantability and fitness for a particular purpose or a warranty of non-infringement.

III. Requirements on both unmodified and modified Versions

Any publication in standard (paper) or any other (e.g. electronic) form shall require the citation of the original publisher and author. The publisher and author's names shall appear on all outer surfaces of the book. On all outer surfaces of the book the original publisher's name shall be as large as the title of the work and cited as possessive with respect to the title.

IV. Requirements on Modified Works

All modified versions of documents covered by this license, including translations, anthologies, compilations and partial documents, must meet the following requirements:

- The modified version must be labeled as such.
- The person making the modifications must be identified and the modifications dated.
- Acknowledgement of the original author and publisher if applicable must be retained according to normal academic citation practices. The location of the original unmodified document must be identified.
- The original author's (or authors') name(s) may not be used to assert or imply endorsement of the resulting document without the original author's (or authors') permission.

V. Good-Practice Recommendations

In addition to the requirements of this license, it is requested from and strongly recommended of re-distributors that:

- If you are distributing Open Publication works on hard-copy or CD-ROM, you provide e-mail notification to the authors of your intent to redistribute at least thirty days before your manuscript or media freeze, to give the authors time to provide updated documents. This notification should describe modifications, if any, made to the document.
- All substantive modifications (including deletions) be either clearly marked up in the document or else described in an attachment to the document. Finally, while it is not mandatory under this license, it is considered good form to offer a free copy of any hard-copy and CD-ROM expression of an Open Publication-licensed work to its author(s).

VI. License Options

Distribution and derivative of the work for commercial purposes is prohibited, unless prior permission is obtained from the copyright holder in written form. The work may be distributed without prior permission from the copyright holder, for purely educational purposes, that are completely free of charge, provided the Good-Practice Recommendations are fulfilled.

0.3 Notation and Symbols

Preliminaries

We now wish to include a set of the frequently used symbols, conventions and notations. We will elaborate on most of the set-theoretic constructions and facts summarized here, in section 0.4.

- First of all we employ the nice convention (introduced by Halmos) to write *iff* as an abbreviation for *if and only if*. That is A iff B is just the same, as $A \iff B$.
- We denote the set of *natural numbers* by $\mathbb{N} := \{ 0, 1, 2, 3, \dots \}$. That is $\mathbb{N}$ are the positive integers including zero. And for any two integers $a, b \in \mathbb{Z}$ we denote the interval of integer numbers ranging from a to b by $a \dots b := \{ k \in \mathbb{Z} \mid a \leq k \leq b \}$.
- We will denote the set of *integers* by $\mathbb{Z} = \mathbb{N} \cup (-\mathbb{N})$, and the set of *rational numbers* by $\mathbb{Q}$. Whereas $\mathbb{Z}$ will be taken for granted, the rational numbers will be introduced as the quotient field $\mathbb{Q} = \{ a/b \mid a, b \in \mathbb{Z}, b \neq 0 \}$ of $\mathbb{Z}$ in (1.31) and in section 2.10.
- The *reals* will be denoted by $\mathbb{R}$ and we will present an example of how they can be defined (without proving their properties however). The *complex numbers* will be denoted by $\mathbb{C} = \{ a + ib \mid a, b \in \mathbb{R} \}$ and we will present several ways of constructing them.
- $(\diamondsuit)$ We will sometimes use the *Kronecker-Symbol* $\delta(a, b)$ (in the literature this is also denoted by $\delta_{a,b}$), which is defined to be 1 iff $a = b$ and 0 for any $a \neq b$, formally

$$\delta(a, b) \;=\; \delta_{a,b} \;:=\; \begin{cases} 1 \text{ if } a = b \\ 0 \text{ if } a \neq b \end{cases}$$

 In most cases a and $b \in \mathbb{Z}$ will be integers and 0, $1 \in \mathbb{Z}$ will be integers, too. But in general we are given some ring $(R, +, \cdot)$ and a, $b \in X$ will be elements of an arbitrary set X. Then the elements 0 and $1 \in R$ on the right hand side are taken to be the zero-element 0 and unit-element 1 of the base ring R used.
- We will write $A \subseteq X$ to indicate that A is a subset of X and $A \subset X$ will denote strict inclusion (i.e. $A \subseteq X$ and there is some $x \in X$ with $x \notin A$). For any set X we denote its **power set** (i.e. the set of all its subsets) by $\mathcal{P}(X) := \{ A \mid A \subseteq X \}$. And for a subset $A \subseteq X$ (and X is understood) we denote the **complement** of A in X by $\complement A := X \setminus A$.
- Listing several elements $x_1, \dots, x_n \in X$ of some set X, we do not require these x_i to be pairwise distinct (e.g. $x_1 = x_2$ might well happen). Yet if we only give explicit names x_i to the elements of some previously given subset $A = \{ x_1, \dots, x_n \} \subseteq X$ we already consider the x_i to be pairwise distinct (that is $x_i = x_j$ implies $i = j$). Note that if the x_i (not the set $\{ x_1, \dots, x_n \}$) have been given, then $\{ x_1, \dots, x_n \}$ may hence contain fewer than n elements!
- Given an arbitrary set of sets $\mathcal{A}$ we define the *grand union* $\bigcup \mathcal{A}$ and the *grand intersection* $\bigcap \mathcal{A}$ to be the set consisting of all elements a that are contained in one (resp. all) of the sets $A \in \mathcal{A}$

$$\bigcup \mathcal{A} \;:=\; \{ a \mid \exists\, A \in \mathcal{A} : a \in A \}$$

$$\bigcap \mathcal{A} \;:=\; \{\, a \mid \forall\, A \in \mathcal{A} : a \in A \,\}$$

Note that $\bigcap \mathcal{A}$ only is a well-defined set, if $\mathcal{A} \neq \emptyset$ is non-empty. A well-known special case of this is the following: Consider any two sets A and B and let $\mathcal{A} := \{\, A, B \,\}$. Then $A \cup B = \bigcup \mathcal{A}$ and $A \cap B = \bigcap \mathcal{A}$. This notion is just a generalization of the ordinary union and intersection to arbitrary collections $\mathcal{A}$ of sets.

- If X and Y are any sets then we will denote the set of all functions from X to Y by $\mathcal{F}(X,Y) = Y^X = \{\, f \mid f : X \to Y \,\}$. And for any such function $f : X \to Y : x \mapsto f(x)$ we will denote its **graph** (note that from the set-theoretical point of view f *is* its graph) by

$$\Gamma(f) \;:=\; \{\, (x, f(x)) \mid x \in X \,\} \;\subseteq\; X \times Y$$

- Once we have defined functions, it is easy to define arbitrary **cartesian products**. That is let $I \neq \emptyset$ be any non-empty set and for any $i \in I$ let X_i be another set. Denote the union of all the X_i by

$$X \;:=\; \bigcup_{i \in I} X_i \;=\; \{\, x \mid \exists\, i \in I : x \in X_i \,\}$$

Then the cartesian product of the X_i consists of all the functions $x : I \to X$ such that for any $i \in I$ we have $x_i := x(i) \in X_i$. Note that thereby it is customary to write (x_i) in place of x. Formally

$$\prod_{i \in I} X_i \;:=\; \{\, x : I \to X : i \mapsto x_i \;\mid\; \forall\, i \in I : x_i \in X_i \,\}$$

- If $I \neq \emptyset$ is any index set and $A_i \subseteq X$ is a non-empty subset of X (where $i \in I$) then the **axiom of choice** states that there is a function $a : I \to X$ such that for any $i \in I$ we get $a(i) \in A_i$. In other words the product of non-empty sets is non-empty again. It is a remarkable fact that this seemingly trivial property has far-flung consequences, the lemma of Zorn being the most remarkable one.

$$\prod_{i \in I} X_i \;\neq\; \emptyset \quad\Longleftrightarrow\quad \forall\; i \in I \;:\; X_i \neq \emptyset$$

- Let $X \neq \emptyset$ be a non-empty set, then a subset of the form $R \subseteq X \times X$ said to be a **relation** on X. And in this case it is customary to write xRy instead of $(x,y) \in R$. This notation will be used primarily for partial orders and equivalence relations (see below).

- The following concepts will be addressed in section 0.4 in greater detail. We just want to summarize the most important results for quick reference: Consider any non-empty set $X \neq \emptyset$ again. Then a relation $\sim$ on X is said to be an **equivalence relation** on X, iff it is *reflexive*, *symmetric* and *transitive*. Formally that is for any x, y and $z \in X$ we get

$$\begin{aligned} x = y &\quad\Longrightarrow\quad x \sim y \\ x \sim y &\quad\Longrightarrow\quad y \sim x \\ x \sim y,\; y \sim z &\quad\Longrightarrow\quad x \sim z \end{aligned}$$

And in this case we define the **equivalence class** $[x]$ of x to be the set of all $y \in X$ being equivalent to x, that is $[x] := \{ y \in X \mid x \sim y \}$. And the set of all equivalence classes is denoted by $X/\sim := \{ [x] \mid x \in X \}$. Example: If $f : X \to Y$ is any function then we obtain an equivalence relation $\sim$ on X by letting $x \sim y \iff f(x) = f(y)$. Then the equivalence class of $x \in X$ is just the fiber $[x] = f^{-1}(f(x))$.

- Consider a non-empty set $X \neq \emptyset$ once more. Then a family of subsets $\mathcal{P} \subseteq \mathcal{P}(X)$ is said to be a **partition** of X, iff for any $P, Q \in \mathcal{P}$ we obtain the statements

$$\begin{aligned} X &= \bigcup \mathcal{P} \\ P &\neq \emptyset \\ P \neq Q &\implies P \cap Q = \emptyset \end{aligned}$$

 Example: If $\sim$ is an equivalence relation on X, then $X/\sim$ is a partition of X. Conversely if $\mathcal{P}$ is a partition of X, then we obtain an equivalence relation $\sim$ on X by letting $x \sim y \iff \exists P \in \mathcal{P} :$ $x \in P$ and $y \in P$. Hence there is a one-to-one correspondence between the equivalence relations on X and the partitions of X given by $\sim \mapsto X/\sim$.

- Consider any non-empty set $I \neq \emptyset$, then a relation $\leq$ on I is said to be a **partial order** on I, iff it is *reflexive*, *transitive* and *anti-symmetric*. Formally that is for any i, j and $k \in I$ we get

$$\begin{aligned} i = j &\implies i \leq j \\ i \leq j,\ j \leq k &\implies i \leq k \\ i \leq j,\ j \leq i &\implies i = j \end{aligned}$$

 And $\leq$ is said to be a **total** or **linear order** iff for any i, $j \in I$ we also get $i \leq j$ or $j \leq i$ (that is any two elements contained in I can be compared). Example: For any set X the inclusion relation $\subseteq$ is a partial (but not linear) order on $\mathcal{P}(X)$. If now $\leq$ is a linear order on I, then we define the *minimum* and *maximum* of i, $j \in I$ to be

$$i \wedge j := \begin{cases} i \text{ if } i \leq j \\ j \text{ if } j \leq i \end{cases} \qquad i \vee j := \begin{cases} j \text{ if } i \leq j \\ i \text{ if } j \leq i \end{cases}$$

- Now consider a partial order $\leq$ on the set X and a subset $A \subseteq X$. Then we define the set A_* of **minimal** respectively the set A^* of **maximal** elements of A to be the following

$$\begin{aligned} A_* &:= \{ a_* \in A \mid \forall\, a \in A : a \leq a_* \implies a = a_* \} \\ A^* &:= \{ a^* \in A \mid \forall\, a \in A : a^* \leq a \implies a = a^* \} \end{aligned}$$

 And an element $a_* \in A_*$ is said to be a *minimal* element of A. Likewise $a^* \in A^*$ is said to be a *maximal* element of A. Note that in general it may happen that A has several minimal (or maximal) elements or even none at all (e.g. $\mathbb{N}_* = \{0\}$ and $\mathbb{N}^* = \emptyset$). For a linear order minimal (and maximal) elements are unique however.

- Finally $\leq$ is said to be a **well-ordering** on the set X, iff $\leq$ is a linear order on X such that any non-empty subset $A \subseteq X$ has a (already unique) minimal element. Formally that is

$$\forall \emptyset \neq A \subseteq X \ \exists a_* \in A \quad \text{such that} \quad \forall a \in A : a_* \leq a$$

- Let $X \neq \emptyset$ be a non-empty set, then the **cardinality** of X is defined to be the *class* of all sets that correspond bijectively to X. Formally that is

$$|X| \ := \ \{ Y \mid \exists \omega : X \to Y \text{ bijective} \}$$

Note that most textbooks on set theory define the cardinality to be a certain representative of our $|X|$ here. However the exact definition is of no importance to us, what matters is comparing cardinalities: We define the following relation $\leq$ between cardinals:

$$\begin{aligned} |X| \ \leq \ |Y| \quad &:\Longleftrightarrow \quad \exists \iota : X \to Y \text{ injective} \\ &\Longleftrightarrow \quad \exists \pi : Y \to X \text{ surjective} \\ |X| \ = \ |Y| \quad &:\Longleftrightarrow \quad \exists \omega : X \to Y \text{ bijective} \\ &\Longleftrightarrow \quad |X| \leq |Y| \ \text{ and } \ |Y| \leq |X| \end{aligned}$$

Note that the first equivalence can be proved (as a standard exercise) using equivalence relations and a choice function (axiom of choice). The second equivalence is a rather non-trivial statement called the equivalence theorem of Bernstein (0.32). However these equivalences grant that $\leq$ has the properties of a partial order, i.e. reflexivity, transitivity and anti-symmetry. In fact $\leq$ even acts as a total order, that is we either have $|X| \leq |Y|$ or $|X| \leq |X|$ or both.

- Suppose $x_1, x_2, \ldots, x_n$ are pairwise distinct elements. Then the set $X := \{ x_1, \ldots, x_n \}$ clearly has n elements. Using cardialities this would be expressed, as

$$| \{ x_1, \ldots, x_n \} | \ = \ |1 \ldots n|$$

In this case $1 \ldots n \longleftrightarrow X : i \mapsto x_i$ could be used as a bijection. Yet we also introduce less cumbersome notation - if $x_1, x_2, \ldots, x_n$ are pairwise distinct (that is $x_i = x_j \implies i = j$) we let

$$\# \{ x_1, \ldots, x_n \} \ := \ n$$

In particular $\#\emptyset = 0$. Hence for any finite set X we have defined the **number of elements** $\#X$. A set that is not finite is said to be infinite (see below). And in this case (if we don't care just how infinite X is, countable, uncountable or whatever) we write

$$\#X \ := \ \infty$$

- Thereby a set X is said to be **finite** iff there is some $n \in \mathbb{N}$ such that $X \longleftrightarrow (1 \ldots n)$, that is iff $\#X = n \in \mathbb{N}$. And we usually denote the set of all finite subsets of X by

$$\Omega(X) \ := \ \{ A \subseteq X \mid \#A < \infty \}$$

Likewise X is said to be **infinite**, iff $\mathbb{N}$ can be embedded into X, formally $\mathbb{N} \hookrightarrow X$ or in other words $|\mathbb{N}| \leq |X|$. Note that thereby we obtain a rather astounding equivalence of the statements

(a) X is infinite

(b) $|X| = |X \times X|$

(c) $|X| = |\Omega(X)|$

- If X and Y are finite, disjoint sets, then clearly $\#(X \cup Y) = (\#X) + (\#Y)$. Likewise for any finite sets X and Y we have $\#(X \times Y) = (\#X) \cdot (\#Y)$, $\#\mathcal{P}(X) = 2^{\#X}$ and $\#\mathcal{F}(X,Y) = (\#Y)^{\#X}$. We will use these properties to extend the ordinary arithmetic of natural numbers to the arithmetic of cardinal numbers, by defining

$$\begin{aligned} |X| + |Y| &:= |X \sqcup Y| \\ |X| \cdot |Y| &:= |X \times Y| \\ 2^{|X|} &:= |\mathcal{P}(X)| \\ |Y|^{|X|} &:= |\mathcal{F}(X,Y)| \end{aligned}$$

 for arbitrary sets X and Y. Note that $\sqcup$ refers to the *disjoint union* of X any Y, that is $X \sqcup Y := (\{1\} \times X) \cup (\{2\} \times Y)$. This is not necessary, if X and Y are disjoint to begin with, in this case we could have taken $X \cup Y$ right away. However in general we have to provide a way of separating X and Y and this nicely performed by $X \sqcup Y$. We will discuss cardinals in detail in section 0.5. It is a non-surprising but also non-trivial fact, that the power set of X is truly larger than X

$$|X| \;<\; |\mathcal{P}(X)|$$

- ($\diamondsuit$) We will introduce and use several different notions of substructures and isomorphy. In order to avoid eventual misconceptions, we emphasize the kinds of structures regarded by applying subscripts to the symbols $\leq$ and $\trianglelefteq$ of substructures and $\cong$ of isomorphy. E.g. we will write $R \leq_r S$ to indicate, that R is a sub-ring of S, $\mathfrak{a} \trianglelefteq_i R$ to indicate that $\mathfrak{a}$ is an ideal of R and $R \cong_r S$ to indicate that R and S are isomorphic as rings. Note that the latter is different from $R \cong_m S$ (R and S are isomorphic as modules). And this can well make sense, if $R \leq_r S$ is a sub-ring, then S can be regarded as an R-module, as well. We will use the same subscripts for generated algebraic substructures, i.e. $\langle \bullet \rangle_r$ for rings, $\langle \bullet \rangle_i$ for ideals and $\langle \bullet \rangle_m$ for modules. We are well aware that other authors do not introduce a formalism to keep track of the substructures and kind homomorphisms used, but we are convinced, that the exposition is far easier to understand, by doing so.

Notation

A, B, C	matrices, algebras and monoids
D, E, F	fields
G, H	groups and monoids
I, J, K	index sets
L, M, N	modules
P, Q	subsets and substructures
R, S, T	rings (all kinds of)
U, V, W	vector-spaces, multiplicatively closed sets
X, Y, Z	arbitrary sets
a, b, c	elements of rings
d, e	degree of polynomials, dimension
e	neutral element of a (group or) monoid
f, g, h	functions, polynomials and elements of algebras
i, j, k, l	integers and indexes
m, n	natural numbers
p, q	residue classes
r, s	further elements of rings
s, t, x	polynomial variables
u, v, w	elements of vector-spaces
x, y, z	elements of groups and modules
α, β, γ	multi-indexes
ι, κ	(canonical) monomorphisms
λ, μ	eigenvalues
μ, ν	valuation or Euclidean function
ϱ, σ	(canonical) epimorphisms
ϱ, σ, τ	permutations
φ, ψ	homomorphisms
Φ, Ψ	isomorphisms
Ω	(fixed) finite set
$\mathfrak{a}$, $\mathfrak{b}$, $\mathfrak{c}$	ideals
$\mathfrak{u}$, $\mathfrak{v}$, $\mathfrak{w}$	other ideals
$\mathfrak{p}$, $\mathfrak{q}$	prime ideals
$\mathfrak{r}$, $\mathfrak{t}$	other prime ideals
$\mathfrak{m}$, $\mathfrak{n}$	maximal ideals
$\mathfrak{f}$, $\mathfrak{g}$, $\mathfrak{h}$	fraction ideals
$\mathcal{A}$, $\mathcal{B}$, $\mathcal{C}$	(ordered) bases or families of sets
$\mathcal{M}$, $\mathcal{N}$	more (ordered) bases
$\mathcal{E}$, $\mathcal{F}$	(canonical = Euclidean) bases

Part I

The Truth

0.4 A Primer on Sets

In this book we assume that the reader already is familiar with naive set theory, nevertheless we will present the most frequently used notions here. If you had troubles understanding the concepts in the previous section this will surely help, but we will not cover set theory in any depth.
It all began with Cantor's notion of a **set**: *A "set" is a collection M into a whole of definite, distinct objects m of our perception or thought.* True to this concept Cantor wrote $x \in M$ if the object x belongs to the set M (he said is an *element* of M) and $x \notin M$ if not. For example "Tuesday" is an element of the set of days in a week. Or the reader is an element of the set of all beings that are able to read English. Sets can even be infinite: A line is the set of all points that lie on it.

According to this definition, a set is completely determined by the elements it contains. That is the sets A and B are *equal*, iff they contain precisely the same elements. More explicitly this is the case iff for any object x (of our perception or thought) we have the equivalence

$$A = B \quad :\Longleftrightarrow \quad \big(x \in A \iff x \in B\big)$$

A related notion is that of a *subset* $A \subseteq B$: Intuitively speaking, that is A is contained in B (or may even be equal, but no larger than B). More formally this can be put as: We have $A \subseteq B$ if any element x of A already is contained in B, as well

$$A \subseteq B \quad :\Longleftrightarrow \quad \big(x \in A \implies x \in B\big)$$

From these definitions it is immediately clear (as $x \in A \implies x \in B$ and $x \in B \implies x \in A$ can be combined to $x \in A \iff x \in B$), that two sets A and B are equal iff they are mutually contained in each other. That is we have

$$A = B \iff \big(A \subseteq B \text{ and } B \subseteq A\big)$$

We will often use this fact to prove $A = B$ by showing both inclusions $A \subseteq B$ and $B \subseteq A$ separately. Cantor's notion also enables us to construct new sets from existing ones: E.g. the *intersection* $A \cap B$ is the set that contains the elements x that are both in A and in B. Likewise the *union* $A \cup B$ gathers all the objects x that come from at least one of these sets. And the *difference* $A \setminus B$ contains the elements $x \in A$, yet we scratch all objects x that also belong to B. Formally

$$\begin{aligned} A \cap B &:= \{\, x \mid x \in A \text{ and } x \in B \,\} \\ A \cup B &:= \{\, x \mid x \in A \text{ or } x \in B \,\} \\ A \setminus B &:= \{\, x \mid x \in A \text{ and } x \notin B \,\} \end{aligned}$$

Though this may not be entirely satisfactory from a formal point of view (mainly because the notion of an object x remains rather vague), this concept sustained mathematics for centuries. In the next section we will even refine this concept by presenting a list of *axioms* (that is statements, that we agree upon as being true, without question) that completely describe what we may safely do with sets.

This list of axioms will be (ZFC) [an abbreviation for Zermelo, Fraenkel plus the axiom of choice] that modern mathematics almost always uses. This also is the way formal set theory took: Hereby it is not explained what a set (object x) is. It just picks up a formal language containing the relation symbol $\in$ and deduces all the other theorems from the list (ZFC). It is thereby completely defined, what we may *do* with sets, but not what a set *is*. In this context a set is just a variable symbol x of the formal language speaking of sets. If you are inclined to learn how formal logic works, we recommend Many-Sorted Logic. Later in this book (when we come to category theory) we will also use classes. Naively speaking a **class** is just an arbitrary large collection of sets. Thereby it may well happen, that a certain class is a set again (if it contains not too many sets), but we have to separate these notions in order to avoid the contradictions, a devious mind may come up with. Again we will present a list (NBG) of axioms (which abbreviates Neumann, Bernays, Gödel) that describe how to deal with classes.
From a formal point of view we have a two-sorted language - one sort for sets and the other sort for classes. Then all the other theorems are deduced from (ZFC) appended by (NBG). So again formal mathematics does not answer what a class *is*, but evades the necessity to do so. Note that we will not say a word about naive or formal logic, but take this for granted. Our main focus are relations: Partial orders, equivalence relations and functions. But beforehand let us give a few examples of the workings of sets, that we will require later on, anyway:

(0.1) Example:

(i) If both $A, B \subseteq X$ are subsets of some larger set X, then the difference $A \setminus B$ is the intersection of A with the *complement* $X \setminus B$, formally put:

$$A \setminus B \;=\; A \cap \big(X \setminus B\big)$$

Prob by definition $X \setminus B = \{\, x \in X \mid x \notin B \,\}$. And as also $A \subseteq X$ we have $A = \{\, x \in X \mid x \in A \,\}$. Therefore $A \cap (X \setminus B) = \{\, x \in X \mid x \in A \text{ and } x \notin B \,\}$ and this is $A \setminus B$, again.

(ii) The *empty set* $\emptyset$ is the one ond only set, that does not contain any element at all. That is $x \in \emptyset$ is always false. Now for any sets A and B we have the equivalence of

$$A \subseteq B \iff \big(A \setminus B = \emptyset\big)$$

Prob to say $A \subseteq B$ is false, means that there is some $a \in A$ with $a \notin B$. In other words this is $a \in A \setminus B$ and hence $A \setminus B \neq \emptyset$. Hence (the negations of) these statements are equivalent.

(iii) Consider finitely many sets $B_1, \ldots, B_n$ and let $A := B_1 \cap B_2 \cap \cdots \cap B_n$ be the intersection of all of them. Then the following two statements are equivalent:

(a) $A = B_2 \cap \cdots \cap B_n$

(b) $B_2 \cap \cdots \cap B_n \subseteq B_1$

Prob (a) $\implies$ (b) is easy: If $b \in B_2 \cap \cdots \cap B_n = A$ we find $b \in A = B_1 \cap \cdots \cap B_n \subseteq B_1$ by construction of A. Conversely for (b) $\implies$ (a) we directly see $A = B_1 \cap \cdots \cap B_n \subseteq B_2 \cap \cdots \cap B_n$. For $B_2 \cap \cdots \cap B_n \subseteq A$ consider any $a \in B_2 \cap \cdots \cap B_n \subseteq B$. Then $a \in B_1 \cap (B_2 \cap \cdots \cap B_2) = A$.

(0.2) Proposition: (viz. 682)
Let I and J be any non-empty index sets and for $i \in I$ respectively for any $j \in J$ let A_i and B_j be arbitrary sets. Also consider some sets A and B. Then we get the following identities

$$\left(\bigcup_{i\in I} A_i\right) \cap B \;=\; \bigcup_{i\in I} (A_i \cap B)$$

$$\left(\bigcap_{i\in I} A_i\right) \cup B \;=\; \bigcap_{i\in I} (A_i \cup B)$$

$$\left(\bigcup_{i\in I} A_i\right) \cap \left(\bigcup_{j\in J} B_j\right) \;=\; \bigcup_{(i,j)\in I\times J} (A_i \cap B_j)$$

$$\left(\bigcap_{i\in I} A_i\right) \cup \left(\bigcap_{j\in J} B_j\right) \;=\; \bigcap_{(i,j)\in I\times J} (A_i \cup B_j)$$

And if for any $i \in I$ we have $A_i \subseteq X$, where X is any other set, then we also find the following identities for the *complements* $X \setminus A$

$$X \setminus \bigcup_{i\in I} A_i \;=\; \bigcap_{i\in I} (X \setminus A_i)$$

$$X \setminus \bigcap_{i\in I} A_i \;=\; \bigcup_{i\in I} (X \setminus A_i)$$

Relations and Functions

(0.3) Definition:
If X and Y are any sets, then a **relation** R between these sets is just a subset of the cartesian product of X and Y, formally

$$R \;\subseteq\; X \times Y$$

We say that the elements $x \in X$ and $y \in Y$ are **related** under R, if the ordered pair $(x,y) \in X \times Y$ is contained in R. In this case we write xRy, in formal terms

$$x\,R\,y \;:\Longleftrightarrow\; (x,y) \in R$$

(0.4) Remark: (viz. 681)
The cartesian product $X \times Y$ is thought to be the set of all pairs (x,y) where $x \in X$ and $y \in Y$. Formally we could define (x,y) to be

$$(x,y) \;:=\; \{\, x, \{\, x, y \,\}\,\}$$

Using this construction it can be proved (distinguishing 8 cases and using the axiom of foundation) that for any u, $x \in X$ and any v, $y \in Y$ we have the desired property of ordered pairs

$$(u,v) \;=\; (x,y) \;\Longleftrightarrow\; u = x \text{ and } v = y$$

(0.5) Definition:
If X and Y are any sets again, then a **partial function** f is a relation between X and Y that is *right unique* in the following sense: For any $x \in X$ and any $y_1, y_2 \in Y$ we have the implication

$$x f y_1 \text{ and } x f y_2 \implies y_1 = y_2$$

In this case we will write $f : X \rightarrowtail Y$ and given $x \in X$ and $y \in Y$ we will often rewrite the relation f in the following form

$$f : x \mapsto y \quad :\Longleftrightarrow \quad x f y$$

We will denote by $f(x)$ the unique element $y \in Y$ such that xfy (if this exists). And we define the **domain** of f to be the set of all $x \in X$ that are assigned some value $y \in Y$

$$\operatorname{dom}(f) \;:=\; \{\, x \in X \mid \exists\, y \in Y : x f y \,\}$$

And a partial function is said to be a **function**, iff it is *left total* in the following sense: For any $x \in X$ there is some $y \in Y$ such that xfy. Thus a function f is a relation that satisfies

$$\forall\, x \in X \;\; \exists !\, y \in Y \;\; : \;\; x f y$$

In other words again that is $\operatorname{dom}(f) = X$. Thereby a partial function $f : X \rightarrowtail Y$ always is a function $f : \operatorname{dom}(f) \to Y$. The set of all functions from X to Y will be denoted by

$$\mathcal{F}(X,Y) \;=\; Y^X \;:=\; \{\, f \subseteq X \times Y \mid f \text{ is a function} \,\}$$

If now $A \subseteq X$ and $B \subseteq Y$ are any subsets of X and Y respectively then we define the **image** of A and **preimage** of B under f to be the following sets

$$\begin{aligned} f(A) \;&:=\; \{\, f(x) \mid x \in A \,\} \;\subseteq\; Y \\ f^{-1}(B) \;&:=\; \{\, x \in X \mid f(x) \in B \,\} \;\subseteq\; X \end{aligned}$$

(0.6) Remark:
Intuitively speaking a function is a black box, that assigns every $x \in X$ some value $y = f(x) \in Y$. To use a relation as the general framework just is a neat trick to pull functions back into the concept of sets. In fact this notion is so predominant that one oven introduces a symbol to get f back from f: The **graph** of f is defined to be

$$\Gamma(f) \;:=\; \{\, (x,y) \in X \times Y \mid y = f(x) \,\} \;=\; f$$

We will often encounter the following situation: Given sets X, Y and some $x \in X$ we define some $f(x)$. Then we need to prove that $f : X \to Y$ with $f : x \mapsto f(x)$ is a **well-defined** function $f : X \to Y$. This is to say we have to check the following properties: (1) First of all for any $x \in X$ the element $f(x)$ needs to be an element of $f(x) \in Y$. And (2) if x_1 and $x_2 \in X$ such that $x_1 = x_2$ then we need $f(x_1) = f(x_2)$. This is the right uniqueness of f. That is we have a partial function $f :\rightarrowtail Y$. If we made no restriction as to what $x \in X$ we take, f already is a function from X to Y.

(0.7) Proposition: (viz. 683)
Let X and Y be arbitrary sets, $A \subseteq X$ and $B \subseteq Y$ be subsets and consider a function $f : X \to Y$. Then we get all of the following statements

$$\begin{array}{rcl} A & \subseteq & f^{-1}\big(f(A)\big) \\ f(X) \cap B & = & f\big(f^{-1}(B)\big) \\ X \setminus f^{-1}(B) & = & f^{-1}\big(Y \setminus B\big) \\ f(A) \subseteq B & \iff & A \subseteq f^{-1}(B) \end{array}$$

In particular $f\big(f^{-1}(B)\big) \subseteq B$. If now $\mathcal{A} = \{ A_i \mid i \in I \}$ is an entire collection of subsets $A_i \subseteq X$ and $\mathcal{B} = \{ B_j \mid j \in j \}$ be a collection of subsets of Y, then we further get

$$\begin{array}{rcl} f^{-1}\left(\bigcup\limits_{j\in J} B_j\right) & = & \bigcup\limits_{j\in J} f^{-1}(B_j) \\ f^{-1}\left(\bigcap\limits_{j\in J} B_j\right) & = & \bigcap\limits_{j\in J} f^{-1}(B_j) \\ f\left(\bigcup\limits_{i\in I} A_i\right) & = & \bigcup\limits_{i\in I} f(A_i) \\ f\left(\bigcap\limits_{i\in I} A_i\right) & \subseteq & \bigcap\limits_{i\in I} f(A_i) \end{array}$$

($\diamondsuit$) Note that in the cases where we have an inclusion $\subseteq$ only, then equality need not be true in general. However if f is *injective* (see below), then in both cases we have the equality of sets

$$\begin{array}{rcl} A & = & f^{-1}\big(f(A)\big) \\ f\left(\bigcap\limits_{i\in I} A_i\right) & = & \bigcap\limits_{i\in I} f(A_i) \end{array}$$

(0.8) Definition:
Let now X, Y and Z be sets, $A \subseteq X$ be a subset and consider the functions $f : X \to Y$ and $g : Y \to Z$. First of all we define the **restriction** of f to A to be the following function

$$f\big|_A \;:=\; \{ (x,y) \mid x \in A,\, y = f(x) \}$$

In particular the restriction $f|_A$ is a function of the form $A \to Y$ given by $f|_A : x \mapsto f(x)$. And we also define the **composition** gf of g **after** f to be the following function

$$gf \;:=\; \{ (x,z) \in X \times Z \mid \exists\, y \in Y \,:\, y = f(x) \text{ and } z = g(y) \}$$

In particular gf is a function of the form $X \to Z$ that takes $x \in X$ to $y = f(x) \in Y$ and further on to $z = g(y) \in Z$. That is we can write

$$gf \;:\; X \to Z \;:\; x \;\mapsto\; g\big(f(x)\big)$$

(0.9) Remark:
Note that thereby the composition of maps is associative: That is for any chain of functions $f : U \to X$, $g : X \to Y$ and $h := Y \to Z$ we get $(hg)f = h(gf)$ as for any $u \in U$ we have

$$\big((hg)f\big)(u) \;=\; hg\big(f(u)\big) \;=\; h\big(g\big(f(u)\big)\big) \;=\; h\big(gf(u)\big) \;=\; \big(h(gf)\big)(u)$$

(0.10) Definition: (viz. 685)
Let X and Y be arbitrary sets, $f : X \to Y$ be a function from X to Y. Then f is said to be **injective**, iff it satisfies any one of the following four equivalent properties. And in this case we write $f : X \hookrightarrow Y$.

(a) The function f admits a *left-inverse*, that is there is some function $g : Y \to X$ such that the composition satisfies

$$gf \;=\; \mathbb{1}_X$$

(b) Separate points of X will be assigned separate points in Y: That is for any u, $x \in X$ we obtain the following implication

$$f(u) \;=\; f(x) \quad\Longrightarrow\quad u \;=\; x$$

(c) For any subset $A \subseteq X$ the preimage of the image of A is just A again

$$f^{-1}\big(f(A)\big) \;=\; A$$

(d) Every *fiber* of f contains at most one element: That is for any $y \in Y$

$$\#f^{-1}\big(\{y\}\big) \;\leq\; 1$$

And $f : X \to Y$ is said to be **surjective**, iff it satisfies any one of the following four equivalent properties. Likewise we introduce the notation $f : X \twoheadrightarrow Y$ to abbreviate (emphasize) this case.

(a) The function f admits a *right-inverse* that is there is some function $g : Y \to X$ such that the composition satisfies

$$fg \;=\; \mathbb{1}_Y$$

(b) The function f reaches the entire set Y, that is the *image* of f is Y

$$f(X) \;=\; Y$$

(c) For any subset $B \subseteq Y$ the image of the preimage of B is just B again

$$f\big(f^{-1}(B)\big) \;=\; B$$

(d) Every *fiber* of f contains at least one element: That is for any $y \in Y$

$$\#f^{-1}\big(\{y\}\big) \;\geq\; 1$$

Finally $f : X \to Y$ is said to be **bijective**, iff it satisfies any one of the following four equivalent properties. And in this case we write $f : X \longleftrightarrow Y$.

(a) The function f is a one-to-one correspondence between the elements of X and the elements of Y, that is for any $y \in Y$ there is a uniquely determined $x \in X$ such that $y = f(x)$. Formally

$$\forall\, y \in Y \;\; \exists !\, x \in X \;\; : \;\; y \;=\; f(x)$$

(b) The function f has a uniquely defined **inverse function** $f^{-1} : Y \to X$ whose compositions satisfy

$$f^{-1}f \;=\; \mathbb{1}_X \quad \text{and} \quad ff^{-1} \;=\; \mathbb{1}_Y$$

(c) The function f admits both, a *left-inverse* function $\ell : Y \to R$ and a *right-inverse* function $r : Y \to X$ that is ℓ and r satisfy the properties

$$\ell f \;=\; \mathbb{1}_X \quad \text{and} \quad fr \;=\; \mathbb{1}_Y$$

(d) The function f is both: injective and bijective.

(0.11) Remark:
For the time being f^{-1} is just a peculiar name for the inverse function of f. It has the advantage of designating the function f it came from however. This is useful as [due to the symmetry of property (b)] f is the inverse function of f^{-1}. Later we will denote the inverse element of some element $x \in G$ of a group G by x^{-1}. This is consistent, as f^{-1} is precisely the inverse element of f in the group of bijective functions from X to Y.

Equivalence Relations

(0.12) Definition:
Let X be a set and consider an arbitrary collection $\mathcal{A} = \{\, A_i \mid i \in I \,\}$ of subsets $A_i \subseteq X$. Then we say that $\mathcal{A}$ is a **partition** of X iff the $A_i \in \mathcal{A}$ are non-empty, pairwise disjoint and X is the grand union of $\mathcal{A}$. That is we get the following properties

$$\begin{array}{lrcl}
(1) & \forall\, A_i \in \mathcal{A} & : & A_i \neq \emptyset \\
(2) & \forall\, A_i, A_j \in \mathcal{A} & : & A_i \cap A_j \neq \emptyset \implies A_i = A_j \\
(3) & X & = & \bigcup_{i \in I} A_i
\end{array}$$

And a relation of the form $\sim \;\subseteq\; X \times X$ is said to be an **equivalence relation** iff it is reflexive, symmetric and transitive. That is for any x, y and $z \in X$ we find the following properties for $\sim$

$$\begin{array}{lrcl}
(1) & & & x \sim x \\
(2) & x \sim y & \implies & y \sim x \\
(3) & x \sim y,\; y \sim z & \implies & x \sim z
\end{array}$$

If $\sim$ is an equivalence relation on X and $x \in X$ is any element, then we define the **equivalence class** of x to be the following subset of X

$$[x] \;:=\; \{\, u \in X \mid u \sim x \,\}$$

Note that (by construction of the equivalence classes $[x]$) for any $x, y \in X$ the following statements are equivalent (a) $x \sim y$, (b) $[x] = [y]$ and (c) $x \in [y]$. And the collection of all equivalence classes of $\sim$ will be denoted as (note that the definition of this set will most certainly contain redundancies $[u] = [x]$)

$$X\big/_{\sim} \;:=\; \{\, [x] \mid x \in X \,\}$$

(0.13) Lemma: (viz. 686)
If $X \neq \emptyset$ is a non-empty set then there is a one-to-one correspondence between the partitions of X and the equivalence relations on X. That is if we denote the sets

$$\begin{aligned} \mathrm{part}(X) &:= \{\, \mathcal{A} \subseteq \mathcal{P}(X) \mid \mathcal{A} \text{ is a partition} \,\} \\ \mathrm{equi}(X) &:= \{\, \sim \subseteq X \times X \mid \sim \text{ is an equivalence relation} \,\} \end{aligned}$$

then the following map from the set of equivalence relations on X to the set of partitions of X is well-defined and bijective

$$\mathrm{equi}(X) \;\longleftrightarrow\; \mathrm{part}(X) \;:\; \sim \;\mapsto\; X\big/_{\sim}$$

Thereby the inverse function of this map is given by the following construction: If $\mathcal{A}$ is a partition of X and $u, x \in X$ we define the relation

$$u \sim_{\mathcal{A}} x \quad :\Longleftrightarrow \quad \exists\, A \in \mathcal{A} \;:\; \{\, u, x \,\} \;\subseteq\; A$$

(0.14) Remark:
Equivalence relations are *the* primary tool to isolate a problem or property. And they frequently call for a check of *well-definedness* of a function: Consider any two sets X and Y, a function $f : X \to Y$ and an equivalence relation $\sim$ on X. Then we say that f *factors* through $\sim$, iff for any $x, y \in X$ we get

$$x \sim y \quad \Longrightarrow \quad f(x) \,=\, f(y)$$

Let us denote the quotient set $A := X/\sim$, then this property enables us to define a function $\overline{f} : A \to Y$ by letting $\overline{f}(a) := f(x)$ where $a = [x]$ for some $x \in X$. Note that the factors-property is exactly what we need to guarantee, that $f(x)$ does not depend on the choice of the specific $x \in a \in A$. Also note that - by going to equivalence classes - the factors-property of f is just the same, as the well-definedness-property of $\overline{f}$. The latter reads as: For any $a, b \in A$ we have

$$a \,=\, b \quad \Longrightarrow \quad \overline{f}(a) \,=\, \overline{f}(b)$$

This is the standard case, when we say that we need to check the well-definedness of a function $\overline{f}$ defined on equivalence classes. And while this actually is the second implication for a and b, this is just an equivalent formulation of the first implication for x and y. And it is this first formulation, that we will verify to get the well-definedess of $\overline{f}$.

(0.15) Example:
If X and Y are sets, $f : X \to Y$ is any function, then we obtain an equivalence relation $\sim_f$ of X by defining (for any $u, y \in X$)

$$u \sim_f x \quad :\Longleftrightarrow \quad f(u) \;=\; f(x)$$

It is clear that this relation is reflexive, symmetric and transitive (as the equality relation $=$ satisfies all these properties). And for any $x \in X$ the equivalence of x is precisely the fibre of $f(x) \in Y$, that is

$$[x] \;=\; f^{-1}\big(\,\{\,f(x)\,\}\,\big) \;\subseteq\; X$$

In this case it is clear - by construction - that f factors through $\sim_f$ and thereby we obtain a well-defined, even injective, function $\overline{f}$ on the set of quotients

$$\overline{f} \;:\; X\Big/_{\sim} \;\hookrightarrow\; Y \;:\; [x] \mapsto f(x)$$

(0.16) Remark:
If $\sim$ is an equivalence relation on the set X, then the set $X/\sim$ of equivalence classes is a partition of X. In particular any $A \in X/\sim$ is non-empty and hence the axiom of choice guarantees, that there is a set $R \subseteq X$ such that we have a one-to-one correspondence

$$R \;\longleftrightarrow\; X\Big/_{\sim} \;:\; x \mapsto [x]$$

Such a set R is called a **system of representatives** of the relation $\sim$. And with such a system we have (without redundancies this time)

$$X\Big/_{\sim} \;=\; \{\,[x] \mid x \in R\,\}$$

Partial and Total Orders

(0.17) Definition:
Let X be a set and $\leq \subseteq X \times X$ be a relation on X. Then we say that $\leq$ is a **partial order** on X, iff it is reflexive, transitive and antisymmetric. That is for any x, y and $z \in X$ we find the properties

$$\begin{array}{lll} (1) & & x \leq x \\ (2) & x \leq y,\; y \leq z & \Longrightarrow \quad x \leq z \\ (3) & x \leq y,\; y \leq x & \Longrightarrow \quad x = y \end{array}$$

In this case, if $A \subseteq X$ is any subset, we define the abbreviations $x \leq A \;:\Longleftrightarrow\; \forall\, a \in A : x \leq A$ and $A \leq x \;:\Longleftrightarrow\; \forall\, a \in A : a \leq x$. And a partial order $\leq$ is said to be a **total order** or alternatively **linear order**, iff it satisfies the following fourth property

$$(4)\;\; \forall\, x, y \in X \;\;:\;\; x \leq y \;\text{ or }\; y \leq x$$

If $\leq$ is a partial [resp. total] order, then the pair $(X, \leq)$ is called a **partially ordered** [resp. **totally ordered**] **set**. In the literature this is sometimes abbreviated as *poset* or *toset* respectively. In any case a subset $N \subseteq X$ is said to be a **net** in $(X, \leq)$ iff every two elements of N have a common greater element, that is

$$\forall\, x, y \in N \;\; \exists z \in N \;\; : \;\; x \leq z \;\text{ and }\; y \leq z$$

And a subset $C \subseteq X$ said to be a **chain** in $(X, \leq)$ iff is a totally ordered set under the order $\leq$ inherited from X. That is iff for any two elements of C we can decide which one is the greater, formally

$$\forall\, x, y \in C \;\; : \;\; x \leq y \;\text{ or }\; y \leq x$$

Let us denote the set of all nets, resp. of all chains resp. of all finite chains in $(X, \leq)$ by $\mathcal{N}(X, \leq)$, $\mathcal{C}(X, \leq)$ and $\mathcal{C}_0(X, \leq)$, that is we denote the following collections of subsets of X

$$\begin{aligned} \mathcal{N}(X, \leq) &:= \{\, N \subseteq X \mid C \text{ net} \,\} \\ \mathcal{C}(X, \leq) &:= \{\, C \subseteq X \mid C \text{ chain} \,\} \\ \mathcal{C}_0(X, \leq) &:= \{\, C \subseteq X \mid C \text{ chain}, \#C < \infty \,\} \end{aligned}$$

Any chain already is a net [given $x, y \in C$ just let $z := \max\{ x, y \}$ then $x \leq z$ and $y \leq z$ are obvious], therefore these sets satisfy the inclusions

$$\mathcal{C}_0(X, \leq) \;\subseteq\; \mathcal{C}(X, \leq) \;\subseteq\; \mathcal{N}(X, \leq)$$

Finally if $A \subseteq X$ is any subset and $(X, \leq)$ is a partially ordered set again, then we define the following notions concerning elements of X

(i) An element $g \in X$ is called the **greatest element** of A iff $g \in A$ and for any $a \in A$ we have $a \leq g$. If it exists the greatest element of A is uniquely determined and will be denoted

$$\max(A) \;:=\; g$$

An element $\ell \in X$ is called the **least element** of A iff $\ell \in A$ and for any $a \in A$ we have $\ell \leq a$. If it exists the least element of A is uniquely determined and will be denoted

$$\min(A) \;:=\; \ell$$

Prob suppose both g and g' are greatest elements of A. As $g \in A$ and g' is a greatest element we have $g \leq g'$. Vice versa we have $g' \leq g$. So by anti-symmetry of $\leq$ we find $g = g'$. The same reasoning can be applied to the least elements of A.

(ii) An element $m \in X$ is called a **maximal element** of A iff $m \in A$ and for any $a \in A$ we have the implication $m \leq a \implies a = m$. The set of maximal elements of A will be denoted by

$$A^* \;:=\; \{\, m \in A \mid \forall\, a \in A : m \leq a \implies a = m \,\}$$

Likewise an element $m \in X$ is called a **minimal element** of A iff $m \in A$ and for any $a \in A$ we have the implication $a \leq m \implies a = m$. The set of minimal elements of A will be denoted by

$$A_* \;:=\; \{\, m \in A \mid \forall\, a \in A : a \leq m \implies a = m \,\}$$

(0.18) Remark:

(i) Let X be any set, recall the definition of the **power set** to be the set of all subsets of X, that is

$$\mathcal{P}(X) \;=\; \{\, A \mid A \subseteq X \,\}$$

A special case is the power set of the empty set, which is $\mathcal{P}(\emptyset) = \{\emptyset\}$. And e.g. for $X = \{1,2,3\}$ the power set is given to be

$$\mathcal{P}(X) \;=\; \{\emptyset,\, \{1\},\, \{2\},\, \{3\},\, \{1,2\},\, \{1,3\},\, \{2,3\},\, X\}$$

In general $\mathcal{P}(X)$ contains $2^{|X|}$ elements. Thereby $(\mathcal{P}(X), \subseteq)$ is a partially ordered set for any set X, however $\subseteq$ is not a total order. This can already be seen in the example here: The subsets $\{1,2\}$ and $\{1,3\}$ of X are not *comparable* under $\subseteq$, as we neither have $\{1,2\} \subseteq \{1,3\}$ nor $\{1,3\} \subseteq \{1,2\}$. Thus $\subseteq$ is not a total order on X.

(ii) If $(X, \leq)$ is a partially [resp. totally] ordered set and $A \subseteq X$ is a subset, then the restriction $(\leq \cap\, A \times A) \subseteq A \times A$ is a partial [resp. total] order on A. That is for any $a, b \in A$ we let $a \leq b$ be true, if and only $a \leq b$ when we regard a and b as elements of X. By abuse of notation we write $\leq$ for the restricted order as well, that is $(A, \leq)$ is a partially [resp. totally] ordered set again.

(iii) In particular any collection $\mathcal{A} \subseteq \mathcal{P}(X)$ of subsets of an arbitrary set X is partially ordered under inclusion $\subseteq$ again, that is

$$(\mathcal{A}, \subseteq) \text{ is a partially ordered set}$$

(iv) Let us continue with the example $X = \{1,2,3\}$ and regard the collection $\mathcal{A} := \mathcal{P}(X) \setminus \{\emptyset, X\}$ of non-trivial subsets of X. Explicitly this $\mathcal{A}$ is given to be

$$\mathcal{A} \;=\; \{\{1\},\, \{2\},\, \{3\},\, \{1,2\},\, \{1,3\},\, \{2,3\}\}$$

Then $\mathcal{A}$ has 3 maximal elements, namely $\{1,2\}$, $\{1,3\}$ and $\{2,3\}$. That is the set of maximal elements of $\mathcal{A}$ is given to be the following subset of $\mathcal{A}$

$$\mathcal{A}^* \;=\; \{\{1,2\}, \{1,3\}, \{2,3\}\}$$

(v) (■) Probably the most important example of all are the natural numbers $\mathbb{N}$. They admit an ordering $m \leq n \;:\Longleftrightarrow\; \exists\, k \in \mathbb{N} : m + k = n$ that even is a well-ordering. That is any non-empty subset $N \subseteq \mathbb{N}$ has a least element. The reader is asked to consult any textbook on "numbers" for a construction of $\mathbb{N}$ and a proof of this theorem.

(0.19) Proposition: (viz. 687)
If $(X, \leq)$ is a partially ordered set and $F \subseteq X$ is a non-empty, finite subset of X, then F contains at least one maximal and one minimal element

$$F^* \neq \emptyset \quad \text{and} \quad F_* \neq \emptyset$$

If $(X, \leq)$ is a totally ordered set and $F \subseteq X$ is a non-empty, finite subset of X, then F has both a greatest and a least element

$$\exists!\, g, \ell \in F \;:\; \max(F) = g \;\text{ and }\; \min(F) = \ell$$

(0.20) Proposition: (viz. 688)
If $(X, \leq)$ is a totally ordered set and $x_1, \ldots, x_n \in X$ are finitely may elements of X (where $2 \leq n \in \mathbb{N}$), then the minimum and maximum of $\{ x_1, \ldots, x_n \}$ can be evaluated sequentially. Formally this means

$$\min\{ \min\{ x_1, \ldots, x_{n-1} \}, x_n \} \;=\; \min\{ x_1, \ldots, x_n \} \;=\; \min\{ x_1, \min\{ x_2, \ldots, x_n \} \}$$

$$\max\{ \max\{ x_1, \ldots, x_{n-1} \}, x_n \} \;=\; \max\{ x_1, \ldots, x_n \} \;=\; \max\{ x_1, \min\{ x_2, \ldots, x_n \} \}$$

Nota if we denote the minimum of two elements $x, y \in X$ by $x \wedge y := \min\{ x, y \} \in X$ and likewise the maximum, by $x \vee y := \max\{ x, y \}$, then in particular we find the *associativity* of the operations $\wedge$ and $\vee$

$$(x \wedge y) \wedge z \;=\; x \wedge (y \wedge z) \quad \text{and} \quad (x \vee y) \vee z \;=\; x \vee (y \vee z)$$

(0.21) Proposition: (viz. 688)
If $(X, \leq)$ is a partially ordered set and for any $i \in I$ we consider a chain $C_i \in \mathcal{C}(X, \leq)$ (where $I \neq \emptyset$ is an arbitrary index set), then their intersection is a chain in X again

$$\bigcap_{i \in I} C_i \;\in\; \mathcal{C}(X, \leq)$$

Now suppose the C_i not only are chains, but that $\{ C_i \mid i \in I \}$ also is a net under inclusion [i.e. it is a net in the partially ordered set $(\mathcal{P}(X), \subseteq)$] then their union is a chain in X, as well

$$\bigcup_{i \in I} C_i \;\in\; \mathcal{C}(X, \leq)$$

0.5 Some Tools from Set Theory

After we have introduced the basic concepts of naive set theory (how to use sets, functions, equivalence relations an partial orders) let us dig a little deeper: Some concepts of algebra are general truisms on the level of sets, already, like chain conditions and Galois connections. In the algebraic setting these basic concepts will only be enriched by additional properties or equivalences.
On the other hand set theory provides some very powerful tools, that we really need. Primarily the lemma of Zorn, which provides the most often used construction, right after equivalence relations. And finally don't want to start without going into a little more detail when it comes to comparing cardinalities.
Let us start with an easy concept: Galois connections. The relation between sets of polynomials and their common roots will be a Galois connection. Likewise the transfer of ideals in ring-extensions and the relation between prime ideals over an ideal and their intersection. And lastly the relation between intermediate fields and their Galois group will be a Galois connection - this is where the name comes from. Most of these connections will be contra-variant, so the covariant case is of lesser interest to us. Also it just is the same thing without reversing the order - not a genuinely new concept. As is we have three good reasons to study Galois connections in general:

Galois Connections

If $(X,\leq)$ and $(Y,\leq)$ are partially ordered set then a function $f : X \to Y$ is said to be *monotonous*, iff $x \leq y$ implies $f(x) \leq f(y)$. In other words f is *order-preserving*. If conversely $x \leq y$ implies $f(x) \geq f(y)$, then f is said to be *antitonous* or *order-reversing*. The following situation (this might come as a surprise) is rather commonplace - we will encounter it several times:

(0.22) Definition: (viz. 688)
Let $(X,\leq)$ and $(Y,\leq)$ be two partially ordered sets and let $f : X \to Y$ and $g : Y \to X$ be two *order-reversing* functions, that is for any x, $x' \in X$ and any y, $y' \in Y$ we have the implications

$$\begin{aligned} x \leq x' &\implies f(x') \leq f(x) \\ y \leq y' &\implies g(y') \leq g(y) \end{aligned}$$

Then the following three statements are equivalent. And in this case we say that (f,g) is a **Galois connection** between $(X,\leq)$ and $(Y,\leq)$:

(a) $\forall\, x \in X, \forall\, y \in Y \;:\; x \leq g(y) \iff y \leq f(x)$

(b) $\forall\, x \in X, \forall\, y \in Y \;:\; x \leq gf(x)$ and $y \leq fg(y)$

(c) For any $x \in X$ the element $f(x) \in Y$ is the greatest element of Y, that satisfies $x \leq g(y)$ and likewise for g. That is (for any $x \in X$ and any $y \in Y$) we have

$$\begin{aligned} f(x) &= \max\{\, y \in Y \mid x \leq g(y) \,\} \\ g(y) &= \max\{\, x \in X \mid y \leq f(x) \,\} \end{aligned}$$

And in this case these maps satisfy $fgf = f$ and $gfg = g$. In other words the functions f and g give rise to a one-to-one correspondence between their respective image sets. The following map is bijective:

$$\begin{array}{rcl} g(Y) & \longleftrightarrow & f(X) \\ x & \mapsto & f(x) \\ g(y) & \hookleftarrow & y \end{array}$$

(0.23) Example:
The properties $fgf = f$ and $gfg = g$ alone do not suffice for a Galois connection however. As an example take $X := \{1,2,3\}$ and $Y := \{1,2\}$ under the natural order of $\mathbb{N}$. Then define f by $f(1) := 2$, $f(2) := 1$ and $f(3) := 1$. Likewise $g(1) := 2$ and $g(2) := 1$. Then straightforward to check that we get the one-to-one correspondence $\{1,2\} \longleftrightarrow \{1,2\}$ but $gf(3) = 2$ does not satisfy $3 \leq gf(3)$, that is (b) is not satisfied.

(0.24) Remark:
The above version of a Galois connection is *contra-variant*. There also is a *covariant* version, in which $f : X \to Y$ and $g : Y \to X$ are two *order-preserving* functions, that is for any x, $x' \in X$ and any y, $y' \in Y$ we have the implications

$$\begin{array}{rcl} x \leq x' & \Longrightarrow & f(x) \leq f(x') \\ y \leq y' & \Longrightarrow & g(y) \leq g(y') \end{array}$$

Then the following three statements are equivalent. And in this case we say that (f,g) is a **Galois connection** between $(X,\leq)$ and $(Y,\leq)$:

(a) $\forall\, x \in X, \forall\, y \in Y \;:\; f(x) \leq y \iff x \leq g(y)$

(b) $\forall\, x \in X, \forall\, y \in Y \;:\; x \leq gf(x)$ and $fg(y) \leq y$

(c) For any $x \in X$ the element $f(x) \in Y$ is the least element of Y, that satisfies $x \leq g(y)$ and $g(y)$ is the greatest element of X, that satisfies $f(x) \leq y$. That is (for any $x \in X$ and any $y \in Y$) we have

$$\begin{array}{rcl} f(x) & = & \min\{\, y \in Y \mid x \leq g(y) \,\} \\ g(y) & = & \max\{\, x \in X \mid f(x) \leq y \,\} \end{array}$$

And in this case these maps satisfy $fgf = f$ and $gfg = g$. In other words the functions f and g give rise to a one-to-one correspondence between their respective image sets, just as in the contra-variant case:

$$\begin{array}{rcl} g(Y) & \longleftrightarrow & f(X) \\ x & \mapsto & f(x) \\ g(y) & \hookleftarrow & y \end{array}$$

(0.25) Definition: (viz. 689)
Let $(X, \leq)$ be a partially ordered set, then we say that $(X, \leq)$ satisfies the **ascending chain condition** (which we will always abbreviate by **ACC**), iff it satisfies one of the following two equivalent properties

(a) Any non-empty $A \neq \emptyset$ subset $A \subseteq X$ of X has a maximal element. That is there is some $a^* \in A$ such that

$$\forall\, a \in A \;:\; a \leq a^* \implies a = a^*$$

(b) Any ascending chain within X stabilizes, that is for any $(x_k) \subseteq X$ (where $k \in \mathbb{N}$) such that $x_0 \leq x_1 \leq x_2 \leq \ldots$ we have

$$\exists\, s \in \mathbb{N}\ \forall\, i \in \mathbb{N} \;:\; x_{s+i} = x_s$$

In complete analogy we we say that $(X, \leq)$ satisfies the **descending chain condition** (which we will always abbreviate by **DCC**), iff it satisfies one of the following two equivalent properties

(a) Any non-empty $A \neq \emptyset$ subset $A \subseteq X$ of X has a minimal element. That is there is some $a_* \in A$ such that

$$\forall\, a \in A \;:\; a_* \leq a \implies a = a_*$$

(b) Any descending chain within X stabilizes, that is for any $(x_k) \subseteq X$ (where $k \in \mathbb{N}$) such that $x_0 \geq x_1 \geq x_2 \geq \ldots$ we have

$$\exists\, s \in \mathbb{N}\ \forall\, i \in \mathbb{N} \;:\; x_{s+i} = x_s$$

(0.26) Lemma: (viz. 690)
Let $(X, \leq)$ be a partially ordered set and recall that $\mathcal{C}(X, \leq)$ denotes the set of all chains, $\mathcal{C}_0(X, \leq)$ denotes the set of finite chains of $(X, \leq)$. Then the following three statements are equivalent

(a) $(X, \leq)$ satisfies both ACC and DCC

(b) $(\mathcal{C}_0(X, \leq), \subseteq)$ satisfies ACC

(c) Every chain in $(X, \leq)$ is finite, that is the have the equality of the sets

$$\mathcal{C}(X, \leq) \;=\; \mathcal{C}_0(X, \leq)$$

And in this case any chain in $(X, \leq)$ can be refined to a maximal finite chain, that is: If $C \subseteq X$ is a chain in $(X, \leq)$, then there is some $C^* \in \mathcal{C}_0(X, \leq)$ such that $C \subseteq C^*$ and

$$\forall\, D \in \mathcal{C}(X, \leq) \;:\; C^* \subseteq D \implies C^* = D$$

(0.27) Theorem: (viz. 691)
Hausdorff's Maximum Principle: Let $(X, \leq)$ be a partially ordered set, then there is a chain maximal $M \subseteq X$ in X (i.e. a maximal element of $\mathcal{C}(X, \leq)$ ordered under inclusion):

$$\forall C \in \mathcal{C}(X, \leq) \,:\, M \subseteq C \implies C = M$$

(0.28) Corollary: (viz. 694)
Lemma of Zorn: Let $(Z, \leq)$ be a partially ordered set, such that the following two properties are satisfied (1) $Z \neq \emptyset$ is non-empty and (2) every chain in Z has an upper bound, that is: For any $C \subseteq Z$ there is some $u \in Z$ such that for any $c \in C$ we have $c \leq u$. Then Z already has a maximal element, that is: for some $m \in Z$ any $z \in Z$ satisfies $m \leq z \implies m = z$. Formally:

$$\text{if } \forall C \in \mathcal{C}(Z, \leq)\, \exists u \in Z \,:\, \forall c \in C \,:\, c \leq u$$

$$\text{then } \exists m \in Z\, \forall z \in Z \,:\, m \leq z \implies z = m$$

(0.29) Remark:
We will mostly use the following special case of Zorn's Lemma: Let X be any set and $\mathcal{Z} \subseteq \mathcal{P}(X)$ be a non-empty $\mathcal{Z} \neq \emptyset$ family of subsets of X such that with any chain in $\mathcal{C} \subseteq \mathcal{Z}$ the union $\bigcup \mathcal{C} \in \mathcal{Z}$ is contained in $\mathcal{Z}$ as well, then $\mathcal{Z}$ has a maximal element: That is there is some $M \in \mathcal{Z}$ such that for any $Z \in \mathcal{Z}$ we have $M \subseteq Z \implies Z = M$. Formally again

$$\text{if } \forall \mathcal{C} \in \mathcal{C}(\mathcal{Z}, \subseteq) \,:\, \bigcup \mathcal{C} \in \mathcal{Z}$$

$$\text{then } \exists M \in \mathcal{Z}\, \forall Z \in \mathcal{Z} \,:\, M \subseteq Z \implies Z = M$$

Prob $(\mathcal{Z}, \subseteq)$ is a partially ordered set, such that $\mathcal{Z} \neq \emptyset$ if now $\mathcal{C} \subseteq \mathcal{Z}$ is a chain, then we let $U := \bigcup \mathcal{C}$. By assumption we have $U \in \mathcal{Z}$ and $C \subseteq U$ for any $C \in \mathcal{C}$ is clear. Then the lemma of Zorn yields $M \in \mathcal{Z}$.

We will use the lemma of Zorn to prove the existence of maximal ideals and modules with all kinds of properties. It can also be used to construct partial functions with maximal domain and so on. It is the single most powerful tool at or disposal! But though it is easy to use and very versatile (due to its generality) it only grants the existence of a maximal element. It does neither tell us how to find nor how to construct it. All we know, is that there *is* some.

(0.30) Theorem: (viz. 694)
Well-ordering Theorem: Let X be any set, then there is a total order $\leq$ on X that even satisfies the following *well-ordering* property: For any non-empty subset $A \subseteq X$, $A \neq \emptyset$ there is a *least element* $m \in A$, formally that is

$$\exists m \in A \;:\; \forall a \in A \;:\; m \leq a$$

(0.31) Remark:
These are the three basic theorems of set theory. And if we take a close look at the proofs [the reader is *not* required to do so, in order to be a good mathematician, but an understanding of the content of the theorems *is* required] we see that Hausdorff's maximum principle is derived from the axiom of choice, Zorn's lemma is derived from the maximum principle and the well-ordering theorem is derived from Zorn's lemma. We just want to sketch the idea that we can go full circle: The axiom of choice can be derived from the well-ordering theorem easily: Given an arbitrary collection $\mathcal{A} = \{ A_i \mid i \in I \}$ of non-empty sets $A_i \neq \emptyset$ we can construct a choice function in the following way: Let $A := \bigcup_i A_i$ and $X := \bigcup_i \{ i \} \times A_i \subseteq \mathcal{P}(I \times A)$ be the *disjoint union* of the A_i. Now install a well-ordering $\leq$ on X, then we may define a choice function $f : \mathcal{A} \to A$ by letting $f(A_i) := x_i$ where x_i is the minimum of the set $\{ i \} \times A_i \subseteq X$ under $\leq$, formally $(i, x_i) = \min(\{ i \} \times A_i)$. Therefore these three properties are equivalent on the basis of the other axioms of set theory. It is a different story, that they even are independent of the other axioms of set theory, that is they can neither be proved nor falsified. But this result requires much more effort in formal logic.

Comparing Cardinalities

(0.32) Lemma: (viz. 696)
Let X and Y be any two sets and let us agree two write $X \hookrightarrow Y$ iff there is an injective function f of the form $f : X \to Y$. Likewise we write $Y \twoheadrightarrow X$ iff there is a surjective function g of the form $g : Y \to X$. Finally we write $X \longleftrightarrow Y$ if there is a bijective function b of the form $b : X \to Y$. Using these notations we get the following statements

(i) For any two sets X and Y the properties $X \hookrightarrow Y$ and $Y \twoheadrightarrow X$ are equivalent.

(ii) For any two non-empty sets $X, Y \neq \emptyset$ we always have $X \hookrightarrow Y$ or $Y \hookrightarrow X$ (or both).

(iii) *Bernstein's Equivalence Theorem*: For any two sets X and Y we have the equivalence of

 (a) $X \longleftrightarrow Y$

 (b) $X \hookrightarrow Y$ and $Y \hookrightarrow X$

(0.33) Remark:
The benefit of these theorems is far reaching indeed: Note that we have defined the cardinal $|X|$ as $\{ Y \mid X \longleftrightarrow Y \}$. In particular $|\emptyset| = \emptyset$ (as $\emptyset$ does not admit a function, at all). And for any set with $1 \leq n \in \mathbb{N}$ elements $|X|$ contains all sets with exactly n elements.
Generally speaking $|X|$ is something like the equivalence class of X under the equivalence relation $\longleftrightarrow$, with the slight technical problem, that it only is a class, not a set. Thus $0 = \emptyset$ is the canonical representative of $|\emptyset|$ and n is the canonical representative of $|\{ 1, \ldots, n \}|$. Regardless, what is important is comparing cardinals: Recall that we have defined

$$
\begin{aligned}
|X| \leq |Y| \quad &:\Longleftrightarrow \quad X = \emptyset \text{ or } \exists\, f : X \to Y \text{ such that } f \text{ is injective} \\
|Y| \geq |X| \quad &:\Longleftrightarrow \quad X = \emptyset \text{ or } \exists\, g : Y \to X \text{ such that } g \text{ is surjective} \\
|X| = |Y| \quad &:\Longleftrightarrow \quad X = \emptyset = Y \text{ or } \exists\, b : X \to Y \text{ such that } f \text{ is bijective}
\end{aligned}
$$

That is $|X| \leq |Y|$ is another symbol for $X \hookrightarrow Y$, $|Y| \geq |X|$ is another symbol for $Y \twoheadrightarrow X$ and $|X| = |Y|$ is another symbol for $X \longleftrightarrow Y$. And by (0.32.(i)) $|X| \leq |Y|$ is equivalent to $|Y| \geq |X|$. So the usual notation for the inverse relation is respected. Now (0.32) is the reason that $\leq$ acts like a total order between the symbols $|X|$. That is for any sets X, Y and Z [this will be proved as (iv) in (0.32)] we have

$$\begin{gathered} |X| = |X| \\ |X| \leq |Y| \text{ or } |Y| \leq |X| \\ |X| \leq |Y| \text{ and } |Y| \leq |Z| \implies |X| \leq |Z| \\ |X| \leq |Y| \text{ and } |Y| \leq |X| \implies |X| = |Y| \end{gathered}$$

(0.34) Definition:
Recall that a set A is said to be **finite**, iff it only contains finitely many elements, that is iff it is empty or of the form $A = \{ a_1, \ldots, a_n \}$ for some $n \in \mathbb{N}$. Likewise A is said to be **infinite**, iff the natural numbers $\mathbb{N}$ fit into A injectively $\mathbb{N} \hookrightarrow A$. We will study different kinds of infinity: A is said to be **countably infinite**, iff it is of the form $A = \{ a_k \mid k \in \mathbb{N} \}$ (for some elements a_k with $a_k = a_l \implies k = l$). A set that is finite or countably infinite is said to be **countable** and if A is not countable, then it is called **uncountable**. We can put all this formally in a neat, compact form

$$\begin{aligned} A \text{ finite} &:\Longleftrightarrow \exists\, n \in \mathbb{N} : |A| = |1 \ldots n| \\ A \text{ infinite} &:\Longleftrightarrow |\mathbb{N}| \leq |A| \\ A \text{ countable} &:\Longleftrightarrow |A| \leq |\mathbb{N}| \\ A \text{ countably infinite} &:\Longleftrightarrow |A| = |\mathbb{N}| \\ A \text{ uncountable} &:\Longleftrightarrow |\mathbb{N}| < |A| \end{aligned}$$

(0.35) Lemma: (viz. 698)

(i) $|\mathbb{N}| = |\mathbb{Z}|$

(ii) $|\mathbb{N}| = |\mathbb{N} \times \mathbb{N}|$

(iii) $|\mathbb{N}| = |\mathbb{Q}|$

(iv) If $\Omega \neq \emptyset$ is a non-empty, countable index set and for any $i \in \Omega$ we are given a countable set A_i, then the union of all the A_i is countable again

$$\bigcup_{i \in \Omega} A_i \text{ is countable}$$

Nota of course the same is true, if we replace the word *countable* with *finite*, as the number of elements in the union cannot exceed the sum of the number of elements of the A_i.

(v) If $X \neq \emptyset$ is any non-empty set, then there is no surjective map of the form $X \to \mathcal{P}(X)$, in particular

$$|X| \ < \ |\mathcal{P}(X)|$$

We are about to study the peculiar behaviour of infinite sets. Countable infinity is the smallest kind of infinity, but even this is so much more then finiteness. Infinity is so many, it's hard to grasp: E.g. give a number to each atom in the universe (well, this is to say the section of the universe, we are able to see). Then remove all these numbers from $\mathbb{N}$. What will you get? Much the same thing! Even after removing all these numbers from $\mathbb{N}$, the rest still is infinite. The whole universe fits inside $\mathbb{N}$ and it does not even reduce the space remaining in there! Infinity is just so amazingly large. And there even are sets containing more elements: For any set X the power set $\mathcal{P}(X)$ is larger. So there's no stop in creating new levels of infinity!
Time to clean up this mess a little: We will present different characterisations of infinite sets, but we chose not to give one long list, but rather several short lists, sorted thematically. While the lemma of Zorn will be a major asset in our argumentations, cardinal arguments are rare, so we recommend to look up the following theorems, when needed. There is no inherent benefit in working through the theory. We also need a few preparations, before we can tackle infinity:

(0.36) Proposition: (viz. 701)
Let $\mathcal{A} = \{ A_i \mid i \in I \}$ and $\mathcal{B} = \{ B_k \mid k \in K \}$ be arbitrary collections of sets, such that the elements of $\mathcal{A}$ resp. of $\mathcal{B}$ are pairwise distinct. That is we have the implications

$$\begin{aligned} \forall\, i,j \in I \;\; : \;\; i \neq j \;\; &\Longrightarrow \;\; A_i \cap A_j = \emptyset \\ \forall\, k,l \in K \;\; : \;\; k \neq l \;\; &\Longrightarrow \;\; B_k \cap B_l = \emptyset \end{aligned}$$

Also suppose $\beta : I \longleftrightarrow K$ is a bijective map, such that for any $i \in I$ we have $|A_i| = |B_{\beta(i)}|$. Then the grand union of the sets $\mathcal{A}$ and $\mathcal{B}$ are of the same size, too - formally

$$|\bigcup_{i\in I} A_i| \;\; = \;\; |\bigcup_{k\in K} B_k|$$

(0.37) Definition:
Let $\mathcal{A} = \{ A_i \mid i \in I \}$ be arbitrary collections of sets again, that is $I \neq \emptyset$ is an arbitrary index set and for any $i \in I$ we consider another set A_i. Then the **disjoint union** of the A_i guarantees, that the contributing sets are pairwise disjoint. That is we define

$$\bigsqcup_{i\in I} A_i \;\; := \;\; \bigcup_{i\in I} A_i'$$

where $A_i' := \{ i \} \times A_i = \{ (i, a_i) \mid a_i \in A_i \}$. Nota It is clear, that $|A_i'| = |A_i|$, as $(i, a_i) \mapsto a_i$ is bijective and that for any $i, j \in I$ with $i \neq j$ we get $A_i' \cap A_j' = \emptyset$. Hence the name disjoint union is well-chosen.

Nota If we use this construction on a collection $\mathcal{A}$ of sets, without obvious index set I, we can use $\mathcal{A}$ as an index set, itself. That is for any $A \in \mathcal{A}$ we let $A' := \{ A \} \times A = \{ (A, a) \mid a \in A \}$. If we had $(X, x) \in A' \cap B'$ then $(X, x) \in A'$ implies $X = A$ and likewise $(X, x) \in B'$ implies $X = B$ such that $A = B$. Thus A' and B' are either identical or disjoint.

(0.38) Proposition: (viz. 701)

(i) Let X be an infinite set, then there is a partition $\mathcal{P} \subseteq \mathcal{P}(X)$ in the sense of (0.12) of X, such that any $P \in \mathcal{P}$ is countably infinite.

(ii) If X is an infinite set and $n \in \mathbb{N}$ with $n \geq 1$, then we can partition X into n subsets of equal size. That is here are subsets $A_1, \ldots, A_n \subseteq X$ such that (1) for any $i, j \in 1 \ldots n$ with $i \neq j$ we get $A_i \cap A_j = \emptyset$, (2) $X = A_1 \cup \cdots \cup A_n$ and (3) for any $i \in 1 \ldots n$ we have $|A_i| = |X|$.

(iii) If $X \neq \emptyset$ is any non-empty set, then the following four statements are equivalent

(a) X is infinite
(b) for any finite set F we get $|X| = |X \cup F|$
(c) for any finite set F we get $|X| = |X \setminus F|$
(d) for any subset $A \subseteq X$ we get $|X| = |A \sqcup X|$

(iv) If X is any set with $\#X \geq 2$, then the following four statements are equivalent

(a) X is infinite
(b) $|X| = |X^2|$
(c) there is some $n \in \mathbb{N}$ with $n \geq 2$ and $|X| = |X^n|$
(d) for any $n \in \mathbb{N}$ with $n \geq 1$ we have $|X| = |X^n|$

(v) If $X \neq \emptyset$ is any non-empty set, then the following four statements are equivalent

(a) X is infinite
(b) $|X| = |X \times \mathbb{N}|$
(c) The set X is if the same size, as the set of all finite tuples over X, formally that is

$$|X| \quad = \quad |\bigcup_{n=1}^{\infty} X^n|$$

(d) Let us denote by $\Omega(X) := \{ A \subseteq X \mid A \text{ is finite} \}$ the set of finite subsets of X. Then X and $\Omega(X)$ are of the same size, that is

$$|X| \quad = \quad |\Omega(X)|$$

(vi) Let $X, Y \neq \emptyset$ be non-empty sets, such that at least one of them is infinite. Then both, the disjoint union $X \sqcup Y$ and the cartesian product $X \times Y$ has as many elements, as the larger set of X or Y

$$|X \sqcup Y| \quad = \quad |X \times Y| \quad = \quad \max\{ |X|, |Y| \}$$

(vii) Let $I \neq \emptyset$ and X be any infinite set, with $|I| \leq |X|$. Suppose that for any $i \in I$ we are given a countable set A_i, then the union of the A_i cannot contain more elements than X, that is

$$|\bigcup_{i \in I} A_i| \quad \leq \quad |X|$$

0.6 A Primer on Classes

Let us begin this section with a list of the different axioms of set theory in commented form, hoping that the interested reader can thereby get an idea how Cantor's notion can be formalized. At times this will require to give two formulations: One of naive set theory and the other in (almost) formal logic. Later on we will sketch how to extend these axioms to handle classes:

(0.39) Remark: (ZFC)

(1) *Axiom of Extensionality:* Using Cantor's notion of a set it is clear that any sets X and Y are equal, if and only if they contain the same elements. That is why we can prove $X = Y$ by proving $X \subseteq Y$ and $Y \subseteq X$ separately. The first axiom formalizes this property, its formula reads

$$\forall X \, \forall Y \, : \, X = Y \iff \forall a \, \big(a \in X \iff a \in Y \big)$$

(2) *Axiom of Union:* Given any collection of sets $\mathcal{A} = \{ A_i \mid i \in I \}$ we often use the *grand union* $A = \bigcup_i A_i$ of these sets. Then a is an element of A if and only if $a \in A_i$ for some $i \in I$. The following axiom guarantees, that the set A truly exists

$$\forall \mathcal{A} \, \exists A \, : \, \forall a \, \big(a \in A \iff \exists A_i \, : \, (A_i \in \mathcal{A} \text{ and } a \in A_i) \big)$$

(3) *Axiom of Power Set:* For any set X there is a set containing all the subsets of X. This is called the *power set* $\mathcal{P}(X) = \{ A \mid A \subseteq X \}$ of X. The following axiom guarantees that the power set truly exists

$$\forall X \, \exists \mathcal{P} \, : \, \forall A \, \big(A \in \mathcal{P} \iff A \subseteq X \big)$$

thereby the inclusion of sets $A \subseteq X$ is an abbreviation for another formula: $A \subseteq X$ is defined, as $\forall a \, (a \in A \implies a \in X)$. For those versed in formal logic: We enrich the language of sets by picking up $\subseteq$ as a relation symbol and define its meaning by this formula.

(4) *Scheme of the Axioms of Separation:* Given a set X and a *predicate* φ on X (this is a function $\varphi : X \to \{ \text{true}, \text{ false} \}$ of X we would like to pick up the set $\{ x \in X \mid \varphi(x) \}$ that consists of all the elements $x \in X$ such that $\varphi(x) = \text{true}$. For Cantor the existence of this set is evident, in formal set theory the purpose of the list of axioms is to pin down what we take for granted. Thus for every *predicate* φ we allow

$$\forall X \, \exists A \, : \, \forall x \, \big(x \in A \iff \big(x \in X \text{ and } \varphi(x) \big) \big)$$

So what is a predicate in the context of this scheme of axioms? Of course φ is a formula in the formal language of sets. And this formula has to contain x as a *free* variable, that is x is a variable symbol that is not bound by a quantifier $\forall$ or $\exists$ already (a notion that is best defined by recursion on the setup of the formula). For this scheme we require that x is the one and only free variable symbol of φ.

(5) *Axiom of Infinity:* It is possible to construct the natural numbers $\mathbb{N}$ in terms of set theory: We start with $0 := \emptyset$ and iteratively define $n+1$ to be the set $n \cup \{n\}$. Then $\mathbb{N}$ is the set containing 0, $1 = 0+1$, $2 = 1+1$ and so on and it can be shown that any other set N that is generated by a succession function $N \to N : n \mapsto n^+$ from a starting element has an order-preserving bijection to $\mathbb{N}$. In this sense the natural numbers are unique up to isomorphy. The natural numbers are such a basic notion, that nobody would doubt them, but in formal set theory we have to guarantee their existence by an axiom:

$$\exists N \left(\emptyset \in N \text{ and } \forall n \left(n \in N \implies n \cup \{n\} \in N\right)\right)$$

In order to break this formula down into the language of formal set theory we have to make several replacements: The empty set $\emptyset$ is defined by $E = \emptyset \iff \forall x (x \in \emptyset \iff x \neq x)$ Thus instead of $\emptyset \in N$ we would have to write $\exists E (E = \emptyset \text{ and } E \in N)$. The existence of $\emptyset$ is guaranteed by (4), just take the predicate $\varphi = (x \neq x)$. So it remains to define $n^+ = n \cup \{n\}$: Clearly $a \in n^+$ iff $a \in n$ or $a = n$. Thus we let $s = n^+ \iff \forall a (a \in n \text{ or } a = n)$. Therefore n^+ needs to be replaced by $\exists s (s = n^+ \text{ and } s \in N)$. The resulting formula is far too long to be captured in one line and hence we will abstain from providing it here.

(6) *Scheme of the Axioms of Replacement:* If $f : X \rightarrowtail Y$ is a partial function and $A \subseteq X$ is a subset of X, then we would like to map A (that is the part of A inside the domain of f) to Y. If $a \in A$ is mapped under f then the element $b = f(a) \in Y$ is uniquely determined. Therefore we will get a subset $B = f(A) = \{ f(a) \mid a \in A \cap \mathrm{dom}(f) \} \subseteq Y$. Let us make the existence of $f(A)$ an axiom:

$$\forall f \left(f : X \rightarrowtail Y \implies \forall A \exists B \forall b \left(b \in B \iff b \in f(A)\right)\right)$$

$$\text{where} \quad b \in f(A) \quad :\iff \quad \exists a \left(a \in A \text{ and } b = f(a)\right)$$

It requires some effort to formulate this in the language of sets. First of all we have to replace the partial function f: Let φ be a formula in the language of sets having the the free variables x and y [refer to (4) for this]. If now a and b are any variable symbols, then $\varphi(x : a, y : b)$ denotes the formula where every free occurrence of x is replaced by a and any free occurence of y is replaced by b. We now recall how we introduced functions as sets: We defined $b = f(a)$ by afb. Thus we replace $b = f(a)$ by $\varphi(x : a, y : b)$. Consequently $f : X \rightarrowtail Y$ has to be replaced by

$$\forall a \forall b_1 \forall b_2 \left(\left(\varphi(x : a, y : b_1) \text{ and } \varphi(x : a, y : b_2)\right) \implies b_1 = b_2\right)$$

It remains to replace the quantifier $\forall f$, as we replaced f by a formula φ. Hence we take this formula as an axiom for every formula φ that has the free variables x, y and $s_1, \ldots, s_n$ ($n \in \mathbb{N}$) but no others. Then we replace $\forall f$ by $\forall s_1 \ldots \forall s_n$ and are finally done.

(7) *Axiom of Foundation:* Cantor would say that no set can satisfy $X \in X$, by the following reasoning: In order to build up the set X we need to know all its elements. So X cannot be on of its own elements, since by the time we think of the set X the element X is incomplete. For the same reason there can be no circle of sets $X_1 \in X_2$, $X_2 \in X_3$ and so on $X_{n-1} \in X_n$ with $X_n \in X_1$ again.

In formal set theory one usually takes a little stronger property to be an axiom: Every non-empty set X contains an element d, that is disjoint to X, as a formula:

$$\forall X \left(X \neq \emptyset \implies \exists d \left(d \in X \text{ and } d \cap X = \emptyset \right) \right)$$

In the formal language we only have to make little adjustments: $X \neq \emptyset$ needs to be reformulated as $\exists u\, u \in X$ and $d \cap X = \emptyset$ has to be replaced by $\forall v \left(v \in x \text{ and } v \in X \implies v \neq v \right)$. It is easy to deduce the non-existence of circles from this axiom (see below). And using the axiom of choice we can also deduct this formula from the non-existence of circles of sets.

Prob Suppose we had a circle of sets $x_1, \ldots, x_n$ such that $x_k \in x_{k+1}$ and $x_n \in x_1$. Then we consider $X := \{ x_1, \ldots, x_n \}$ and choose some $d \in X$ such that $d \cap X = \emptyset$. By construction we have $d = x_k$ for some $k \in 1 \ldots n$. Thus $x_{k-1} \in d$ or $x_n \in d$ for $k = 1$. That is $x_i \in d$ for some $i \in 1 \ldots n$. But then $x_i \in d \cap X$ in contradiction to $d \cap X = \emptyset$.

(8) *Axiom of Choice:* This has often been stated: Given an arbitrary collection of sets $\mathcal{A} = \{ A_i \mid i \in I \}$ such that $A_i \neq \emptyset$ is non-empty (for any $i \in I$) there is a set $A = \{ a_i \mid i \in I \}$ such that for any $i \in I$ the element a_i is taken from $a_i \in A_i$. We say that A is a *choice from* $\mathcal{A}$.

In fact it suffices to claim a little less: If $\mathcal{P}$ is a partition of some set X then there is a set $A \subseteq X$ such that for any $a \in A$ there is exactly one $P \in \mathcal{P}$ such that $a \in P$ (see below). We will now formalize this property as an axiom:

$$\forall \mathcal{P} \left(\mathcal{P} \text{ partition} \implies \exists A \ : A \text{ choice from } \mathcal{P} \right)$$

Hereby "$\mathcal{P}$ partition" abbreviates a formula in the language of sets, namely $\emptyset \notin \mathcal{P}$ and $(\forall P \forall Q \ldots)$ where $\ldots$ is given to be the following formula

$$P \in \mathcal{P} \text{ and } Q \in \mathcal{P} \text{ and } \exists x \left(x \in P \text{ and } x \in Q \right) \implies P = Q$$

And likewise "A choice from $\mathcal{P}$" abbreviates another formula, this time the abbreviated formula is

$$\forall P \left(P \in \mathcal{P} \implies \exists!\, a \left(a \in A \text{ and } a \in P \right) \right)$$

Prob Let us define $P_i := \{ i \} \times A_i$ and $X := \bigcup P_i$ Then it is clear that $\mathcal{P} := \{ P_i \mid i \in I \}$ is a partition of X. Thus there is some $P \subseteq X$ such that for any $p \in P$ there is a unique $P_i \in \mathcal{P}$ with $p \in P_i$. By construction p is of the form $p = (i, a)$ for some $a \in A_i$. Now define $\pi : X \to \bigcup_i A_i$ by $(i, a) \mapsto a$. Then $A := \pi(P)$ is a choice from $\mathcal{A}$.

Intuitively speaking classes are collections of sets that are just too large to be a set themselves. E.g. if we denote $\mathcal{U}$ the collection of *all* sets (sometimes also called the *universe*) and would think that this could be a set, then we would have $\mathcal{U} \in \mathcal{U}$, which we shun. As we wish to address such constructions, we need a new term for these, in order to avoid contradictions. This new term is **class**, that's all. In fact there are classes, that can well be sets, these classes are called *small*, but the interesting classes are not.

Warning: The rest of this section will advance set-theory by introducing classes, as a second, fundamental concept. This will definitely not be needed prior to chapter 11 where we proceed on to categorial algebra. And even there, a naive understanding of classed is all that is required. Do not venture on with this section, unless you have a solid working knowledge of set theory and feel comfortable with the axioms of ZFC. And if you are interested in standard algebra only, skip this section entirely. You will *not* miss a single thing.

From a formal point of view we extend the language of sets (with only one sort of variable symbols, which we interpret as sets) to a language of sets and classes (with two sorts of variable symbols, one for sets and one for classes). Most textbooks try to avoid this by introducing two predicate symbols one saying *I am a set* and the other saying *I am a class*, but accepting the two sorts is the natural way to go. Thus in this two-sorted language we will have separate quantifiers for the different sorts:

	universal quantifier	existential quantifier
sets	$\forall_s$	$\exists_s$
classes	$\forall_c$	$\exists_c$

For example the formula $\forall_s X \, \exists_c \mathcal{C} : X = \mathcal{C}$ says: For every set X there is a class $\mathcal{C}$ that is equal to X. This will even be the first of our axioms for classes. So here comes the rest: A commented list of (NBG) !! NBG axioms !!

Chapter 1

Groups and Rings

1.1 Defining Groups

The most familiar (and hence easiest to understand) objects of algebra are rings. And of these the easiest example are the integers $\mathbb{Z}$. On these there are two operations: an addition $+$ and a multiplication $\cdot$. Both of these operations have familiar properties (associativity for example). So we first study objects with a single operation $\circ$ only - monoids and groups - as these are a unifying concept for both addition and multiplication. However our aim solely lies in preparing the concepts of rings and modules, so the reader is asked to venture lightly over problems within this section until he has reached the later sections of this chapter.

(1.1) Definition:
Let $G \neq \emptyset$ be any non-empty set and $\circ$ a *binary operation* on G, i.e. $\circ$ is a mapping of the form $\circ : G \times G \to G : (x,y) \mapsto xy$. Then the ordered pair $(G,\circ)$ is said to be a **monoid** iff it satisfies the following properties

(A) $\forall\, x,y,z \in G \;:\; x(yz) \;=\; (xy)z$

(N) $\exists\, e \in G \;\; \forall\, x \in G \;:\; xe \;=\; x \;=\; ex$

Note that this element $e \in G$ whose existence is required in (N) then already is uniquely determined (see below). It is said to be the **neutral element** of G. And therefore we may define: A monoid $(G,\circ)$ is said to be a **group** iff any element $x \in G$ has an **inverse element** $y \in G$, that is iff

(I) $\forall\, x \in G \;\; \exists\, y \in G \;:\; xy \;=\; e \;=\; yx$

Note that in this case the inverse element y of x is uniquely determined (see below) and we hence write $x^{-1} := y$. Finally a monoid (or group) $(G,\circ)$ is said to be **commutative** iff it satisfies the property

(C) $\forall\, x,y \in G \;:\; xy \;=\; yx$

(1.2) Remark:

- We have to append some remarks here: First of all we have employed a function $\circ : G \times G \to G$. The image $\circ(x,y)$ of the pair $(x,y) \in G \times G$ has been written in an unfamiliar way however

$$xy \;:=\; \circ(x,y)$$

If you have never seen this notation before it may be somewhat startling, in this case we would like to reassure you, that this actually is nothing new - just have a look at the examples further below. Yet this notation has the advantage of restricting itself to the essential. If we had stuck to the classical notation such terms would be by far more obfuscated. E.g. let us rewrite property (A) in classical terms

$$\circ\Big(x, \circ(y,z)\Big) \;=\; \circ\Big(\circ(x,y), z\Big)$$

- It is easy to see that the neutral element e of a monoid $(G,\circ)$ is uniquely determined: Suppose that another element $f \in G$ would satisfy $\forall\, x \in G : xf = x = fx$, then we would have $ef = e$ by letting $x = e$. But as e is a neutral element we have $ef = f$ by (N) applied with $x = f$. And hence $e = f$ are equal, i.e. e is uniquely determined. Hence in the following we will reserve the letter e for the neutral element of the monoid regarded *without specifically mentioning it*. In case we apply several monoids at once, we will name the respective neutral elements explicitly.

- Property (A) is a very important one and hence it has a name of its own: **associativity**. A pair $(G,\circ)$ that satisfies (A) only also is called a **groupoid**. We will rarely employ these objects however.

- Suppose $(G,\circ)$ is a monoid with the (uniquely determined) neutral element $e \in G$. And suppose $x \in G$ is some element of G, that has an inverse element. Then this inverse is uniquely determined: Suppose both y and $z \in G$ satisfy $xy = e = yx$ and $xz = e = zx$. Then the asociativity yields $y = z$, as we may compute

$$y \;=\; ye \;=\; y(xz) \;=\; (yx)z \;=\; ez \;=\; z$$

- Another important consequence of the associativity is the following: Consider finitely many elements $x_1, \ldots, x_n \in G$ (where $(G,\circ)$ is a groupoid at least). Then any application of parentheses to the product $x_1x_2\ldots x_n$ produces the same element of G. As an example consider

$$x_1(x_2(x_3x_4)) \;=\; x_1((x_2x_3)x_4) \;=\; (x_1(x_2x_3))x_4 \;=\; ((x_1x_2)x_3)x_4$$

 In every step of these equalities we have only used the associativity law (A). The remarkable fact is that *any* product of *any* n elements (here $n = 4$) only depends on the order of the elements, not on the bracketing. Hence it is costumary to omit the bracketing altogether

$$x_1x_2\ldots x_n \;:=\; \Big((x_1x_2)\ldots\Big)x_n \;\in\; G$$

 And any other assignment of pairs (without changing the order) to the elements x_i would yield the same element as $x_1x_2\ldots x_n$. A formal version of this statement and its proof are given in section 15.2 of this book. The proof clearly will be done by induction on $n \geq 3$, the foundation of the induction precisely is the law of associativity.

- Suppose $(G,\circ)$ is any groupoid, $x \in G$ is an element and $1 \leq k \in \mathbb{N}$, then we abbreviate the k-nary product of x by x^k, i.e. we let

$$x^k \;:=\; xx\ldots x \quad (k - \text{times})$$

If $(G, \circ)$ even is a monoid (with neutral element e) it is customary to define $x^0 := e$. Thus in this case $x^k \in G$ is defined for all $k \in \mathbb{N}$. Now suppose that x even is invertible (e.g. if $(G, \circ)$ is a group), then we may even define $x^k \in G$ for any $k \in \mathbb{Z}$. Suppose $1 \leq k \in \mathbb{N}$, then

$$x^{-k} \;:=\; \left(x^{-1}\right)^k$$

- In a commutative groupoid $(G, \circ)$ we may even change the order in which the $x_1, \ldots, x_n \in G$ are multiplied. I.e. if we are given a bijective map $\sigma : 1 \ldots n \longleftrightarrow 1 \ldots n$ on the indexes $1 \ldots n$ we get

$$x_{\sigma(1)} x_{\sigma(2)} \ldots x_{\sigma(n)} \;=\; x_1 x_2 \ldots x_n$$

 The reason behind this is the following: Any permutation σ can be decomposed into a series of transpositions (this is intuitively clear: We can generate any order of n objects by repeatedly interchanging two of these objects). In fact any transposition can be realized by interchanging adjacent objects only. But any transposition of adjacent elements is allowed by property (C). A formal proof of this reasoning will be presented in section 15.2 again.

(1.3) Example:

- The most familiar example of a (commutative) monoid are the natural numbers under addition: $(\mathbb{N}, +)$. Here the neutral element is given to be $e = 0$. However $1 \in \mathbb{N}$ has no inverse element (as for any $a \in \mathbb{N}$ we have $a + 1 > 0$) and hence $(\mathbb{N}, +)$ is no group.

- The integers however are a (commutative) group $(\mathbb{Z}, +)$ under addition. The neutral element is zero again $e = 0$ and the inverse element of $a \in \mathbb{Z}$ is $-a$. Thus $\mathbb{N}$ is contained in a group $\mathbb{N} \subseteq \mathbb{Z}$.

- Next we regard the non-zero rational numbers $\mathbb{Q}^* := \{\, a/b \mid 0 \neq a, b \in \mathbb{Z} \,\}$. These form a group under multiplication $(\mathbb{Q}^*, \cdot)$. The neutral element is given to be $e = 1/1$ and the inverse of some $a/b \in \mathbb{Q}^*$ is its sweep break $(a/b)^{-1} = b/a$.

- Consider any non-empty set $X \neq \emptyset$. Then the set of maps from X to X, which (as always) we denote by $\mathcal{F}(X) := \{\, \sigma \mid \sigma : X \to X \,\}$, becomes a monoid under the composition of maps $(\mathcal{F}(X), \circ)$ (as the composition of functions is associative). The neutral element is the identity map $e = \mathbb{1}_X$ which is given to be $\mathbb{1}_X : x \mapsto x$.

- Consider any non-empty set $X \neq \emptyset$ again. Then $S_X := \{\, \sigma : X \to X \mid \sigma \text{ bijective} \,\} \subseteq \mathcal{F}(X)$ the set of bijective maps on X even becomes a group under the composition of maps $(S_X, \circ)$. The neutral element is the identity map $e = \mathbb{1}_X$ again and the inverse of $\sigma \in S_X$ is the inverse function σ^{-1}. This will be continued in the next section.

- $(\diamondsuit)$ A special case of the above is $\mathrm{gl}_n(E) := \{\, A \in \mathrm{mat}_n(E) \mid \det(A) \neq 0 \,\}$ the set of invertible $(n \times n)$-matrices over a field $(E, +, \cdot)$. This is a group $(\mathrm{gl}_n(E), \cdot)$ under the multiplication $\cdot$ of matrices. Symmetries in E^n are subgroups of $\mathrm{gl}_n(E)$ and representation theory will be concerned with regarding *any* group G as some subgroup of $\mathrm{gl}_n(E)$.

(1.4) Remark:
Consider a finite groupoid $(G, \circ)$, that is the set $G = \{ x_1, \ldots, x_n \}$ is finite. Then the composition $\circ$ can be given by a table of the following form

$\circ$	x_1	x_2	$\ldots$	x_n
x_1	x_1x_1	x_1x_2	$\ldots$	x_1x_n
x_2	x_2x_1	x_2x_2	$\ldots$	x_2x_n
$\vdots$	$\vdots$	$\vdots$		$\vdots$
x_n	x_nx_1	x_nx_2	$\ldots$	x_nx_n

Such a table is also known as the **Cayley diagram** of G. As an example consider a set with 4 elements $K := \{ e, x, y, z \}$, then the following diagram determines a group structure $\circ$ on K [what we do not want to prove here, but you can easily see, that K is commutative and $k^2 = e$ and hence $k^{-1} = k$ for any $k \in K$]. This group $(K, \circ)$ is called the *Klein 4-group*.

$\circ$	e	x	y	z
e	e	x	y	z
x	x	e	z	y
y	y	z	e	x
z	z	y	x	e

(1.5) Proposition: (viz. 710)
Let $(G, \circ)$ be any group (with neutral element e), x, $y \in G$ be any two elements of G and k, $l \in \mathbb{Z}$. Then we obtain the following identities

$$\begin{aligned} e^{-1} &= e \\ \left(x^{-1}\right)^{-1} &= x \\ \left(xy\right)^{-1} &= y^{-1}x^{-1} \\ x^k x^l &= x^{k+l} \\ \left(x^k\right)^l &= x^{kl} \end{aligned}$$

In particular the inversion $i : G \longleftrightarrow G : x \mapsto x^{-1}$ of elements is a self-inverse, bijective mapping $i = i^{-1}$ on the group G. If now $xy = yx$ do commute then for any $k \in \mathbb{Z}$ we also obtain

$$xy = yx \quad \Longrightarrow \quad (xy)^k = x^k y^k$$

(1.6) Definition:
If $(G, \circ)$ and $(H, \circ)$ are any two groups, whose neutral elements are $e \in G$ and $f \in H$ respectively, then a map $\varphi : G \to H$ is said to be a **homomorphism of groups** or *group-homomorphism*, iff it satisfies

$$\forall\, x, y \in G \quad \text{we get} \quad \varphi(xy) \;=\; \varphi(x)\varphi(y)$$

And in this case φ already links the neutral elements and maps inverse elements to the inverse, that is it satisfies $\varphi(e) = f$ and [the proof will be given shortly]

$$\forall\, x \in G \quad \text{we get} \quad \varphi(x^{-1}) \;=\; \varphi(x)^{-1}$$

Let us introduce the set of all group-homomorphisms from G to H, which we will denote as

$$\mathrm{ghom}(G,H) \;:=\; \{\, \varphi : G \to H \mid \forall\, x,y \in G : \varphi(xy) = \varphi(x)\varphi(y) \,\}$$

Prob clearly $\varphi(e) = \varphi(ee) = \varphi(e)\varphi(e)$ but as H is a group we may multiply by $\varphi(e)^{-1}$ to find $f = \varphi(e)$. Therefore we have $f = \varphi(e) = \varphi(xx^{-1}) = \varphi(x)\varphi(x^{-1})$. And likewise we get $f = \varphi(x^{-1})\varphi(x)$ and hence $\varphi(x^{-1}) = \varphi(x)^{-1}$ as we had claimed before.

(1.7) Proposition: (viz. 712)
Let $(G,\circ)$ be a group with neutral element $e \in G$, then a subset $P \subseteq G$ is said to be a **subgroup** of G (written as $P \leq_{\mathrm{g}} G$) iff it satisfies

$$\begin{aligned} e \quad &\in \quad P \\ x,y \in P \quad &\Longrightarrow \quad xy \in P \\ x \in P \quad &\Longrightarrow \quad x^{-1} \in P \end{aligned}$$

In other words $P \subseteq G$ is a subgroup of G iff it is a group $(P,\circ)$ under the operation $\circ$ inherited from G. And in this case we obtain an equivalence relation on G by letting (for any x, $y \in G$)

$$x \sim y \quad :\Longleftrightarrow \quad y^{-1}x \in P$$

And for any $x \in G$ the equivalence class of x is thereby given to be the **coset** $xP := [x] = \{\, xp \mid p \in P \,\}$. We thereby define the **index** $[G : P]$ of P in G to be the following cardinal number

$$\begin{aligned} G\big/_P \;&:=\; G\big/_\sim \\ [\,G : P\,] \;&:=\; \left|G\big/_P\right| \end{aligned}$$

And thereby we finally obtain the following identity of cardinals which is called the *Theorem of Lagrange* (and which means, that there is a bijective map $G \longleftrightarrow (G/P) \times P$)

$$|G| \;=\; [\,G : P\,] \cdot |P|$$

(1.8) Proposition: (viz. 712)
Let $(G,\circ)$ be any monoid with neutral element e and $X \subseteq G$ be any subset of G. Then the intersection of all submonoids of G that contain X is a submonoid of G again

$$\langle X \rangle_{\mathrm{o}} \;:=\; \bigcap \{\, P \leq_{\mathrm{o}} G \mid X \subseteq P \,\} \quad \leq_{\mathrm{o}} \quad G$$

We call $\langle X \rangle_o$ the monoid **generated** by $X \subseteq G$. And letting $X_e := X \cup \{ e \}$ we can even give an explicit description of $\langle X \rangle_o$ to be the following set

$$\langle X \rangle_o \quad = \quad \{ x_1 x_2 \dots x_n \mid n \in \mathbb{N},\, x_1, \dots, x_n \in X_e \}$$

If G even is a group, then we can regard the intersection of all subgroups of G that contain X and this is a subgroup of X again

$$\langle X \rangle_g \quad := \quad \bigcap \{ P \leq_o G \mid X \subseteq P \} \quad \leq_g \quad G$$

Likewise we call $\langle X \rangle_g$ the group **generated** by $X \subseteq G$. And letting $X_\pm := X \cup \{ e \} \cup \{ x^{-1} \mid x \in X \}$ we can even give an explicit description of $\langle X \rangle_g$ to be the following set

$$\langle X \rangle_g \quad = \quad \{ x_1 x_2 \dots x_n \mid n \in \mathbb{N},\, x_1, \dots, x_n \in X_\pm \}$$

(1.9) Proposition: (viz. 713)
If $(G, \circ)$ is a group and $x \in G$ is any element of G, then the above proposition tells us that the subgroup generated by x is given to be

$$\langle x \rangle_g \quad = \quad \left\{ x^k \mid k \in \mathbb{Z} \right\}$$

If now G is *finite*, that is $n := \#G \in \mathbb{N}$, then $\langle x \rangle_g$ (being a subset) is finite too. In particular we may define the **order** of x to be number of elements of $\langle x \rangle_g$. And thereby we find

$$\operatorname{ord}(x) \quad := \quad \#\langle x \rangle_g \quad = \quad \min \left\{ 1 \leq k \in \mathbb{N} \mid x^k = e \right\}$$

That is $k = \operatorname{ord}(x)$ is the *minimal* number $1 \leq k \in \mathbb{N}$ such that $x^k = e$ and this k divides n. That is for a finite group G and any element $x \in G$ we will always have

$$\operatorname{ord}(x) \quad | \quad \#G$$

And from this we conclude another *theorem of Lagrange:* In particular, if G is finite, containing $n := \#G$ elements, then any element $x \in G$ satisfies $x^n = e$, formally we get

$$x^{\#G} \quad = \quad e$$

1.2 Permutations

In this section we will study the most important and most general example of groups: permutations. Permutation groups will not become important until we reach determinants in chapter 4. So a novice might well skip the entire section and return to it only later. In fact we even recommend this approach, as we deem the basics of ring theory to be easier to understand, than the basics of group theory. Also we will use some notation (namely products and the faculty) that will only be introduced in sections 1.3 and 1.5 respectively.
Later in section 9.2 we will introduce group actions, that are a generalization of the permutation action. Also permutations are used to study conjugation in a group and they are occasionally useful in other areas as well. In fact they will be applied in Galois, representation and invariant theory.

(1.10) Definition: (viz. 714)
If $X \neq \emptyset$ is any non-empty set then we define the group S_X of **permutations** of X to be the set of all bijective maps on X, that is

$$S_X \;:=\; \{\, \sigma : X \to X \mid \sigma \text{ is bijective} \,\}$$

Thereby S_X truly becomes a group $(S_X, \circ)$ under usual the composition $\circ$ of functions. An in case of $X = 1 \ldots n$ we will write

$$S_n \;:=\; \{\, \sigma : (1 \ldots n) \to (1 \ldots n) \mid \sigma \text{ is bijective} \,\}$$

(1.11) Remark:
If $\emptyset \neq X \subseteq Y$ is a non-empty subset of some set Y, then it is clear that the permutations on X can be regarded as a subset of the permutations on Y. That is we get the following monomorphism of groups:

$$S_X \hookrightarrow S_Y \;:\; \pi \mapsto \overline{\pi}$$

where $\overline{\pi} : Y \to Y$ is defined by $\overline{\pi}(x) := \pi(x)$ for any $x \in X$ and $\overline{\pi}(y) := y$ for any $y \in Y \setminus X$. The image if this monomorphism is just the set of all $\sigma \in S_Y$ that fix all the elements of $Y \setminus X$, formally again:

$$S_X \longleftrightarrow \{\, \sigma \in S_Y \mid \forall\, y \in Y \setminus X : \sigma(y) = y \,\}$$

(1.12) Proposition: (viz. 714)

(i) If X is a finite set, $n := \#X \in \mathbb{N}$then the group $(S_X, \circ)$ is finite again, in fact it contains precisely $n!$ elements, formally that is

$$\#S_X \;=\; (\#X)!$$

(ii) Fix any $1 \leq n \in \mathbb{N}$ and [the set $X := 1 \ldots (n+1)$] and denote the subgroup of all permutations $\sigma \in S_{n+1} = S_X$ that fix $n+1$ by

$$S'_n \;:=\; \{\, \sigma \in S_{n+1} \mid \sigma(n+1) = n+1 \,\}$$

And for any $k \in 1 \ldots (n+1)$ denote $\tau_k := (k\ n+1)$ the *transposition* of k and $n+1$, i.e. the permutation that only interchanges these two numbers. Then we will prove that the following subsets of S_{n+1} are identical

$$\begin{aligned} \tau_k S'_n &:= \{\, \tau_k \pi \mid \pi \in S'_n \,\} \\ &= \{\, \sigma \in S_{n+1} \mid \sigma(n+1) = k \,\} \end{aligned}$$

And thereby S_{n+1} can be written as the following disjoint union (*disjoint* is to say, that for any $i \neq j \in 1 \ldots (n+1)$ we have $\tau_i S'_n \cap \tau_j S'_n = \emptyset$)

$$S_{n+1} := \bigcup_{k=1}^{n+1} \tau_k S'_n$$

(iii) If $(G, \circ)$ is any group, then G can be embedded into $(S_G, \circ)$. To be precise the following map is well-defined and injective

$$L : G \hookrightarrow S_G : g \mapsto L_g$$

$$L_g : G \to G : x \mapsto gx$$

and a homomorphism of groups, that is: $L_e = \mathbb{1}_G$ and for any $g, h \in G$ we get $L_{gh} = L_g L_h$. NOTA in this sense the permutation groups S_X are the most general groups whatsoever.

(1.13) Definition:
Fix a non-empty set $X \neq \emptyset$ and consider the permutation group $(S_X, \circ)$. For any permutation $\sigma \in S_X$ and any $x \in X$, we define the **fixed point** set $\mathrm{fix}(\sigma)$ of σ and its complement $\mathrm{dom}(\sigma)$ is called the **domain** of σ. Also $\mathrm{cyc}(\sigma, x)$ is called the **cycle** of x under σ and $\ell(\sigma, x)$ is said to be the **length** of that cycle.

$$\begin{aligned} \mathrm{fix}(\sigma) &:= \{\, x \in X \mid \sigma(x) = x \,\} \\ \mathrm{dom}(\sigma) &:= \{\, x \in X \mid \sigma(x) \neq x \,\} \\ \mathrm{cyc}(\sigma, x) &:= \left\{\, \sigma^k(x) \mid k \in \mathbb{N} \,\right\} \\ \ell(\sigma, x) &:= \#\,\mathrm{cyc}(\sigma, x) \end{aligned}$$

(1.14) Proposition: (viz. 715)
Fix a non-empty set $X \neq \emptyset$ and consider the permutation group $(S_X, \circ)$. Then, for any permutations ϱ and $\sigma \in S_X$ and any $x \in X$ we find the following statements

(i) If $n := \#X < \infty$ is finite, then the length $\ell(\sigma, x)$ if finite, too. More precisely the length of the cycle of x under σ cannot exceed the order of σ, and therefore

$$\ell(\sigma, x) \;\leq\; \mathrm{ord}(\sigma) \;\leq\; n!$$

(ii) The fixed points and domain of σ are stable under σ. That is for any $x \in \mathrm{fix}(\sigma)$ we find $\sigma(x) \in \mathrm{fix}(\sigma)$ again. Likewise for any $x \in \mathrm{dom}(\sigma)$ we find $\sigma(x) \in \mathrm{dom}(\sigma)$. In fact we even find

$$\sigma\big(\mathrm{fix}(\sigma)\big) \;=\; \mathrm{dom}(\sigma)$$

$$\sigma\big(\mathrm{dom}(\sigma)\big) \;=\; \mathrm{dom}(\sigma)$$

In particular, if $x \in \mathrm{dom}(\sigma)$ is contained in the domain of σ, then $\sigma^k(x)$ is contained in the domain of σ, for any power $k \in \mathbb{N}$, such the entire cycle of x is contained in the domain of σ

$$\mathrm{cyc}(\sigma, x) \;\subseteq\; \mathrm{dom}(\sigma)$$

(iii) If ϱ and σ share a common domain $D \subseteq X$ and agree on D, then they already are equal. Formally that is the following equivalence of

$$\left.\begin{array}{l} D := \mathrm{dom}(\varrho) = \mathrm{dom}(\sigma) \\ \forall\, x \in D \;:\; \varrho(x) = \sigma(x) \end{array}\right\} \quad\Longleftrightarrow\quad \varrho \;=\; \sigma$$

(iv) If the domains of ϱ and σ are disjoint, then ϱ and σ commute. That is we have the implication

$$\mathrm{dom}(\varrho) \cap \mathrm{dom}(\sigma) \;=\; \emptyset \quad\Longrightarrow\quad \varrho\sigma \;=\; \sigma\varrho$$

(1.15) Definition:
Fix $n \in \mathbb{N}$ with $n \geq 1$ and consider an ℓ-tuple $(i_1, \ldots, i_\ell)$ of natural numbers $i_k \in 1 \ldots n$ that are pariwise distinct (that is $i_j = i_k \implies j = k$). Then the tuple $(i_1, \ldots, i_\ell)$ gives rise to a permutation $\zeta \in S_n$ by

$$\zeta(a) \;:=\; \begin{cases} a \text{ if } a \in (1 \ldots n) \setminus \{\, i_1, \ldots, i_\ell \,\} \\ i_{k+1} \text{ if } a = i_k \text{ for some } k \in 1 \ldots \ell - 1 \\ i_1 \text{ if } a = i_\ell \end{cases}$$

This permutation $\zeta \in S_n$ is called a **cycle** of **length** ℓ and (by slight abuse of notation, as n is not specified) we will denote this cycle by the symbol

$$(i_1\; i_2\; \ldots\; i_\ell) \;:=\; \zeta$$

A cycle of length 2 is said to be a **transposition** of S_n. And by definition it interchanges two numbers $i \neq j$. That is, if $\tau = (i\; j)$ then $\tau(i) = j$ and $\tau(j) = i$ and $\tau(a) = a$ for any other $a \in 1 \ldots n$.

(1.16) Remark: (viz. 716)

- The notation of cycles is ambigious as it is of no effect with which element the cycle starts, as long as the ordering of elements is not changed. That is $(i_1\; i_2\; \ldots\; i_\ell)$ and $(i_2\; i_3\; \ldots\; i_\ell\; i_1)$ and so on until $(i_\ell\; i_1\; i_2\; \ldots\; i_{\ell-1})$ all yield the same permutation. In particular we have $(i\; j) = (j\; i)$ for any transposition.

- Any cycle ζ can be written as a composition of transpositions. Let us be explicit: Given the cycle $(i_1\ i_2\ \ldots\ i_\ell)$ we can rewrite this one, in the following form

$$(i_1\ i_2\ \ldots\ i_\ell) \quad = \quad (i_1\ i_\ell)(i_1\ i_{\ell-1})\ldots(i_1\ i_2)$$

- Any transposition can be written as a composition of transpositions of adjacent elements. To be precise given any $i, j \in 1\ldots n$ with $i < j$ we can rewrite

$$(i\ \ j) \ = \ (i\ \ i+1)(i+1\ \ i+2)\ldots(j-1\ \ j)(j-2\ \ j-1)\ldots(i\ \ i+1)$$

- If $\zeta = (i_1\ i_2\ \ldots\ i_\ell) \in S_n$ is a cycle of length ℓ, then for any other permutation $\sigma \in S_n$ the conjugate $\sigma\zeta\sigma^{-1}$ is another cycle of length ℓ. In fact we get

$$\sigma\zeta\sigma^{-1} \quad = \quad (\sigma(i_1)\ \ \sigma(i_2)\ \ \ldots\ \ \sigma(i_\ell))$$

(1.17) Proposition: (viz. 717)
Fix $n \in \mathbb{N}$ with $n \geq 1$ and consider the perumtation group $(S_n, \circ)$. If now $\sigma \in S_n$ is any permutation with $\sigma \neq \mathbb{1}$ then the following five statements are equivalent:

(a) σ is a **cycle**, that is there are some $\ell \geq 2$ and some pairwise distinct $i_1, i_2, \ldots, i_\ell \in 1\ldots n$ [which is to say is $i_j = i_k \implies j = k$] such that

$$\sigma \quad = \quad (i_1\ i_2\ \ldots\ i_\ell)$$

(b) Any two elements $a, b \in \mathrm{dom}(\sigma)$ in the domain of σ are linked in the following sense: There is some $k \in \mathbb{N}$ such that $b = \sigma^k(a)$.

(c) For any element $i \in \mathrm{dom}(\sigma)$ the domain of σ already is generated by the orbit of i under σ, that is

$$\mathrm{dom}(\sigma) \quad = \quad \left\{ \sigma^k(i) \mid k \in \mathbb{N} \right\}$$

(d) There is some $i \in 1\ldots n$ such that the domain of σ is the orbit of i under σ. That is the identity of

$$\mathrm{dom}(\sigma) \quad = \quad \left\{ \sigma^k(i) \mid k \in \mathbb{N} \right\}$$

(e) If $\ell := \mathrm{ord}(\sigma)$ denotes the order of σ, then there is some $i \in 1\ldots n$ such that the domain of σ is

$$\mathrm{dom}(\sigma) \quad = \quad \left\{ \sigma^k(i) \mid k \in 0\ldots(\ell-1) \right\}$$

And in this case the length ℓ of the cycle $\sigma = (i_1\ i_2\ \ldots\ i_\ell)$ is precisely the order of σ. That is the index ℓ in (a) equals the order of σ as an element of S_n

$$\mathrm{ord}(\sigma) \quad = \quad \ell \quad \text{in (a)}$$

(1.18) Proposition: (viz. 718)
Fix $n \in \mathbb{N}$ with $n \geq 1$ and consider the permutation group $(S_n, \circ)$. Remember that a *cycle* is special permutation $\sigma \in S_n$ that satisfies any of the equivalent properties in (1.17). Then, for permutation $\sigma \in S_n$ and any $i \in 1 \dots n$, we find the following statements

(i) We obtain an equivalence relation on $1 \dots n$ by letting $i \sim j$ if and only if there is some $k \in \mathbb{N}$ such that $j = \sigma^k(i)$. And the equivalence classes under this relation are precisely

$$[i] \;=\; \mathrm{cyc}(\sigma, i) \;=\; \Big\{ i, \sigma(i), \dots, \sigma^{k(i)}(i) \Big\}$$

where $k(i) := \ell(\sigma, i) - 1$. In particular $\mathrm{cyc}(\sigma, i)$ is σ-invariant: That is $\mathrm{cyc}(\sigma, i)$ remains fixed under σ, which formally reads as $\sigma(\mathrm{cyc}(\sigma, i)) = \mathrm{cyc}(\sigma, i)$. Let us now regard

$$\zeta_i \;:\; 1 \dots n \to 1 \dots n \; \begin{cases} \sigma(a) \text{ if } a \in \mathrm{cyc}(\sigma, i) \\ \quad a \text{ if } a \notin \mathrm{cyc}(\sigma, i) \end{cases}$$

That is ζ_i acts as σ on the cycle $\mathrm{cyc}(\sigma, i)$ but acts as the identity outside this cycle. Then ζ_i is precisely the cycle induced by σ on $i \in 1 \dots n$, formally again

$$\zeta_i \;=\; (i\ \sigma(i)\ \dots\ \sigma^{k(i)}(i))$$

And if $i(1), \dots, i(r)$ is a system of representative of $\mathrm{dom}(\sigma)$ under the relation $\sim$, that is $\mathrm{dom}(\sigma)$ is the disjoint union of the cycles $\mathrm{cyc}(\sigma, i(1))$ to $\mathrm{cyc}(\sigma, i(r))$, then σ can be written as the composition of the cycles $\zeta_{i(i)}$ to $\zeta_{i(r)}$ (in any order, as all the cycles are mutually commutative)

$$\mathrm{dom}(\sigma) \;=\; \bigcup_{j=1}^{r} \mathrm{cyc}(\sigma, i(j)) \quad\Longrightarrow\quad \sigma \;=\; \prod_{j=1}^{r} \zeta_{i(j)}$$

(ii) Let $\zeta_1, \dots, \zeta_k \in S_n$ and $\xi_1, \dots, \xi_t \in S_n$ be two sets of cycles, with pairwise disjoint domains, i.e.

$$\begin{aligned} i \neq j \in 1 \dots k \quad &\Longrightarrow \quad \mathrm{dom}(\zeta_i) \cap \mathrm{dom}(\zeta_j) = \emptyset \\ r \neq s \in 1 \dots t \quad &\Longrightarrow \quad \mathrm{dom}(\xi_r) \cap \mathrm{dom}(\xi_s) = \emptyset \end{aligned}$$

If now the compositions $\zeta_1 \dots \zeta_k = \xi_1 \dots \xi_t$ are equal, then we already get $k = t$ and there is some permutation $\alpha \in S_r$ such that for any $i \in 1 \dots k$ we get $\zeta_i = \xi_{\alpha(i)}$

$$\prod_{i=1}^{k} \zeta_i \;=\; \prod_{r=1}^{t} \xi_r \quad\Longrightarrow\quad \forall\, i \in 1 \dots k \;:\; \zeta_i = \xi_{\alpha(i)}$$

(iii) For any permutation $\sigma \in S_n$ with $\sigma \neq \mathbb{1}$ there is a uniquely determined **cyclic decomposition** $\{ \zeta_1, \dots, \zeta_r \}$ of σ. That is the $\zeta_1, \dots, \zeta_r \in S_n$ are cycles with pairwise disjoint domains (for any i, $j \in 1 \dots r$ that is $i \neq j \implies \mathrm{dom}(\zeta_i) \cap \mathrm{dom}(\zeta_j) = \emptyset$), such that σ can be written as a composition of these cycles. And this decomposition is unique, up to ordering the ζ_i

$$\sigma \;=\; \prod_{i=1}^{r} \zeta_i$$

(iv) Any permutation $\sigma \in S_n$ is a product of transpositions of two adjacent numbers. That is there are finitely many $i_0, \dots i_s \in \mathbb{N}$ such that for any $j \in 1 \dots r$ we get $|i_j - i_{j-1}| = 1$ and also

$$\sigma \;=\; \prod_{j=1}^{s} (i_{j-1} \;\; i_j)$$

(v) Two permutations ϱ and $\sigma \in S_n$ share the same cyclic structure if and only if they are conjugates of each other. Formally that is the equivalence of the following two statements

(a) If we decompose $\varrho = \zeta_1 \dots \zeta_k$ and $\sigma = \xi_1 \dots \xi_t$ into cycles, ζ_i and ξ_r respectively, with pairwise disjoint domains (as in (ii)), then we get $k = t$ and these cycles are of the same lengths. That is there is a permutation $\alpha \in S_k$ such that

$$\forall\, i \in 1 \dots k \;\; : \;\; \mathrm{ord}(\zeta_i) \;=\; \mathrm{ord}(\xi_{\alpha(i)})$$

(b) There is some permutation $\pi \in S_n$ such that $\sigma = \pi \varrho \pi^{-1}$.

(1.19) Example: Cyclic Decomposition:
Let us present a short example of a cyclic decomposition in $1 \dots 9$. To define or permutation $\sigma \in S_9$ we present a short table to fix σ

i	1	2	3	4	5	6	7	8	9
$\sigma(i)$	3	4	1	8	7	6	9	2	5

First of all it is clear that 6 is fixed under σ, hence it will not appear in our cyclic decomposition (it would yield a cycle of length 1, namely (6)). Now begin by 1 and extract its cycle. We see that $1 \mapsto 3 \mapsto 1$ so our first cycle is (1 3). The next number not dealt with is 2, which is cycled like $2 \mapsto 4 \mapsto 8 \mapsto 2$. So the second cycle is (2 4 8). As 3 and 4 occurred in the first and second cycles respectively, we continue with 5 which is moved like $5 \mapsto 7 \mapsto 9 \mapsto 5$. Thus the third cycle is (5 7 9). As 6 is fixed and $7 \dots 9$ have already been taken care of we have exhausted the whole domain of σ. Altogether we have seen that

$$\sigma \;=\; (1\,3)(2\,4\,8)(5\,7\,9)$$

Note that these cycles are uniquely determined even if there are several ways of putting them, e.g. $(2\ 4\ 8) = (4\ 8\ 2) = (8\ 2\ 4)$. Also it is possible to commute these cycles arbitrarily, without changing σ as they are mutually commutative. Finally we know, that any other permutation $\varrho \in S_9$ is conjugated to σ, if and only if it consists of 3 cycles of lengths 2,3,3 respectively.

(1.20) Definition:
Fix any $n \in \mathbb{N}$ with $n \geq 1$. If now σ is any permutation then we define the **signum** of this permutation to be the following number

$$\mathrm{sgn}(\sigma) \;:=\; \prod_{1 \leq i < j \leq n} \frac{\sigma(j) - \sigma(i)}{j - i}$$

It will turn out that the signum is contained in $\mathrm{sgn}(\sigma) \in \mathbb{Z}^* = \{-1, +1\}$. A permutation σ with $\mathrm{sgn}(\sigma) = 1$ is said to be **even**, whereas a permutation with $\mathrm{sgn}(\sigma) = -1$ is said to be **odd**. The set of all even permutations will be denoted, by

$$A_n \;:=\; \{\, \sigma \in S_n \mid \mathrm{sgn}(\sigma) = 1 \,\}$$

(1.21) Remark:
The product, that has been used to define the signum of σ might be a little obfuscated at a first glance. But in fact the indexes simply run over the set $\Delta := \{\, (i,j) \in (1 \ldots n)^2 \mid i < j \,\}$. And as the multiplication in $\mathbb{Q}$ is commutative the ordering of this set Δ has no effect on the result of the product. In other words

$$\mathrm{sgn}(\sigma) \;=\; \prod_{i=1}^{n-1} \prod_{j=i+1}^{n} \frac{\sigma(j) - \sigma(i)}{j - i}$$

As an example let us consider the case $\tau = (1\ 3) \in S_4$. Then the signum of the transposition τ can be computed, to be

$$\sigma(\tau) \;=\; \frac{2-3}{2-1} \cdot \frac{1-3}{3-1} \cdot \frac{4-3}{4-1} \cdot \frac{1-2}{3-2} \cdot \frac{4-2}{4-2} \cdot \frac{4-1}{4-3} \;=\; -1$$

(1.22) Proposition: (viz. 721)

(i) If $\sigma \in S_n$ is any permutation, then the signum of σ can be evaluated by counting the number of *inversions* of σ. That is the signum is given to be $\mathrm{sgn}(\sigma) = (-1)^{I(\sigma)}$ where

$$I(\sigma) \;:=\; \#\{\, (i,j) \in (1 \ldots n)^2 \mid i < j \text{ and } \sigma(i) > \sigma(j) \,\}$$

(ii) Let $\sigma \in S_n$ be a permutation and $\sigma = \zeta_1 \ldots \zeta_r$ be its decomposition into cycles with pairwise disjoint domains. Let $\ell(i) := \mathrm{ord}(\zeta_i)$ be the length of the i-th cycle. Then the order of σ is the least common multiple of the $\ell(i)$ and we can easily compute the signum of σ as well

$$\begin{aligned} \mathrm{ord}(\sigma) &= \mathrm{lcm}(\ell(1), \ldots, \ell(r)) \\ \mathrm{sgn}(\sigma) &= \prod_{i=1}^{r} (-1)^{\ell(i)-1} \end{aligned}$$

(iii) If $\sigma \in S_n$ is decomposed into the transpositions τ_i that is $\sigma = \tau_1 \tau_2 \ldots \tau_r$ where (for any $i \in 1 \ldots r$) τ_i is a cycle of length 2, then the signum of σ is just

$$\mathrm{sgn}(\sigma) \;=\; (-1)^r$$

(iv) For any $n \in \mathbb{N}$ with $n \geq 1$ the signum is a group homomorphism of the form $\mathrm{sgn} : S_n \to \mathbb{Z}^*$. That is for any $\varrho, \sigma \in S_n$ we get

$$\mathrm{sgn}(\varrho\sigma) \;=\; \mathrm{sgn}(\varrho) \cdot \mathrm{sgn}(\sigma)$$

(v) $(\diamondsuit)$ For any $n \in \mathbb{N}$ with $n \geq 2$ we find that $A_n \trianglelefteq_n S_n$ is a normal subgroup of S_n that has precisely half as many elements, as S_n does, that is

$$\#A_n \;=\; \frac{n!}{2}$$

1.3 Defining Rings

In the previous section we have introduced an atomic component - groups (and their generalizations monoids and groupoids). We have also introduced some notation, that we employ whenever we are dealing with these objects. We will glue two groupoids over the same set R together - that is we consider a set equipped with two binary relations $+$ and $\cdot$ that are compatible in some way (by distributivity). Note that we again write $a+b$ instead of $+(a,b)$ and likewise $a \cdot b$ (or shorthand ab only) for $\cdot(a,b)$. These objects will be called rings and we will dedicate the entire first part of this book to rings and the structure they may have.

(1.23) Definition:
Let $R \neq \emptyset$ be any non-empty set and consider two binary operations $+$ called **addition** and $\cdot$ called **multiplication** on R. And the ordered tripel $(R,+,\cdot)$ is said to be **ringoid** iff it satisfies both of the following properties (A) and (D), where

$$\begin{aligned} + \;&:\; R \times R \to R \;&:\; (a,b) \mapsto a+b \\ \cdot \;&:\; R \times R \to R \;&:\; (a,b) \mapsto a \cdot b \end{aligned}$$

(A) $(R,+)$ is a commutative group, that is the addition is *associative* and *commutative*, admits a neutral element (called *zero-element* and denoted by 0) and every element of R has an additive inverse. Formally that is

$$\begin{aligned} \forall\, a,b,c \in R \;&:\; a+(b+c) \;=\; (a+b)+c \\ \forall\, a,b \in R \;&:\; a+b \;=\; b+a \\ \exists\, 0 \in R\; \forall\, a \in R \;&:\; a+0 \;=\; a \\ \forall\, a \in R\; \exists\, n \in R \;&:\; a+n \;=\; 0 \end{aligned}$$

Note that the **zero-element** 0 thereby is already uniquely determined and hence the fourth property makes sense. Further, if we are given $a \in R$, then the element $n \in R$ with $a+n=0$ is uniquely determined, and we call it the **negative** of a, denoted by $-a := n$.

(D) The addition and multiplication on R respect the following *distributivity laws*, i.e. $\forall\, a,b,c \in R$ we have the properies

$$\begin{aligned} a \cdot (b+c) \;&=\; (a \cdot b)+(a \cdot c) \\ (a+b) \cdot c \;&=\; (a \cdot c)+(b \cdot c) \end{aligned}$$

As is the structure of a ringoid is very general and hence hard to pin down. We will consider rings and commutative rings only, where the multiplication also is a (commutative) monoid. The prominent examples of matrix algebras and the integers are of this kind and we will see, that in this case we can tell a lot about the structure of such rings.

(1.24) Definition:
In the following let $(R,+,\cdot)$ be a ringoid, then we consider a couple ofvadditional properties (S), (R) and (C), that R may or may not have and introduce names to these

(C) The multiplication $\cdot$ on R is *commutative*, that is we have the property

$$\forall\, a,b,c \in R \;:\; a\cdot b \;=\; b\cdot a$$

(S) The multiplication $\cdot$ on R is *associative*, that is we have the property

$$\forall\, a,b,c \in R \;:\; a\cdot(b\cdot c) \;=\; (a\cdot b)\cdot c$$

(R) The multiplication $\cdot$ on R admits a *neutral element* 1, that is we have property

$$\exists 1 \in R\ \forall\, a \in R \;:\; 1\cdot a \;=\; a \;=\; a\cdot 1$$

Note that the neutral element 1 of the multiplication of R already is uniquely determined and will be called the **unit-element** of R.

(F) Let us assume that R satisfies properties (S) and (R), then we define property (F): Every non-zero element R has an *inverse element*, that is

$$\forall\, 0 \neq a \in R\ \exists\, i \in R \;:\; a\cdot i \;=\; 1 \;= i\cdot a$$

Note that 1 is given by (R) and due to (S) the element $i \in R$ is uniquely determined by a. We call i the **inverse** of a, denoted by $a^{-1} := i$.

Using these properties we define the following notions: Let $(R,+,\cdot)$ be a ringoid, then $(R,+,\cdot)$ is even said to be **commutative** resp. called a **semi-ring**, **ring**, **skew-field** of even **field**, iff

commutative	$:\Longleftrightarrow$	(C)
semi-ring	$:\Longleftrightarrow$	(S)
ring	$:\Longleftrightarrow$	(S) and (R)
commutative ring	$:\Longleftrightarrow$	(S), (R) and (C)
skew-field	$:\Longleftrightarrow$	(S), (R), (F) and $0 \neq 1$
field	$:\Longleftrightarrow$	(S), (R), (C), (F) and $0 \neq 1$

Nota in the mathematical literature the word *ring* may have many different meanings, depending of what topic a given text pursues. While some authors do not assume rings to have a unit (or even not be associative) others assume them to always be commutative. Hence it also is customary to speak of a *non-unital ring* in case of a semi-ring and of a *unital ring* in case of a ring.

(1.25) Remark:
Let $(R,+,\cdot)$ be a ringoid, then we simplify our notation somewhat by introducing the following conventions

- The zero-element of any ringoid R is denoted by 0. If we deal with several ringoids simultaneously then we will write 0_R to emphasize, which ringoid the zero-element belongs to.
- Analogously the unit element of any ring R is denoted by 1 and by 1_R if we wish to stress the ring R. For some specific rings we will use a different symbol than 1, e.g. $\mathbf{1}$ or $\mathbb{1}$.
- In order to save some parentheses we agree that the multiplication $\cdot$ is of higher priority than the addition $+$, e.g. from now on $ab+c$ shall abbreviate $(a\cdot b)+c$.
- The addition of the additive inverse is sometimes used just like a binary operation itself, i.e. $a-b$ stands shortly for $a+(-b)$.
- We have introduced the multiplicative inverse a^{-1} of a and we use the convention that the inversion is of higher priority, than the multiplication itself, i.e. ab^{-1} stands shortly for $a\cdot(b^{-1})$.
- If $a_1,\ldots,a_n\in R$ are finitely many elements of R, then we denote the **sum** and **product** of these to be the following element of R again

$$\begin{aligned}\sum_{i=1}^{n} a_i &:= \Big((a_1+a_2)+\ldots\Big)+a_n\\ \prod_{i=1}^{n} a_i &:= \Big((a_1\cdot a_2)\cdot\ldots\Big)\cdot a_n\end{aligned}$$

- For some integer $k\in\mathbb{Z}$ we now introduce the following abbreviations

$$ka := \begin{cases} \sum_{i=1}^{k} a \text{ for } k>0\\ 0 \text{ for } k=0\\ \sum_{i=1}^{-k}(-a) \text{ for } k<0\end{cases}$$

$$a^k := \begin{cases} \prod_{i=1}^{k} a \text{ for } k>0\\ 1 \text{ for } k=0\\ \prod_{i=1}^{-k}(a^{-1}) \text{ for } k<0\end{cases}$$

 For the definition of a^k we, of course, required R to be a ring in the case $k=0$ and even that a is *invertible* (refer to the next section for this notion) in the case $k<0$.

(1.26) Remark:

- Consider any ringoid $(R, +, \cdot)$, then the addition $+$ on R is associative by definition. Hence the result of the sum $a_1 + \cdots + a_n \in R$ does not depend on the way we applied parentheses to it (cf. (1.2)). Therefore we may equally well omit the bracketing in the summation, writing

$$a_1 + \cdots + a_n \;:=\; \sum_{i=1}^{n} a_i$$

 The same is true for the multiplication $\cdot$ in a semi-ring $(R, +, \cdot)$. So by the same reasoning we omit the brackets in products, writing

$$a_1 \ldots a_n \;:=\; \prod_{i=1}^{n} a_i$$

- By definition the addition $+$ of a ringoid $(R, +, \cdot)$ also is commutative. Thus the sum $a_1 + \cdots + a_n \in R$ does not even depend on the ordering of the a_i (refer to (1.2) again). Now take any finite set Ω and regard a mapping $a : \Omega \to R$. Then we may even define the sum over the unordered set Ω. To do this fix any bijection of the form $\sigma : 1 \ldots n \longleftrightarrow \Omega$ (in particular $n := \#\Omega$). Then we may define

$$\sum_{i \in \Omega} a(i) \;:=\; \begin{cases} 0 \text{ if } \Omega = \emptyset \\ \sum_{i=1}^{n} a(\sigma(i)) \text{ if } \Omega \neq \emptyset \end{cases}$$

 The same is true for the multiplication $\cdot$ in a commutative semi-ring $(R, +, \cdot)$. So given $a : \Omega \to R$ and σ as above we define (note that the case $\Omega = \emptyset$ even requires R to be a commutative ring)

$$\prod_{i \in \Omega} a(i) \;:=\; \begin{cases} 1 \text{ if } \Omega = \emptyset \\ \prod_{i=1}^{n} a(\sigma(i)) \text{ if } \Omega \neq \emptyset \end{cases}$$

- If I is infinite but the set $\Omega := \{\, i \in I \mid a(i) \neq 0 \,\}$ is finite still we write an infinte sum over all $i \in I$, that actually is defined by a finite sum

$$\sum_{i \in I} a(i) \;:=\; \sum_{i \in \Omega} a(i)$$

 If R is a commutative ring and analogously $\Omega := \{\, i \in I \mid a(i) \neq 1 \,\}$ is finite then the same is true for the infinite product

$$\prod_{i \in I} a(i) \;:=\; \prod_{i \in \Omega} a(i)$$

1.4 Examples

(1.27) Example:

- The most well-known example of a commutative ring are the integers $(\mathbb{Z}, +, \cdot)$. And they are a most beautiful ring indeed - e.g. $\mathbb{Z}$ does not contain zero-divisors (that is $ab = 0$ implies $a = 0$ or $b = 0$). And we only wish to remark here that $\mathbb{Z}$ is an UFD (that is any $a \in \mathbb{Z}$ admits a unique primary decomposition) - this will be the formulated and proved as the fundamental theorem of arithmetic.
- Now regard the set $2\mathbb{Z} := \{ 2a \mid a \in \mathbb{Z} \}$ of even integers. It is easy to see, that the sum and product of even numbers again is even. Hence $(2\mathbb{Z}, +, \cdot)$ is a (commutative) semi-ring under the operations inherited from $\mathbb{Z}$. Yet it does not contain a unit element 1 and hence does not qualify to be a ring.
- Next we will regard a somewhat strange ring, the so called *zero-ring* Z. As a set it is defined to be $Z := \{0\}$ (with $0 \in \mathbb{Z}$ if you wish). As it solely contains one point 0 it is clear how the binary operations have to be defined $0 + 0 := 0$ and $0 \cdot 0 := 0$. It is esy to check that $(Z, +, \cdot)$ thereby becomes a commutative ring in which $1 = 0$. We will soon see that Z even is the only ring in which $1 = 0$ holds true. In this sense this ring is a bit pathological.
- Now consider an arbitrary (commutative) ring $(R, +, \cdot)$ and a non-empty set $I \neq \emptyset$. Then the set R^I of functions from I to R can be turned into another (commutative) ring $(R^I, +, \cdot)$ under the *point-wise* operations of functions

$$R^I := \{ f \mid f : I \to R \}$$

$$f + g : I \to R : i \mapsto f(i) + g(i)$$

$$f \cdot g : I \to R : i \mapsto f(i) \cdot g(i)$$

- Let X be any set and denote its *power set* by $\mathcal{P}(X) := \{ A \mid A \subseteq X \}$. And for any subsets A, $B \subseteq X$ we define the *symmetric difference* $A \,\Delta\, B := (A \cup B) \setminus (A \cap B) = (A \setminus B) \cup (B \setminus A) \subseteq X$. Thereby $(\mathcal{P}(X), \Delta, \cap)$ becomes a commutative ring with zero-element $\emptyset$ and unit element X. And if $A \subseteq X$ is any subset, then the additive inverse of A is just $-A = A$ again.
- The next ring we study are the rational numbers $(\mathbb{Q}, +, \cdot)$. It is well-known that $\mathbb{Q}$ even is a field - if $a/b \neq 0$ then $a \neq 0$ and hence $(a/b)^{-1} = (b/a)$ is invertible. We will even present a construction of gaining $\mathbb{Q}$ from $\mathbb{Z}$ in example (1.31), in this section.
- Most of the previous examples have been quite large (considering the number of elements involved). We would now like to present an example of a finite field consisting of precisely four elements $F = \{ 0, 1, a, b \}$. As F is finite, we may give the addition and multiplication in tables

$+$	0	1	a	b
0	0	1	a	b
1	1	0	b	a
a	a	b	0	1
b	b	a	1	0

$\cdot$	0	1	a	b
0	0	0	0	0
1	0	1	a	b
a	0	a	b	1
b	0	b	1	a

(1.28) Example:
Having introduced $\mathbb{Z}$, $\mathbb{Q}$ and the reals $\mathbb{R}$ we would like to turn our attention to another important case - the *residue rings* of $\mathbb{Z}$. First note, that the integers $\mathbb{Z}$ allow a division with remainder (cf. to section 2.7). That is if we fix $2 \leq n \in \mathbb{N}$ then for any $a \in \mathbb{Z}$ then there are uniquely determined numbers $q \in \mathbb{Z}$ and $r \in 0 \ldots (n-1)$ such that

$$a \;=\; qn + r$$

Thereby r is called the *remainder* of a in the integer division of a times n. Formally one denotes (which is common in programming languages) the following operations

$$\begin{aligned} a \text{ div } n &:= q \\ a \text{ mod } n &:= r \end{aligned}$$

And by virtue of this operation "mod" we may now define the residue ring $(\mathbb{Z}_n, +, \cdot)$ of $\mathbb{Z}$ modulo n. First let $\mathbb{Z}_n := \{\, 0, 1, \ldots, n-1 \,\}$ as a set. And if a, $b \in \mathbb{Z}_n$, then we define the operations

$$\begin{aligned} a + b &:= (a + b) \text{ mod } n \\ a \cdot b &:= (a \cdot b) \text{ mod } n \end{aligned}$$

Thereby $(\mathbb{Z}_n, +, \cdot)$ will in fact be a commutative ring. And $\mathbb{Z}_n$ will be a field if and only if n is a prime number. We will soon give a more natural construction of $\mathbb{Z}_n$ as the quotient $\mathbb{Z}/n\mathbb{Z}$, as this will be far better suited to derive the properties of this ring.

(1.29) Example: (viz. 724)
Any semi-ring $(S, +, \cdot)$ can be embedded into a ring. In this sense the theory sub-semi-rings of rings encompassed the theory of semi-rings. The construction can be done in the following way: Take R to be the set $R := \mathbb{Z} \times S$ and equip R with the following two operations for any a, $b \in \mathbb{Z}$ and x, $y \in S$

$$\begin{aligned} (a, x) + (b, y) &:= (a + b, x + y) \\ (a, x) \cdot (b, y) &:= (ab, ay + bx + xy) \end{aligned}$$

Then $(R, +, \cdot)$ becomes a ring with zero-element $0_R = (0, 0_S)$ and unit $1_R = (1, 0_S)$. Note that R is commutative, if and only if S is commutative. And we can interpret S as a sub-ring of R under the canonical embedding [that is injective and satisfies $\iota(x + y) = x + y$ and $\iota(xy) = xy$]

$$\iota : S \hookrightarrow R : x \mapsto (0, x)$$

(1.30) Example: $(\diamondsuit)$

Let $(R,+,\cdot)$ be an arbitrary ring, we will later employ the **opposite ring** $(R,+,\cdot)^{\mathrm{op}}$ of R. This is defined to be R as a set, under the same addition $+$ but with a multiplication that reverses the order of elements. Formally

$$(R,+,\cdot)^{\mathrm{op}} := (R,+,\circ) \quad \text{where} \quad a \circ b := b \cdot a$$

Note that thereby $(R,+,\cdot)^{\mathrm{op}}$ is a ring again with the same properties as $(R,+,\cdot)$ before. And if $(R,+,\cdot)$ has been commutative, then the opposite ring of R is just R itself, i.e. $(R,+,\cdot)^{\mathrm{op}} = (R,+,\cdot)$.

(1.31) Example:

Let $(R,+,\cdot)$ be an *integral domain*, that is $R \neq 0$ is a non-zero commutative ring such that for any two elements a, $b \in R$ we have: Whenever $ab = 0$ then we necessarily have $a = 0$ or $b = 0$. In this case we take to the set $X := R \times (R \setminus \{0\})$ and obtain an equivalence relation $\sim$ on X by letting

$$(a,u) \sim (b,v) \quad :\Longleftrightarrow \quad av = bu$$

for any (a,u) and $(b,v) \in X$. If now $(a,u) \in X$ then we denote its equivalence class by a/u, and let us denote the quotient set of X modulo $\sim$ by Q. Formally that is

$$\begin{aligned} \frac{a}{u} &:= \{\, (b,v) \in X \mid av = bu \,\} \\ Q &:= \left\{ \frac{a}{u} \;\middle|\; a,b \in R,\ b \neq 0 \right\} \end{aligned}$$

Thereby Q becomes a commutative ring (with zero-element $0/1$ and unit element $1/1$) under the following (well-defined) addition and multiplication

$$\begin{aligned} \frac{a}{u} + \frac{a}{u} &:= \frac{av + bu}{uv} \\ \frac{a}{u} \cdot \frac{a}{u} &:= \frac{ab}{uv} \end{aligned}$$

In fact $(Q,+,\cdot)$ even is a field, called the *quotient field* of R. This is due to the fact that the inverse of $a/u \neq 0/1$ is given to be $(a/u)^{-1} = u/a$. This construction will be vastly generalized in section 2.10. Note that this is precisely the way to obtain the rationals $\mathbb{Q} := Q$ by starting with $R = \mathbb{Z}$.

(1.32) Example:

Consider an arbitrary ring $(R,+,\cdot)$ and $1 \leq n \in \mathbb{N}$, then an $(n \times n)$-*matrix* over R is a mapping of the form $A : (1 \ldots n) \times (1 \ldots n) \to R$. And we denote the set of all such maps by $\mathrm{mat}_n(R)$ that is $\mathrm{mat}_n(R) := \{\, A \mid A : (1 \ldots n) \times (1 \ldots n) \to R \,\}$. Usually a matrix is written as an array of the following form (where $a_{i,j} := A(i,j)$)

$$A \;=\; \left(a_{i,j}\right) \;=\; \begin{pmatrix} a_{1,1} & \cdots & a_{1,n} \\ \vdots & \ddots & \vdots \\ a_{n,1} & \cdots & a_{n,n} \end{pmatrix}$$

And using this notation we may turn $\mathrm{mat}_n(R)$ into a (non-commutative even if R is commutative) ring by defining the addition and multiplication

$$\Big(a_{i,j}\Big) + \Big(b_{i,j}\Big) \;:=\; \Big(a_{i,j} + b_{i,j}\Big)$$

$$\Big(a_{i,j}\Big) \cdot \Big(b_{i,j}\Big) \;:=\; \left(\sum_{s=1}^{n} a_{i,s}\, b_{s,j}\right)$$

It is immediately clear from the construction, that the zero-element, resp. the unit-element are given by the *zero-matrix* and *unit-matrix* respectively

$$0 \;=\; \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & 0 \end{pmatrix}$$

$$1 \;=\; \begin{pmatrix} 1 & & 0 \\ & \ddots & \\ 0 & & 1 \end{pmatrix}$$

(1.33) Example:
The following construction is of astounding importance. We will generalize it to several variablen, in (7.21). In fact we will dedicate the entire chapter 7 to it. But we will already use the one-variable case before, so make sure you understand the following construction: Let $(R, +, \cdot)$ be any commutative ring, we first define the (commutative) ring of *formal power series* over R, to be the set of functions from $\mathbb{N}$ to R. That is, as a set set, we define $R[\![t]\!]$ to be

$$R[\![t]\!] \;:=\; \{\, f \mid f : \mathbb{N} \to R \,\}$$

For any $f \in R[\![t]\!]$ we will write $f[k]$ instead of $f(k)$, that is $f : k \mapsto f[k]$. Further we denote f in the following form (note that this is purely notational and *not* a true sum)

$$\sum_{k=0}^{\infty} f[k]\, t^k \;:=\; f$$

And thereby we may define the sum and product of two formal power series $f, g \in R[\![t]\!]$, by point-wise summation $f + g : k \mapsto f[k] + g[k]$ and the involution $f \cdot g : k \mapsto f[0]g[k] + f[1]g[k-1] + \cdots + f[k]g[0]$. In terms of the above notation that is

$$f + g \;:=\; \sum_{k=0}^{\infty} \Big(f[k] + g[k]\Big) t^k$$

$$f \cdot g \;:=\; \sum_{k=0}^{\infty} \left(\sum_{i+j=k} f[i]g[j]\right) t^k$$

An elementary computation (cf. section 7.2) shows that $(R[\![t]\!], +, \cdot)$ truly becomes a commutative ring. The zero-element of this ring is given by $0 : k \mapsto 0$ and the unit element is $\mathbf{1} = t^0 : k \mapsto \delta(k,0)$. The element $t : k \mapsto \delta(k,1)$ plays another central role. An easy computation shows that for any $n \in \mathbb{N}$ we get $t^n : k \mapsto \delta(k,n)$. If now $0 \neq f \in R[\![t]\!]$ is a non-zero formal power series we define the *degree* of f

$$\deg(f) \;:=\; \sup\{\, k \in \mathbb{N} \mid f[k] \neq 0 \,\} \;\in\; \mathbb{N} \cup \{\infty\}$$

That is $\deg(f) < \infty$ just states that the set $\{\, k \in \mathbb{N} \mid f[k] \neq 0 \,\}$ is a finite subset of $\mathbb{N}$. And thereby we define the *polynomial ring* over R to be set of power series of finite degree

$$R[t] \;:=\; \{\, f \in R[\![t]\!] \mid \deg(f) < \infty \,\}$$

By definition $R[t] \subseteq R[\![t]\!]$ is a subset, but one easily verifies, that $R[t]$ even is another commutative ring under the addition and multiplication inherited from $R[\![t]\!]$. Further note that every polynomial $f \in R[t]$ now truly is a finite sum of the form

$$f \;=\; \sum_{k=0}^{\infty} f[k]\, t^k$$

If $f \in R[t]$ the highest non-zero coefficient of f will be called the **leading coefficient** of f, denoted by $\mathrm{lc}(f)$. And f is said to be a **monic** polynomial, iff $f \neq 0$ and its leading coefficient is $1 \in R$

$$\mathrm{lc}(f) \;:=\; \begin{cases} f[\deg(f)] \text{ if } f \neq 0 \\ 0 \text{ if } f = 0 \end{cases} \;\in\; R$$

(1.34) Remark:
The field of real numbers is a very peculiar one. You most probably know it from high school already, although it actually is not so simple, at all. If it wasn't used so frequently, we would well postpone it until much later. Stick to the intuition, that the real numbers x is expressions of the form $x = a + 0.d_1d_2d_3\ldots$, where $a \in \mathbb{Z}$ is an integer and the d_i are digits $d_i \in 0\ldots9$. Then the value of x is

$$x \;=\; a + \sum_{i=1}^{\infty} d_i\, 10^{-i}$$

Actually this rather is a way of addressing x, as a point on a line, than a value. But we will set out onto a lengthy journey to give a meaning to this. The best way to deal with the field $\mathbb{R}$ of reals is understanding the following list of properties, that uniquely determine $\mathbb{R}$ (up to isomorphy). First of all $(\mathbb{R}, +, \cdot)$ is a field of course. But there also is a *total order* $\leq$ on $\mathbb{R}$ - in the sense of (0.17) - that also is *positive* - in the sense of (1.87). That is $\leq$ is a total order, such that $0 \leq 1$ for any $x, y \in \mathbb{R}$ we have

(1) $x \leq y \iff 0 \leq y - x$

(2) $0 \leq x, y \implies 0 \leq x + y$

(3) $0 \leq x, y \implies 0 \leq xy$

These properties have several consequences, in themselves, as we will see in section (1.8). But $\mathbb{R}$ also has the following *supremum property*: Recall, that for a subset $A \subseteq \mathbb{R}$ and $b \in \mathbb{R}$ we defined $A \leq b$ by $\forall\, a \in A : a \leq b$. Such a b is said to be an *upper bound* of A. Now

(4) If A is a non-empty set of real numbers, that A has an upper bound, there A already has a minimal upper bound s. Formally put this property reads as

$$\begin{aligned} \forall\, A \subseteq \mathbb{R} \;\; &: \;\; A \neq \emptyset \text{ and } \exists\, b \in \mathbb{R} : A \leq b \\ \exists\, s \in \mathbb{R} \;\; &: \;\; A \leq s \text{ and } \forall\, b \in \mathbb{R} : A \leq b \implies s \leq b \end{aligned}$$

This minimal upper bound s then is uniquely determined and will be denoted, by $s = \sup(A)$. Prob suppose that both, r and s have this property, then in particular $A \leq r$ and $A \leq s$. But as both r and s are minimal with this property, we get $s \leq r$ and $r \leq s$ such that $r = s$.

($\diamondsuit$) We recommend, that the reader takes these properties for granted. For the more experienced reader we want to continue by giving an algebraic construction of $\mathbb{R}$, of which it can be shown, that is satisfies these properties: Let us denote the sets of Cauchy-sequences and zero-sequences over the rational numbers $\mathbb{Q}$ respectively

$$\mathcal{C} \;:=\; \left\{ (q_n) \subseteq \mathbb{Q} \;\middle|\; \begin{array}{l} \forall\, k \in \mathbb{N}\; \exists\, n(k) \in \mathbb{N} \\ \forall\, m,n \geq n(k) \;:\; |q_n - q_m| < 1/k \end{array} \right\}$$

$$\mathfrak{z} \;:=\; \left\{ (q_n) \subseteq \mathbb{Q} \;\middle|\; \begin{array}{l} \forall\, k \in \mathbb{N}\; \exists\, n(k) \in \mathbb{N} \\ \forall\, n \geq n(k) \;:\; |q_n| < 1/k \end{array} \right\}$$

Then $\mathcal{C}$ becomes a commutative ring under the point-wise operations $(p_n) + (q_n) := (p_n + q_n)$ and $(p_n)(q_n) := (p_n q_n)$ of maps. And $\mathfrak{z} \trianglelefteq_{\mathrm{i}} \mathcal{C}$ is a maximal ideal of $\mathcal{C}$ (cf. to section 2.1). Now the reals can be introduced as the quotient (cf. to section 1.6) of $\mathcal{C}$ modulo $\mathfrak{z}$

$$\mathbb{R} \;:=\; \mathcal{C} \Big/ \mathfrak{z}$$

As $\mathfrak{z}$ has been maximal $\mathbb{R}$ becomes a field (see 2.5). Thereby $\mathbb{Q}$ can be embedded into $\mathbb{R}$, by virtue of $\mathbb{Q} \hookrightarrow \mathbb{R} : q \mapsto (q)$. And we obtain a positive order on $\mathbb{R}$ by letting $(p_n) + \mathfrak{z} \leq (q_n) + \mathfrak{z}$ iff $\exists\, m \in \mathbb{N}\; \forall\, n \geq m : p_n \leq q_n$. Note that this *completion* of $\mathbb{Q}$ (that is Cauchy-sequences modulo zero-sequences) can be generalized to arbitrary metric spaces (see section 3.14). Its effect is that the resulting space becomes *complete* (that is Cauchy sequences are already convergent). In our case this also guarantees the supremum-property. And with this construction we are finally able to give meaning to the representation of x as a decimal number. The x at the beginning of this example is $x = (q_n) + \mathfrak{z}$, where

$$q_n \;=\; a + \sum_{i=1}^{n} d_i\, 10^{-i} \;\in\; \mathbb{Q}$$

(1.35) Example:
The complex numbers $(\mathbb{C}, +, \cdot)$ also form a field (that even has a lot of properties that make it better-behaved than the reals). We want to present three (isomorphic) ways of introducing $\mathbb{C}$ now:

(1) First of all define $\mathbb{C} := \mathbb{R}^2$ to be the real plane. For any two complex numbers $z = (a,b)$ and $w = (c,d)$ we define the operations

$$\begin{pmatrix} a \\ b \end{pmatrix} + \begin{pmatrix} c \\ d \end{pmatrix} \;:=\; \begin{pmatrix} a+c \\ b+d \end{pmatrix}$$

$$\begin{pmatrix} a \\ b \end{pmatrix} \cdot \begin{pmatrix} c \\ d \end{pmatrix} \;:=\; \begin{pmatrix} ad-bc \\ ac+bd \end{pmatrix}$$

The advantage of this construction is, that it is purely elementary. The disadvantage is that one has to check that $(\mathbb{C},+,\cdot)$ truly becomes a field under these operations (which we leave as an exercise). We only present the inverse of $(0,0) \neq z = (a,b) \in \mathbb{C}$. Define the *complex conjugate* of z to be $\overline{z} := (a,-b)$ and let $\nu(z) := z\overline{z} = a^2+b^2 \in \mathbb{R}$, then $z^{-1} = (a\nu(z)^{-1}, -b\nu(z)^{-1})$. Let us now denote $1 = (1,0)$ and $i = (0,1) \in \mathbb{C}$, then it is clear, that 1 is the unit element of $\mathbb{C}$ and that $i^2 = -1$. Further any $z = (a,b) \in \mathbb{C}$ can be written uniquely, as $z = a1 + bi$. It is customary to write $z = a + ib$ for this however.

(2) $(\diamondsuit)$ The next construction will imitate the one in (1) - yet it realizes (a,b) as a real (2×2)-matrix. This has the advantage, that addition and multiplication are well-known for matrices

$$\mathbb{C} \;:=\; \left\{ \begin{pmatrix} a & b \\ -b & a \end{pmatrix} \;\middle|\; a,b \in \mathbb{R} \right\}$$

It is straightforward to see that $\mathbb{C}$ thereby becomes a field under the addition and multiplication of matrices, that coincides with the one introduced in (1) (check this, it's neat). Note that thereby the determinant plays the role of $\nu(z) = \det(z)$ and the transposition of matrices is the complex conjugation $\overline{z} = z^*$.

(3) $(\diamondsuit)$ The third method implements the idea that i is introduced in such a way as to $i^2 = -1$. We simply force a solution of $t^2+1 = 0$ into $\mathbb{C}$

$$\mathbb{C} \;:=\; \mathbb{R}[t] \Big/ (t^2+1)\mathbb{R}[t]$$

Comparing this construction with the one in (1) we have to identify (a,b) with $a + bt + (t^2+1)\mathbb{R}[t]$. In particular $i = t + (t^2+1)\mathbb{R}[t]$. Then it again is easy to see, that addition and multiplication coincide under this identification. The advantage of this construction is that it focusses on the idea of finding a solution to $t^2+1 = 0$ (namely i), that $\mathbb{C}$ immediately is a field (as t^2+1 is prime, $\mathbb{R}[t]$ is a PID and hence $(t^2+1)\mathbb{R}[t]$ is maximal). The disadvantage is that it already requires the algebraic machinery, which remains to be introduced here. We will generalize this in (7.76).

(1.36) Example: $(\diamondsuit)$

Let us now present an example of an infinite commutative group, that is a subgroup of the multiplicative group $\mathbb{C}^*$ of the complex numbers. Fix any prime number $2 \leq p \in \mathbb{Z}$, then we let

$$\Gamma_p \;:=\; \left\{ \exp\left(\frac{2m\pi i}{p^n}\right) \;\middle|\; m,\, n \in \mathbb{N} \right\}$$

Thereby the operation of Γ_p is just the multiplication of complex numbers (as Γ_p is a subgroup of $\mathbb{C}^*$). For the inverse of an element in Γ_p choose some $k \in \mathbb{N}$ such that $kp^n > m$, then

$$\exp\left(\frac{2m\pi i}{p^n}\right)^{-1} \;=\; \exp\left(\frac{2(kp^n-m)\pi i}{p^n}\right)$$

(1.37) Example: $(\diamondsuit)$

Now fix any square-free $0 \neq d \in \mathbb{Z}$ (d being *sqare-free* means that there is no prime number $p \in \mathbb{Z}$ such that p^2 divides d). Then we define the following subset of the real resp. complex numbers

$$\mathbb{Z}[\sqrt{d}] \;:=\; \left\{ a + b\sqrt{d} \mid a, b \in \mathbb{Z} \right\}$$

Note that $\mathbb{Z}[\sqrt{d}]$ is contained in the reals if and only if $0 < d$, and in the case of $d < 0$ we have $\sqrt{d} = i\sqrt{-d} \in \mathbb{C}$. In any case $\mathbb{Z}[\sqrt{d}]$ becomes a commutative ring under the addition and multiplication inherited from $\mathbb{C}$

$$\begin{aligned} (a + b\sqrt{d}) + (e + f\sqrt{d}) &= (a + e) + (b + f)\sqrt{d} \\ (a + b\sqrt{d}) \cdot (e + f\sqrt{d}) &= (ae + dbf) + (af + be)\sqrt{d} \end{aligned}$$

It will be most interesting to see how the algebraic properties of these rings vary with d. E.g. for $d \in \{ -2, -1, 2, 3 \}$ the ring $\mathbb{Z}[\sqrt{d}]$ will be an Euclidean domain under $v(a + b\sqrt{d}) := |a^2 - db^2|$ as an Euclidean function. Yet $\mathbb{Z}[\sqrt{d}]$ will not even be an UFD for $d \leq -3$.

(1.38) Example:

We have just introduced the complex numbers as a two-dimensional space $\mathbb{R}$ over the reals. The next (and last sensibly possible, cf. to the Theorem of Frobenius) step in the hierarchy leads us to the *quaternions* $\mathbb{H}$. These are defined to be a four-dimensional, space $\mathbb{H} := \mathbb{R}^4$ over the reals. And analogous to the above we specifically denote four elements

$$\begin{aligned} 1 &:= (1, 0, 0, 0) \\ i &:= (0, 1, 0, 0) \\ j &:= (0, 0, 1, 0) \\ k &:= (0, 0, 0, 1) \end{aligned}$$

That is any element $z = (a, b, c, d) \in \mathbb{H}$ can be written uniquely, in the form $z = a + ib + jc + kd$. The addition of elements of $\mathbb{H}$ is point-wise and the multiplication is then given by linear expansion of the following multiplication table for these basis elements

	1	i	j	k
1	1	i	j	k
i	i	-1	k	-j
j	j	-k	-1	i
k	k	j	-i	-1

For $z = a + ib + jc + kd$ and $w = p + iq + jr + ks \in \mathbb{H}$ these operations explicitly read as

$$\begin{aligned} z + w &= (a + p) + i(b + q) + j(c + r) + k(d + s) \\ zw &= (ap - bq - cr - ds) + i(aq + bp + cs - dr) \\ &\quad + j(ar - bs + cp + dq) + k(as + br - cq + dp) \end{aligned}$$

As with the complex numbers we define a *conjugation* on $\mathbb{H}$ by letting $\overline{z} := a - ib - jc - kd$. We also define $\nu(z) = z\overline{z} = a^2 + b^2 + c^2 + d^2 \in \mathbb{R}$ and the *real* and $\mathrm{re}(z) := a \in \mathbb{R}$ and *imaginary part* $\mathrm{im}(z) := (b, c, d) \in \mathbb{R}^3$ of z. Then the inverse of any $z \neq 0$ can be computed as

$$z^{-1} \;=\; \nu(z)^{-1}\overline{z} \;=\; \Big(a\nu(z)^{-1}, -b\nu(z)^{-1}, -c\nu(z)^{-1}, -d\nu(z)^{-1}\Big)$$

Yet $\mathbb{H}$ clearly is not commutative, as $ij = k = -ji$. Thus the quaternions form a skew-field, but not a field. Using the complex numbers $\mathbb{C}$ we may also realize the quaternions as (2×2)-matrices over $\mathbb{C}$. Given $a + ib + jc + kd \in \mathbb{H}$ we pick up the complex numbers $z = a + ib$ and $w = c + id \in \mathbb{C}$ and identify $a + ib + jc + kd$ with a (2×2)-matrix of the following form

$$\mathbb{H} \;\cong_{\mathsf{r}}\; \left\{ \left(\begin{array}{cc} z & w \\ -\overline{w} & \overline{z} \end{array} \right) \;\middle|\; z, w \in \mathbb{C} \right\}$$

$(\diamondsuit)$ Let us analyse the multiplication a little further: For $a \in \mathbb{R}$ and $u = (b, c, d) \in \mathbb{R}^3$ let us denote $(a, u) := a + ib + jc + kd \in \mathbb{H}$. Likewise we get $w = (p, v)$ for $v = (q, r, s)$. Then the conjugation of z is just $\overline{z} = (a, -u)$ and the multiplication of quaternions can be expressed using the scalar and the wedge product of $\mathbb{R}^3$, which we will introduce in (4.125)

$$(a, u) \cdot (p, v) \;:=\; \Big(ap - \langle u, v\rangle,\; av + pu + u \wedge v\Big)$$

(1.39) Example: $(\diamondsuit)$
The next example is primarily concerned with ideals, not with rings, and should hence be postponed until you want to study an example of these. Now fix any (commutative) base ring $(R, +, \cdot)$ and a non-empty index set $I \neq \emptyset$. We have already introduced the ring $S := R^I = \mathcal{F}(I, R)$ of functions from I to R under the point-wise operations. For any subset $A \subseteq I$ we now obtain an ideal of S by letting

$$\mathfrak{v}(A) \;:=\; \{\, f \in S \mid \forall\, a \in A : f(a) = 0 \,\}$$

This is called the *vanishing ideal* if A. And for any two subsets $A, B \subseteq I$ it is easy to prove the identities

$$\mathfrak{v}(A)\,\mathfrak{v}(B) \;=\; \mathfrak{v}(A) \cap \mathfrak{v}(B) \;=\; \mathfrak{v}(A \cup B)$$

$$\mathfrak{v}(A) + \mathfrak{v}(B) \;=\; \mathfrak{v}(A \cap B)$$

Clearly (if I contains at least two distinct points) S contains zero-divisors. And if I is infinite then S is not a noetherian ring (if $(a_k) \subseteq I$ is a sequence ($k \in \mathbb{N}$) of points, then the ideals $\mathfrak{a}_k := \mathfrak{v}(I \setminus \{\, a_1, \ldots, a_k \,\})$ form a strictly ascending chain). In this sense S is a *really bad* ring. On the other hand this ring can easily be dealt with. Hence we recommend looking at this ring when searching for counterexamples in general ring theory. Finally if $A \subseteq I$ is a *finite* set then the radical of the ideal $\mathfrak{v}(A)$ is given to be

$$\sqrt{\mathfrak{v}(A)} \;=\; \{\, f \in S \mid \forall\, a \in A : f(a) \in \mathrm{NIL}(R) \,\}$$

Prob in the first equality $\mathfrak{v}(A) \cap \mathfrak{v}(B) = \mathfrak{v}(A \cup B)$ is clear and as $a = 0$ or $b = 0$ implies $ab = 0$ we also get the inclusion $\mathfrak{v}(A)\,\mathfrak{v}(B) \subseteq \mathfrak{v}(A) \cap \mathfrak{v}(B)$. Conversely suppose $h \in \mathfrak{v}(A \cup B)$ and let

$$f(a) := \begin{cases} 0 \text{ if } a \in A \\ 1 \text{ if } a \notin A \end{cases} \quad \text{and} \quad g(a) := \begin{cases} 0 \text{ if } a \in B \\ h(a) \text{ if } a \notin B \end{cases}$$

then $f \in \mathfrak{v}(A)$ and $g \in \mathfrak{v}(B)$ are clear and also $h = fg$. Thus we have proved $\mathfrak{v}(A \cup B) \subseteq \mathfrak{v}(A) \cap \mathfrak{v}(B)$ and thereby finished the first set of identities. In the second equality $\mathfrak{v}(A) + \mathfrak{v}(B) \subseteq \mathfrak{v}(A \cap B)$ is clear. And if we are conversely given any $h \in \mathfrak{v}(A \cap B)$ then let us define

$$f(a) := \begin{cases} 0 \text{ if } a \in A \\ h(a) \text{ if } a \notin A \end{cases} \quad \text{and} \quad g(a) := \begin{cases} h(a) \text{ if } a \in A \setminus B \\ 0 \text{ if } a \notin A \setminus B \end{cases}$$

thereby it is clear that $f \in \mathfrak{v}(A)$ and $g \in \mathfrak{v}(B)$ and an easy distinction of cases truly yields $h = f + g$. Now consider some $f \in S$ with $f^k \in \mathfrak{v}(A)$. That is for any $a \in A$ we get $f(a)^k = f^k(a) = 0$. In other words $f(a) \in \text{NIL}(R)$ for any $a \in A$. Conversely suppose that A is finte and that for any $a \in A$ we get $f(a) \in \text{NIL}(R)$. That is for any $a \in A$ there is some $k(a) \in \mathbb{N}$ such that $f^{k(a)}(a) = 0$. By taking $k := \max\{\, k(a) \mid a \in A \,\}$, we find $f^k \in \mathfrak{v}(A)$.

(1.40) Example:
Sometimes it is helpful to introduce *infinity* as a number. In this example we want to present how this can be done formally. The advantage of this construction is the formal ease by which infinity can be handled, the disadvantage is that the extensions loose may important algebraic properties.

(i) Arithmetic in $\overline{\mathbb{N}} := \mathbb{N} \cup \{\infty\}$: The set $\mathbb{N}$ of natural numbers is well-know. We now pick up a new symbol ∞, which we call *infinity*, and extend the natural order on $\mathbb{N}$ by declaring ∞ to be the maximal element of $\overline{\mathbb{N}}$. That is we define

$$\forall\, k \in \mathbb{N} \quad : \quad k < \infty$$

Also we can extend the usual addition $+$ and multiplication $\cdot$ on $\mathbb{N}$ by defining the addition and multiplication with any $a \in \overline{\mathbb{N}}$ to be

$$\begin{aligned} a + \infty &= \infty + a := \infty \\ a \cdot \infty &= \infty \cdot a := \begin{cases} \infty \text{ if } a \neq 0 \\ 0 \text{ if } a = 0 \end{cases} \end{aligned}$$

Thereby $\overline{\mathbb{N}}$ doesn't loose much properties of $\mathbb{N}$, still $(\overline{\mathbb{N}}, +)$ and $(\overline{\mathbb{N}}, \cdot)$ are commutative monoids, and we also retain the distributivity law between addition and multiplication (it is straightforward to check all this), i.e. for any a, b and $c \in \overline{\mathbb{N}}$ we get:

$$\begin{aligned} a \cdot (b + c) &= a \cdot b + a \cdot c \\ (a + b) \cdot c &= a \cdot c + b \cdot c \end{aligned}$$

The extended set $\overline{\mathbb{N}}$ is mainly used as an index set, if we want to handle finite cases of any finite size and the countably infinite case simultaneously. The next construction has a similar origin: Limits of sequences in $\mathbb{R}$ and volumes in space may be infinitely large. Hence in analysis and measure theory it is nice to have an easy way of dealing with the concept of infinity (without bothering with just how infinite exactly the object is, this is left to cardinality in set theory):

(ii) $(\diamondsuit)$ Arithmetic in $\overline{\mathbb{R}} := \mathbb{R} \cup \{\infty, -\infty\}$: The field $\mathbb{R}$ of real numbers has been introduced earlier in this section and is probably well-known to the reader already. Again we pick up a new symbol ∞, which we call *infinity*, and extend the natural order on $\mathbb{R}$ by making ∞ a maximal and $-\infty$ a minimal element:

$$\forall\, x \in \mathbb{R} \quad : \quad -\infty < x \text{ and } x < \infty$$

Again we extend the usual addition $+$ and multiplication $\cdot$ by defining the addition and multiplication with ∞ resp. with $-\infty$

$$\begin{array}{lcccl}
\forall\, a \in \mathbb{R} \cup \{\infty\} & : & a + \infty & = & \infty + a & := & \infty \\
\forall\, a \in \mathbb{R} \cup \{-\infty\} & : & a - \infty & = & -\infty + a & := & -\infty \\
\forall\, a \in \mathbb{R} \setminus \{0\} & : & a \cdot \infty & = & \infty \cdot a & := & \begin{cases} \infty \text{ if } a > 0 \\ -\infty \text{ if } a < 0 \end{cases} \\
\forall\, a \in \mathbb{R} \setminus \{0\} & : & a \cdot (-\infty) & = & (-\infty) \cdot a & := & \begin{cases} -\infty \text{ if } a > 0 \\ \infty \text{ if } a < 0 \end{cases}
\end{array}$$

Note that we did *neither* define $\infty + (-\infty)$ *nor* did we define $0 \cdot \infty$. Hence the set $\overline{\mathbb{R}}$ is no algebraic structure, as the operations $+$ and $\cdot$ are not fully defined! In fact any such definition would only result in contradictions: Suppose we had $\infty - \infty = 0$, as could have been expected, then since $1 \cdot \infty = \infty = 2 \cdot \infty$ we had $\infty = (2-1) \cdot \infty = \infty - \infty = 0$. Hence $\infty = 0$ wouldn't be a new element. In conclusion we just *cannot* define $\infty + (-\infty)$ or $0 \cdot \infty$, these terms have to be evaded - that is they may not occur within a computation. This is the one and only reason why computations with infinity have to be handled with great care.

The reason behind this is an analytic one: Take a look at the sequence $(n) = (0, 1, 2, 3, \dots) \subseteq \mathbb{R}$. We would like to write $(n) \to \infty$, as this sequence does not converge in $\mathbb{R}$ but increases strictly monotonous. Yet the difference of two determined divergent sequences can be just about anything: For any $a \in \mathbb{R}$ we get $(n + a) - (n) = (a) \to a$, whereas $(n^2) - (n) \to \infty$. Thus the result of $\infty - \infty$ is completely uncontrolled, as the limit of the difference of two sequences may be just about anything. The same is true for $\infty \cdot 0$. For example $(n) \cdot (1/n) = (1) \to 1$ converges trivially. Yet $(n^2) \cdot (1/n) = (n) \to \infty$ and even $(n) \cdot (1/n^2) = (1/n) \to 0$. Thus the limit can take any number or $\pm\infty$ again and therefore it makes no sense to fix a value for $\infty \cdot 0$.

1.5 First Concepts

Some Combinatorics

In the following proposition we want to establish some basic computational rules, that are valid in arbitrary rings. But in order to do this we first have to recall some elementary facts from combinatorics: First consider a set containing $1 \leq k \in \mathbb{N}$ elements. If we want to put a linear order to this set, we have to choose some first element. To do this there are k possibilities. We commence by choosing the second element - now having $(k-1)$ possibilities, and so on. Thus we end up with a number of linear orders on this set that equals $k!$ the *faculty* of k, that is defined to be

$$\begin{aligned} k! &:= \#\{\, \sigma : 1 \dots k \to 1 \dots k \mid \sigma \text{ bijective} \,\} \\ &= k \cdot (k-1) \cdots 2 \cdot 1 \end{aligned}$$

If $k = 0$ we specifically define $0! := 1$. Next we consider a set containing $n \in \mathbb{N}$ elements. If we want to select a subset I of precisely $k \in 0 \dots n$ elements we have to start by choosing a first element (n possibilities). In the next step we may only choose from $(n-1)$ elements and so on. We end with the k-th choice, for which we still have $n-k+1$ numbers to choose from, left. But as a subset does not depend on the order of its elements, we still have to divide by $k!$ - the number of linear orders on I. Altogether we end up with

$$\begin{aligned} \binom{n}{k} &:= \#\{\, I \subseteq 1 \dots n \mid \#I = k \,\} \\ &= \frac{n}{k} \cdot \frac{n-1}{k-1} \cdots \frac{n-k+1}{1} \\ &= \frac{n!}{k!\,(n-k)!} \end{aligned}$$

Note that this definition also works out in the case $n = 0$ and $k = 0$ (in which the *binomial coefficient* $(n\ k)$ equals one. That is we get $(n\ 0) = 1 = (n\ n)$. Also it is clear (by looking at the formular above), that $(n\ k)$ is just the same, as $(n\ n-k)$. This makes sense: To gather I you can either pick out the elements of I or take away all $k \notin I$, so that only I is left. Furthermore the binomial coefficents satisfy a famous recursion formula, which is the reason behind *Pascal's triangle*

$$\begin{aligned} \binom{n}{n-k} &= \binom{n}{k} \\ \binom{n+1}{k} &= \binom{n}{k} + \binom{n}{k-1} \end{aligned}$$

Finally consider some *multi-index* $\alpha = (\alpha_1, \dots, \alpha_k) \in \mathbb{N}^k$. Then it will be useful to introduce the following notations (where the latter will only be used, for $n := |\alpha|$)

$$\begin{aligned} |\alpha| &:= \alpha_1 + \cdots + \alpha_k \\ \alpha! &:= (\alpha_1!) \cdot \ldots \cdot (\alpha_k!) \\ \binom{n}{\alpha} &:= \frac{n!}{\alpha!} \end{aligned}$$

(1.41) Proposition: (viz. 725)

- Let $(R,+,\cdot)$ be any semi-ring and consider arbitrary elements $a, b \in R$ of R. Then the following computational rules hold true

$$\begin{aligned} 0 &= -0 \\ a0 &= 0 = 0a \\ (-a)b &= -(ab) = a(-b) \\ (-a)(-b) &= ab \end{aligned}$$

- If now $a_1, \ldots, a_m \in R$ and $b_1, \ldots, n_n \in R$ are finitely many, arbitrary elements of R, then we also obtain the *general rule of distributivity*

$$\left(\sum_{i=1}^{m} a_i\right)\left(\sum_{j=1}^{n} b_j\right) = \sum_{i=1}^{m}\sum_{j=1}^{n} a_i b_j$$

 And if $J(1), \ldots, J(n)$ are finite index sets (where $1 \leq n \in \mathbb{N}$) and $a(i,j) \in R$ for any $i \in 1 \ldots n$, $j \in J(i)$ then we let $J := J(1) \times \cdots \times J(n)$ (and $j = (j_1, \ldots, j_n) \in J$) and thereby obtain

$$\prod_{i=1}^{n} \sum_{j_i \in J(i)} a(i,j_i) = \sum_{j \in J} \prod_{i=1}^{n} a(i,j_i)$$

- Now suppose $(R,+,\cdot)$ is a ring, $n \in \mathbb{N}$ and $a, b \in R$ are elements, that mutually commute (that is $ab = ba$), then we get the *binomial rule*

$$(a+b)^n = \sum_{k=0}^{n} \binom{n}{k} a^k b^{n-k}$$

 And if $(R,+,\cdot)$ even is a commutative ring $a_1, \ldots, a_k \in R$ are finitely many elements and $n \in \mathbb{N}$ then we even get the following *polynomial rule*, where the sum runs over all multi-indexes $\alpha \in \mathbb{N}^k$ that satisfy $|\alpha| = \alpha_1 + \cdots + \alpha_k = n$. And a^α abbreviates $a^\alpha := (a_1)^{\alpha_1} \cdots (a_k)^{\alpha_k}$

$$(a_1 + \cdots + a_k)^n = \sum_{|\alpha|=n} \binom{n}{\alpha} a^\alpha$$

(1.42) Remark:
Thus there are many computational rules that hold true for arbitrary rings. However there also are some exceptions to integer (or even real) arithmetic. E.g. we are *not* allowed to deduce $a = 0$ or $b = 0$ from $ab = 0$. As a counterexample regard $a = 2 + 6\mathbb{Z}$ and $b = 3 + 6\mathbb{Z}$ in $\mathbb{Z}_6$. A special case of this is the following: We may *not* deduce $a = 0$ from $a = -a$. As a counterexample regard $a = 1 + 2\mathbb{Z}$ in $\mathbb{Z}_2$.

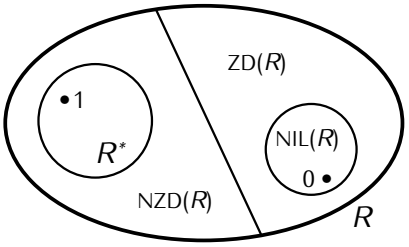
(1.43) Remark:
An exceptional role pays the **zero-ring** $R = \{0\}$, it clearly is a commutative ring (under the trivial operations) that would even satisfy condition (F). But it is the only ring in which $0 = 1$. More formally we've got the equivalence

$$R = \{0\} \quad \Longleftrightarrow \quad 0 = 1$$

[as $\Longrightarrow$ is clear and in the converse direction regard $a = 1a = 0a = 0$]. This equality $0 = 1$ will lead to some peculiarities however. This is precisely why we required $0 \neq 1$ for skew-fields and fields. And several theorems will require R to be not the zero-ring, which we will abbreviate by $R \neq 0$.

(1.44) Remark: (viz. 727)
As a neat little application of the binomial rule let us present a generalization of the recursion formula for the binomial coefficients: Regarding the expression $(x+y)^n = (x+y)^k(x+y)^{n-k}$ in $\mathbb{Z}[x,y]$ and comparing coefficients, one easily verifies, that for any $k, n \in \mathbb{N}$ and any $r \in 0 \ldots k$ we get

$$\sum_{i=0}^{r} \binom{k}{i}\binom{n-k}{r-i} \;=\; \binom{n}{r}$$



(1.45) Definition: (viz. 728)
Let $(R,+,\cdot)$ be any semi-ring and $b \in R$ be any element of R. Then we define the sets $\text{ZD}(R)$ of **zero-divisors**, $\text{NZD}(R)$ of **non-zero-divisors**, the **nil-radical** $\text{NIL}(R)$ and the **annihilator** $\text{ann}(b)$ of b to be

$$\begin{aligned}
\text{ZD}(R) &:= \{\, a \in R \mid \exists\, b \in R \;:\; b \neq 0 \text{ and } ab = 0 \,\} \\
\text{NZD}(R) &:= \{\, a \in R \mid \forall\, b \in R \;:\; ab = 0 \implies b = 0 \,\} \\
\text{NIL}(R) &:= \left\{\, a \in R \mid \exists\, k \in \mathbb{N} \;:\; a^k = 0 \,\right\} \\
\text{ann}(b) &:= \{\, a \in R \mid ab = 0 \,\}
\end{aligned}$$

We sometimes also write $\text{ann}_R(b)$ instead of $\text{ann}(b)$ to emphasize the ring $\text{ann}_R(b) \subseteq R$ is taken in. An element $a \in \text{NIL}(R)$ contained in the nil-radical is also said to be *nilpotent*. If now R even is a ring we define the set R^* of **units** (or *invertible* elements) and the set $R^\bullet$ of *relevant* elements of R

$$\begin{aligned}
R^* &:= \{\, a \in R \mid \exists\, b \in R : ab = 1 = ba \,\} \\
R^\bullet &:= R \setminus \left(\{0\} \cup R^*\right)
\end{aligned}$$

The following Venn-diagramm illustrates the situation how these sets relate to each other. Algebraically this will be formulated and proved in (1.47)

And $(R,+,\cdot)$ is said to be **integral**, iff it does not contain any non-zero zero-divisors, that is iff it satisfies one of the following five equivalent statements

(a) $\text{ZD}(R) \;=\; \{0\}$

(b) for any a, b and $c \in R$ such that $a \neq 0$ we get $ab = ac \implies b = c$

(b') for any a, b and $c \in R$ such that $c \neq 0$ we get $ac = bc \implies a = b$

(c) for any a, $b \in R$ such that $a \neq 0$ we get $ab = a \implies b = 1$

(c') for any a, $b \in R$ such that $b \neq 0$ we get $ab = b \implies a = 1$

Now $(R,+,\cdot)$ is said to be an **integral domain**, iff it is a commutative ring that also is non-zero $R \neq 0$ and satisfies $\text{ZD}(R) = \{0\}$.

(1.46) Remark:

- Consider any semi-ring $(R,+,\cdot)$, two elements a, $b \in R$ and a non-zero-divisor $n \in \text{NZD}(R)$. Then $a = b$ is equivalent to $na = nb$, formally

$$a = b \quad\iff\quad na = nb$$

 Prob the direction " $\implies$ " is clear, and if $na = nb$ then $n(a-b) = 0$ which implies $a - b = 0$ (and hence $a = b$), since n is a non-zero-divisor.

- Let $(R,+,\cdot)$ be a ring, $a \in R$ be any element and $n \in \text{NZD}(R)$ be a non-zero-divisor. Then we obtain the implication

$$na = 1 \quad\implies\quad an = 1$$

 Prob since $n(an) = (na)n = n$ and hence $n(an-1) = 0$. But as n is a non-zero-divisor this implies $an - 1 = 0$ and hence $an = 1$.

- Consider a commutative ring $(R,+,\cdot)$ and finitely many elements $a_1, \ldots, a_n \in R$. Let $u \in R$ be the product of these a_i, that is $u := a_1 \ldots a_n \in R$, then we obtain the implication

$$u \in R^* \quad\implies\quad a_1, \ldots, a_n \in R^*$$

 Prob choose any $j \in 1 \ldots n$ and let $\widehat{a}_j := \prod_{i \neq i} a_i$, e.g. $\widehat{a}_1 := a_2 \ldots a_n$. Then by construction we get $1 = u^{-1}(a_1 \ldots a_n) = (u^{-1}\widehat{a}_j)a_j$. And hence we see $a_j \in R^*$ with inverse $a_j^{-1} = u^{-1}\widehat{a}_j$.

- ($\diamondsuit$) For an R-module M over a ring $(R,+,\cdot)$ we will generalize this concept in the following way: We will define the set of *zero-divisors* of M to be the set of all $a \in R$ that turn $x \in M$ with $x \neq 0$ into $ax = 0$ under scalar multiplication

$$\text{ZD}_R(M) \;:=\; \{\, a \in R \mid \exists\, x \in M \,:\, x \neq 0 \text{ and } ax = 0 \,\}$$

 Then $\text{ZD}_R(R) = \text{ZD}(R)$ if we consider R as an R-module. And if $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is an ideal, if we consider $M = R/\mathfrak{a}$ as an R-module, we find $\text{ZD}_R(R/\mathfrak{a}) = \{\, a \in R \mid \exists\, b \in R\; b \notin \mathfrak{a} \text{ and } ab \in \mathfrak{a} \,\}$ such that $\text{ZD}(R/\mathfrak{a}) = \{\, a + \mathfrak{a} \mid a \in \text{ZD}_R(R/\mathfrak{a}) \,\}$. Refer to (2.89) for more comments on this.

- If $(R,+,\cdot)$ is a skew-field, then R already is integral (i.e. $\mathrm{zd}(R)=\{0\}$) and allows division: That is any two elements $a, b \in R$ with $a \neq 0$ are connectet via multiplication, in the following sense:

$$\exists!\, u,v \in R \;\; : \;\; ua = b \;\text{ and }\; av = b$$

 Prob since $a \neq 0$ and R is a skew-field there is some $i \in R$ such that $ai = 1 = ia$. Now suppose $ab = 0$, then $b = (ia)b = i(ab) = 0$ and hence $a \in \mathrm{nzd}(R)$. This proves $\mathrm{zd}(R) = \{0\}$. Again, given $a, b \in R$ with $a \neq 0$ choose $i \in R$ such that $ai = 1 = ia$ and let $u := bi$ and $v := ib$. Then $ua = (bi)a = b(ia) = b$ and $av = a(ib) = (ai)b = b$. Now suppose $u', v' \in R$ with $ua = b = u'a$ and $av = b = av'$. Then $a(v - v') = 0$ but as $a \neq 0$ we have seen that this implies $v - v' = 0$ and hence $v = v'$. Likewise $(u - u')a = 0$ implies $u = u'$.

The sets of zero-divisors $\mathrm{zd}(R)$ and of relevant elements $R^\bullet$ rarely carry any noteworthy algebraic structure. Yet the units R^* form a group, the non-zero-divisors $\mathrm{nzd}(R)$ are multiplicatively closed, the nil-radical $\mathrm{nil}(R)$ is an (even perfect) ideal of R and the annihilator $\mathrm{ann}(b)$ of some element $b \in R$ is a sub-module. Though we have not introduced these structures yet, we would like to present a formal proposition (and proof) of these facts already.

(1.47) Proposition: (viz. 728) $(\diamondsuit)$

(i) Let $(R,+,\cdot)$ be any semi-ring, then R is the disjoint union of its zero-divisors and non-zero divisors

$$\mathrm{nzd}(R) \;\; = \;\; R \setminus \mathrm{zd}(R)$$

(ii) In any non-zero ($R \neq 0$) ring $(R,+,\cdot)$ the nilradical is contained in the set of zero-divisors. And the zero-divisors are likewise contained in non-units of R. That is we've got the inclusions

$$\mathrm{nil}(R) \;\; \subseteq \;\; \mathrm{zd}(R) \;\; \subseteq \;\; R \setminus R^*$$

(iii) Let $(R,+,\cdot)$ be any semi-ring, then the set $\mathrm{nzd}(R) \subseteq R$ of non-zero-divisors of R is multiplicatively closed, that is we get it satisfies the following two properties

$$1 \;\; \in \;\; \mathrm{nzd}(R)$$

$$a, b \in \mathrm{nzd}(R) \;\; \Longrightarrow \;\; ab \in \mathrm{nzd}(R)$$

(iv) Consider any ring $(R,+,\cdot)$, then $(R^*,\cdot)$ is a group (where $\cdot$ denotes the multiplication of R), called the *multiplicative group* of R.

(v) If $(R,+,\cdot)$ is any ring then R is a skew-field if and only if the multiplicative group of R consists precisely of the non-zero elements. That is we find the equivalence, of

$$R \text{ skew-field} \;\; \Longleftrightarrow \;\; R^* = R \setminus \{0\}$$

(vi) If $(R,+,\cdot)$ is a commutative ring, then the nil-radical is an ideal of R. Symbolically: $\mathrm{nil}(R) \trianglelefteq_{\mathrm{i}} R$.

(vii) Let $(R,+,\cdot)$ be any ring and $b \in R$ an element of R. Then the annihilator $\mathrm{ann}(b)$ is a left-ideal (i.e. a sub-module) of R. Symbolically $\mathrm{ann}(b) \leq_{\mathsf{m}} R$.

(viii) Let $(R,+,\cdot)$ be a commutative ring and $u \in R^*$ be a unit of R. Then $u + \mathrm{NIL}(R) \subseteq R^*$. To be precise, if $a \in R$ with $a^n = 0$ then we get

$$(u+a)^{-1} \;=\; \sum_{k=0}^{n-1} (-1)^k a^k u^{-k-1}$$

(ix) If $(R,+,\cdot)$ is an integral domain, $F := \mathrm{QUOT}(R)$ its quotient field and $E \leq_{\mathsf{f}} F$ is a sub-field of F, then we get the equivalence of

$$R \subseteq E \iff E = F$$

(1.48) Example:
We present a somewhat advanced example that builds upon some results from linear algebra. Let us regard the ring $R := \mathrm{mat}_2(\mathbb{Z})$ of (2×2)-matrices over the integers. We will need the notions of the *determinant*, *trace* and *adjoint matrix* of a matrix

$$\begin{aligned}
\det \begin{pmatrix} a & b \\ c & d \end{pmatrix} &:= ad - bc \in \mathbb{Z} \\
\mathrm{tr} \begin{pmatrix} a & b \\ c & d \end{pmatrix} &:= a + d \in \mathbb{Z} \\
\begin{pmatrix} a & b \\ c & d \end{pmatrix}^\sharp &:= \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}
\end{aligned}$$

Then we can explicitly determine which matrices are *invertible* (that is units), which are zero-divisors and which are nil-potent. We find

$$\begin{aligned}
R^* &= \{\, A \in R \mid \det A = \pm 1 \,\} \\
\mathrm{ZD}(R) &= \{\, A \in R \mid \det A = 0 \,\} \\
\mathrm{NIL}(R) &= \{\, A \in R \mid \det A = \mathrm{tr} A = 0 \,\}
\end{aligned}$$

($\diamondsuit$) Prob first note that an easy computation yields $AA^\sharp = (\det A)\mathbb{1} = A^\sharp A$. Hence if A is invertible, then $A^{-1} = (\det A)^{-1} A^\sharp$. Thus A is invertible if and only if $\det A$ is a unit (in $\mathbb{Z}$), but as the units of $\mathbb{Z}$ are given to be $\mathbb{Z}^* = \{\pm 1\}$ this already is the first identity. For the second identity we begin with $\det A = 0$. Then $AA^\sharp = (\det A)\mathbb{1} = 0$ and hence A is a zero-divisor. Conversely suppose that $A \in \mathrm{ZD}(R)$ is a zero-divisor, then $AB = 0$ for some $B \neq 0$ and hence $(\det A)B = A^\sharp AB = 0$. But as B is non-zero this implies $\det A = 0$. Finally if $\det A = 0$ then an easy computation shows $A^2 = (\mathrm{tr} A)A$, thus if also $\mathrm{tr} A = 0$ then $A^2 = 0$ and hence $A \in \mathrm{NIL}(R)$. And if conversely $A \in \mathrm{NIL}(R) \subseteq \mathrm{ZD}(R)$, then $\det A = 0$ and hence (by induction on n) $A^n = (\mathrm{tr} A)^{n-1} A$. As A is nilpotent there is some $1 \leq n \in \mathbb{N}$ such that $0 = A^n = (\mathrm{tr} A)^{n-1} A$ and hence $\mathrm{tr} A \in \mathrm{NIL}(\mathbb{Z}) = \{0\}$.

($\diamondsuit$) The following proposition is a classical topic, called *partial fraction decomposition* of rational fractions $f/g \in E(t)$ over some base field E. It only is loosely connected to the rest of this text and uses some notions, that probably are known to the reader, but - from a formal point of view - will be introduced in chapter 7 only. So you might want to skip it, for now.

(1.49) Proposition: (viz. 808)
Let $(E,+,\cdot)$ be any field, consider two polynomials f and $g \in E[t]$ and denote the quotient field of $E[t]$ (called the field of *rational fractions*) by $E(t)$ [refer to (1.31) for a construction]

(i) If $x \in E$ is not a root $g(x) \neq 0$ of g, then there are a constant $c \in E$ and a polynomial $h \in E[t]$ such that for any $k \in \mathbb{N}$ the following equality in $E(t)$ holds true

$$\frac{f(t)}{(t-x)^k g(t)} \;=\; \frac{c}{(t-x)^k} + \frac{h(t)}{(t-x)^{k-1} g(t)}$$

Thereby the constant c and the polynomial h are uniquely determined, to be the following [note that $t-x$ divides $f(t)-cg(t)$ such that h is a polynomial not only a rational fraction]

$$c \;=\; f(x)g(x)^{-1} \quad \text{and} \quad h(t) \;=\; \frac{f(t)-cg(t)}{t-x}$$

(ii) Suppose that g *splits* over E, that is $g \neq 0$ and there are pairwise distinct *roots* $x_i \in E$ and powers $1 \leq k_i \in \mathbb{N}$, such that letting $b := \mathrm{lc}(g)$ we can write g in the form

$$g(t) \;=\; b\,(t-x_1)^{k_1} \ldots (t-x_r)^{k_r}$$

Further assume that f is of lesser degree $\deg(f) < \deg(g)$ than g, then there are uniquely determined coefficients $c_{i,j} \in E$ (where $i \in 1 \ldots r$ and $j \in 1 \ldots k_i$) such that in $E(t)$ we get

$$\frac{f(t)}{g(t)} \;=\; \sum_{i=1}^{r} \sum_{j=1}^{k_i} \frac{c_{i,j}}{(t-x_i)^j}$$

Nota let $n := \deg(g)$, then clearly $\{\, f(t)/g(t) \mid f \in E[t], \deg(f) < n \,\} \subseteq E(t)$ is an E-vector space. And its canonical basis is given to be $\{\, x^k/g(t) \mid k \in 0 \ldots n \,\}$. Now (ii) can be reformulated, as: Also $\{\, 1/(t-x_i)^j \mid i \in 1 \ldots r, j \in 1 \ldots k_i \,\}$ is a basis of this vector space.

Nota if $\deg(f) \geq \deg(g)$ we may use division with remainder - refer to (2.67) - first, to write $f(t)$ in the form $f = qg + r$ for some polynomials $q(t)$, $r(t) \in E[t]$ with $\deg(r) < \deg(g)$. Then $f/g = q + r/g$ and we may apply (ii) here to r/g to finally get

$$\frac{f(t)}{g(t)} \;=\; q(t) + \sum_{i=1}^{r} \sum_{j=1}^{k_i} \frac{c_{i,j}}{(t-x_i)^j}$$

1.6 Ideals

(1.50) Definition:

- Let $(R,+,\cdot)$ be a semi-ring and $P \subseteq R$ a subset. Then P is said to be a **sub-semi-ring** of R (abbreviated by $P \leq_s R$), iff for any $a, b \in R$ we get

 (1) $0 \in P$

 (2) $a, b \in P \implies a+b \in P$

 (3) $a \in P \implies -a \in P$

 (4) $a, b \in P \implies ab \in P$

- And if $(R,+,\cdot)$ is a ring having the unit element 1, then a subset $P \subseteq R$ is called a **sub-ring** of R (abbreviated by $P \leq_r R$), iff we have

 (S) $P \leq_s R$

 (5) $1 \in P$

- Finally if $(R,+,\cdot)$ even is a (skew)field, then a subset $P \subseteq R$ is said to be a **sub-(skew)field** of R (abbreviated $P \leq_f R$), iff for any $a \in R$ we get

 (R) $P \leq_r R$

 (6) $0 \neq a \in P \implies a^{-1} \in P$

- Let $(R,+,\cdot)$ be a semi-ring again, then a subset $\mathfrak{a} \subseteq R$ is said to be a **left-ideal** (or **sub-module**) of R (abbreviated by $\mathfrak{a} \leq_m R$), iff for any $a, b \in R$ we get

 (1) $0 \in \mathfrak{a}$

 (2) $a, b \in \mathfrak{a} \implies a+b \in \mathfrak{a}$

 (3) $a \in \mathfrak{a} \implies -a \in \mathfrak{a}$

 (4) $a \in \mathfrak{a}, b \in R \implies ba \in \mathfrak{a}$

 The subset $\mathfrak{a} \subseteq R$ is said to be an **ideal** of R (abbreviated by $\mathfrak{a} \trianglelefteq_i R$), iff for any $a, b \in R$ we get

 (M) $\mathfrak{a} \leq_m R$

 (5) $a \in \mathfrak{a}, b \in R \implies ab \in \mathfrak{a}$

- We will sometimes use the set of all sub-rings (of a ring R), the set of all sub(skew)fields (of a (skew)field R), resp. the set of all (left-)ideals (of a semi-ring R) - these will be denoted, by

$$\begin{aligned}
\mathrm{Subr}(R) &:= \{ P \subseteq R \mid P \leq_r R \} \\
\mathrm{Subf}(R) &:= \{ P \subseteq R \mid P \leq_f R \} \\
\mathrm{Subm}(R) &:= \{ \mathfrak{a} \subseteq R \mid \mathfrak{a} \leq_m R \} \\
\mathrm{Ideal}(R) &:= \{ \mathfrak{a} \subseteq R \mid \mathfrak{a} \trianglelefteq_i R \}
\end{aligned}$$

(1.51) Remark:

- Consider any semi-ring $(R,+,\cdot)$ and an arbitrary sub-semi-ring $P \leq_s R$ of R. Then we would like to emphasize, that the notion of a sub-semi-ring was defined in such a way that the addition $+$ and multiplication $\cdot$ of R induces the like operations on P

$$\begin{aligned} +\big|_P &: P \times P \to P \;:\; (a,b) \mapsto a+b \\ \cdot\big|_P &: P \times P \to P \;:\; (a,b) \mapsto ab \end{aligned}$$

 And thereby $(P, +\big|_P, \cdot\big|_P)$ becomes a semi-ring again (clearly all the properties of such are inherited from R). And in complete analogy we find that sub-rings of rings are rings again and sub(skew)fields of (skew)fields are (skew)fields again, under the induced operations.

 Nota as $+\big|_P$ and $\cdot\big|_P$ are just restrictions of the respective functions $+$ and $\cdot$ on R, we will not distinguish between $+\big|_P$ and $+$ respectively between $\cdot\big|_P$ and $\cdot$. That is we will speak of the semi-ring $(P,+,\cdot)$, where $+$ and $\cdot$ here are understood to be the restricted operations $+\big|_P$ and $\cdot\big|_P$ acting on $P \times P$, respectively.

- Beware: It is possible, that a sub-semi-ring $P \leq_s R$ is a ring $(P,+,\cdot)$ under the induced operations, but *no* sub-ring of R. E.g. consider $R := \mathbb{Z} \times \mathbb{Z}$ under the point-wise operations and $P := \mathbb{Z} \times \{0\} \subseteq R$. Then $P \leq_s R$ is a sub-semi-ring. But it is no sub-ring, as the unit element $(1,1) \in R$ of R is *not* contained $(1,1) \notin P$ in P. Nevertheless P has a unit-element, namely $(1,0) \in P$ and hence is a ring in itself.

- If $(R,+,\cdot)$ is a *ring*, then property (3) of left-ideals is redundant, it already follows from property (4) by letting $b := -1$. We only require (3) in case of a *semi*-ring R.

- Let $(R,+,\cdot)$ be a semi-ring, then trivially any left-ideal $\mathfrak{a}$ of R already is a sub-semi-ring. Formally put for any subset $\mathfrak{a} \subseteq R$ we get the implication

$$\mathfrak{a} \leq_m R \implies \mathfrak{a} \leq_s R$$

- Consider a commutative semi-ring $(R,+,\cdot)$, then the property (4) of left-ideals already implies property (5) of ideals, due to commutativity. That is in a *commutative* semi-ring R we find the following equivalence for any subset $\mathfrak{a} \subseteq R$

$$\mathfrak{a} \leq_m R \iff \mathfrak{a} \trianglelefteq_i R$$

- Now let $(R,+,\cdot)$ be any ring and let $\mathfrak{a} \leq_m R$ be a left-ideal of R. Then clearly clearly $1 \in \mathfrak{a}$ is just the same, as $a = R$. We will call $\mathfrak{a}$ a **proper** left-ideal, iff $\mathfrak{a} \neq R$. Formally put

$$\mathfrak{a} = R \iff 1 \in \mathfrak{a}$$

 Prob " $\implies$ " is clear, as $1 \in R$ and if conversely $1 \in \mathfrak{a}$ then due to property (4) we have $a = a1 \in \mathfrak{a}$ for any $a \in R$. Hence $R \subseteq \mathfrak{a} \subseteq R$, such that $\mathfrak{a} = R$.

- Consider any semi-ring $(R, +, \cdot)$ and some element $a \in R$. Then we obtain a left-ideal Ra in R (called the **principal ideal** of a), by letting

$$Ra \;:=\; \{\, ba \mid b \in R \,\} \quad \leq_{\mathfrak{m}} \quad R$$

 Prob clearly $0 = 0a \in Ra$ and if ba and $ca \in R$, then we see that $ba + ca = (b + c)a \in Ra$ and $-(ba) = (-b)a \in Ra$. Finally we have $c(ba) = (cb)a \in Ra$ for any $c \in R$.

- In a *commutative* semi-ring $(R, +, \cdot)$ (where $a \in R$ again) we clearly get $Ra = aR$, where the latter is defined to be the following subset, which already is an ideal of R

$$aR \;:=\; \{\, ab \mid b \in R \,\} \quad \trianglelefteq_{\mathfrak{i}} \quad R$$

 And as R is commutative $Ra = aR$ already is an ideal of R. And it is customary to take to aR instead of Ra, in this case. We will later see (cf. section 2.7), that $\mathbb{Z}$ is a PID - that is *every* ideal of $\mathbb{Z}$ is of the form $a\mathbb{Z}$ for some $a \in \mathbb{Z}$. Formally that is

$$\mathrm{Ideal}(\mathbb{Z}) \;=\; \{\, a\mathbb{Z} \mid a \in \mathbb{Z} \,\}$$

- In any semi-ring $(R, +, \cdot)$ we always have the *trivial* ideals $\{0\}$ and $R \trianglelefteq_{\mathfrak{i}} R$. If R is a skew-field, then these even are the only ideals of R, that is

$$R \text{ skew-field} \quad \Longrightarrow \quad \mathrm{Subm}(R) = \{\, \{0\}, R \,\}$$

 Nota it is customary to denote the ideal $\{0\}$ by 0 again. This is an abuse of notation, as 0 also is the zero-element of R. Do not mix these up and beware $0 \in 0$, as hereby the first is $0 \in R$ and the second is $0 \trianglelefteq_{\mathfrak{i}} R$. Prob let $\mathfrak{a} \leq_{\mathfrak{m}} R$ be any left-ideal of R, if there is some $0 \neq a \in \mathfrak{a}$ then $a^{-1} \in R$ and hence $1 = a^{-1}a \in \mathfrak{a}$. And from this we get $\mathfrak{a} = R$, by the reasoning above.

- Now consider some non-zero ($R \neq 0$) commutative ring $(R, +, \cdot)$. Then we even get: R is a field if and only if the only ideals of R are the trivial ones. That is equivalent are

$$R \text{ field} \quad \Longleftrightarrow \quad \mathrm{Ideal}(R) = \{\, \{0\}, R \,\}$$

 Prob " $\Longrightarrow$ " has already been shown above, for " $\Longleftarrow$ " regard any $0 \neq a \in R$, then $aR \trianglelefteq_{\mathfrak{i}} R$ is an ideal of R. But as $aR \neq \{0\}$ this only leaves $aR = R$ and hence there is some $i \in R$ such that $ai = 1$, which means $i = a^{-1}$. Altogether R is a field.

- We could have introduced a dual notion of a left-ideal - a so-called *right-ideal*. This is a subset $\mathfrak{a} \subseteq R$ such that the properties (1), (2), (3) and (5) of (left-)ideals hold true. That is we have replaced (4) by (5). However this would lead to a completely analogous theory. Also refer to section 3.1 for a little more comments on this.

(1.52) Lemma: (viz. 730)
For the moment being let $\star$ abbreviate any one of the words *semi-ring*, *ring*, *skew-field* or *field* and let $(R,+,\cdot)$ be a $\star$. Further consider an arbitrary family (where $i \in I \neq \emptyset$) $P_i \subseteq R$ of sub-$\star$s of R. Then the intersection P_i is a sub-$\star$ of R again

$$\bigcap_{i\in I} P_i \quad \subseteq \quad R \quad \text{is a sub-}\star$$

Likewise let us abbreviate by $\star$ the word *left-ideal* or the word *ideal*. Now suppose $(R,+,\cdot)$ is a semi-ring and consider an arbitrary family (where $i \in I \neq \emptyset$) $\mathfrak{a}_i \subseteq R$ of $\star$s of R. Then the intersection of the $\mathfrak{a}_i$ is a $\star$ of R again

$$\bigcap_{i\in I} \mathfrak{a}_i \quad \subseteq \quad R \quad \text{is a } \star$$

The proof of this lemma is an easy, straightforward verification of the properties of a (sub-)$\star$ in all the separate cases. But though this is most easy it has far-reaching consequences. Whenever we are given a subset $X \subseteq R$ we may consider the smallest $\star$ of R containing X. Just take the intersection over all $\star$s containing X (this is possible since at least R is a $\star$ with $X \subseteq R$). The following definition formalizes this idea. And it is not much of a surprise, that this smallest $\star$ then can be described explicitly by taking all the elements of X and performing all the operations allowed for a $\star$.

(1.53) Definition:
Let now $(R,+,\cdot)$ be a semi-ring and consider an arbitrary subset $X \subseteq R$ of R. Then the above lemma allows us to introduce the sub-semi-ring, left-ideal, resp. ideal **generated** by X to be the intersection of all such containing X

$$\begin{aligned}
\langle X\rangle_{\mathsf{s}} &:= \bigcap\{\, P \subseteq R \mid X \subseteq P \leq_{\mathsf{s}} R\,\}\\
\langle X\rangle_{\mathsf{m}} &:= \bigcap\{\, \mathfrak{a} \subseteq R \mid X \subseteq \mathfrak{a} \leq_{\mathsf{m}} R\,\}\\
\langle X\rangle_{\mathsf{i}} &:= \bigcap\{\, \mathfrak{a} \subseteq R \mid X \subseteq \mathfrak{a} \trianglelefteq_{\mathsf{i}} R\,\}
\end{aligned}$$

Likewise if R even is a ring (or (skew)field) we may define the sub-ring (or sub-(skew)field respectively) to be the intersection of all such containing X

$$\begin{aligned}
\langle X\rangle_{\mathsf{r}} &:= \bigcap\{\, P \subseteq R \mid X \subseteq P \leq_{\mathsf{r}} R\,\}\\
\langle X\rangle_{\mathsf{f}} &:= \bigcap\{\, P \subseteq R \mid X \subseteq P \leq_{\mathsf{f}} R\,\}
\end{aligned}$$

Nota in case that there may be any doubt concerning the semi-ring X is contained in (e.g. $X \subseteq R \subseteq S$) we emphasize the semi-ring R used in this construction by writing $\langle X \subseteq R\rangle_{\mathsf{i}}$ or $\langle X\rangle_{\mathsf{i}} \trianglelefteq_{\mathsf{i}} R$ or even $R\langle X\rangle_{\mathsf{i}}$.

(1.54) Remark:
In case $X = \emptyset$ it is clear that $\{0\}$ is an ideal containing X. And as 0 is contained in any other ideal (even sub-semiring) of R we find

$$\langle\emptyset\rangle_{\mathsf{s}} \;=\; \langle\emptyset\rangle_{\mathsf{m}} \;=\; \langle\emptyset\rangle_{\mathsf{i}} \;=\; \{0\}$$

The case of the sub-ring resp. sub(skew)field generated by $\emptyset$ usually is less trivial however. Let us regard the case $R = \mathbb{Q}$ for example. As any sub-ring has to contain 1 and allow sums and negatives, we find that $\mathbb{Z} = \langle\emptyset\rangle_{\mathsf{r}} \subseteq \mathbb{Q}$. And as a sub-field even allows to take inverses we find $\mathbb{Q} = \langle\emptyset\rangle_{\mathsf{f}} \subseteq \mathbb{Q}$. However in $\mathbb{C}$ we also get $\mathbb{Q} = \langle\emptyset\rangle_{\mathsf{f}} \subseteq \mathbb{C}$ only. Hence the intersection of all sub-rings resp. all sub(skew)fields deserves a special name, it is called the **prime-ring** resp. **prime-(skew-)field** of R

$$\begin{aligned}\langle\emptyset\rangle_{\mathsf{r}} &= \bigcap\{\, P \subseteq R \mid P \leq_{\mathsf{r}} R \,\}\\ \langle\emptyset\rangle_{\mathsf{f}} &= \bigcap\{\, P \subseteq R \mid P \leq_{\mathsf{f}} R \,\}\end{aligned}$$

(1.55) Proposition: (viz. 730)
Consider a ring $(R, +, \cdot)$ and a non-empty subset $\emptyset \neq X \subseteq R$. Then we can give an explicit description of the (left)-ideal generated by X. It turns out, these are given to be

$$\langle X\rangle_{\mathsf{m}} = \left\{ \sum_{i=1}^{n} a_i x_i \;\middle|\; 1 \leq n \in \mathbb{N},\ x_i \in X,\ a_i \in R \right\}$$

$$\langle X\rangle_{\mathsf{i}} = \left\{ \sum_{i=1}^{n} a_i x_i b_i \;\middle|\; 1 \leq n \in \mathbb{N},\ x_i \in X,\ a_i, b_i \in R \right\}$$

Suppose R is any semi-ring and denote $\pm X := \{\, x \mid x \in X \,\} \cup \{\, -x \mid x \in X \,\}$ then we can also give an explicit description of the sub-semiring of R generated by X (and if R is a ring also of the sub-ring of R generated by X), which are given to be

$$\langle X\rangle_{\mathsf{s}} = \left\{ \sum_{i=1}^{m} \prod_{j=1}^{n} x_{i,j} \;\middle|\; 1 \leq m, n \in \mathbb{N},\ x_{i,j} \in \pm X \right\}$$

$$\langle X\rangle_{\mathsf{r}} = \langle X \cup \{\, 1 \,\}\rangle_{\mathsf{s}}$$

Finally suppose that R even is a field, referring to the generated sub-ring we can also give an explicit description of the sub-field of R generated by X

$$\langle X\rangle_{\mathsf{f}} = \left\{ ab^{-1} \mid a, b \in \langle X\rangle_{\mathsf{r}},\ b \neq 0 \right\}$$

Ideals have been introduced into the thoery of rings, as computations with ordinary elements of rings may have very strange results. Thus instead of looking at $a \in R$ one may turn to $aR \trianglelefteq_{\mathsf{i}} R$ (in a commutative ring). It turns out that it is possible to define the sum and product of ideals, as well and that this even has nicer properties than the ordinary sum and product of elements. Hence the name - aR is an *ideal* element of R. Nowadays ideals have become an indispensable tool in ring theory, mainly because they will turn out to be kernels of ring-homomorphisms. Let us turn our attention to computations with ideals:

(1.56) Proposition: (viz. 731)
Consider any semi-ring $(R,+,\cdot)$ and arbitrary ideals $\mathfrak{a}$, $\mathfrak{b}$ and $\mathfrak{c} \trianglelefteq_{\mathrm{i}} R$. Then we can use these to introduce the following subsets of R, which will always be ideals of R again

$$\begin{aligned} \mathfrak{a} \cap \mathfrak{b} &= \{\, a \in R \mid a \in \mathfrak{a} \text{ and } a \in \mathfrak{b} \,\} \\ \mathfrak{a} + \mathfrak{b} &:= \{\, a + b \mid a \in \mathfrak{a}, b \in \mathfrak{b} \,\} \\ \mathfrak{a}\,\mathfrak{b} &:= \left\{ \sum_{i=1}^{n} a_i b_i \;\middle|\; 1 \leq n \in \mathbb{N},\, a_i \in \mathfrak{a},\, b_i \in \mathfrak{b} \right\} \end{aligned}$$

Note however that $\mathfrak{a} \cup \mathfrak{b}$ need *not* be an ideal of R (it will generate the ideal $\mathfrak{a} + \mathfrak{b}$, see below). And thereby we have the following chain of inclusions of subsets of R

$$\mathfrak{a}\,\mathfrak{b} \;\subseteq\; \mathfrak{a} \cap \mathfrak{b} \;\subseteq\; \mathfrak{a} \cup \mathfrak{b} \;\subseteq\; \mathfrak{a} + \mathfrak{b}$$

(1.57) Proposition: (viz. 731)
Let $(R,+,\cdot)$ be any semi-ring, then the compositions $\cap$, $+$ and $\cdot$ of ideals are associative, that is if $\mathfrak{a}$, $\mathfrak{b}$ and $\mathfrak{c} \trianglelefteq_{\mathrm{i}} R$ are ideals of R, then we get

$$\begin{aligned} (\mathfrak{a} \cap \mathfrak{b}) \cap \mathfrak{c} &= \mathfrak{a} \cap (\mathfrak{b} \cap \mathfrak{c}) \\ (\mathfrak{a} + \mathfrak{b}) + \mathfrak{c} &= \mathfrak{a} + (\mathfrak{b} + \mathfrak{c}) \\ (\mathfrak{a}\,\mathfrak{b})\,\mathfrak{c} &= \mathfrak{a}\,(\mathfrak{b}\,\mathfrak{c}) \end{aligned}$$

Further $\cap$ and $+$ are commutative, and if R is commutative then so is the multiplication $\cdot$ of ideals, formally again (with $\mathfrak{a}$ and $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ again) we get the identities of

$$\begin{aligned} \mathfrak{a} \cap \mathfrak{b} &= \mathfrak{b} \cap \mathfrak{a} \\ \mathfrak{a} + \mathfrak{b} &= \mathfrak{b} + \mathfrak{a} \\ \mathfrak{a}\,\mathfrak{b} &= \mathfrak{b}\,\mathfrak{a} \end{aligned}$$

Recall that the last equality need not hold true, unless R is commutative! Addition $+$ and multiplication $\cdot$ of ideals even satisfy the distributivity laws, that is for any ideals $\mathfrak{a}$, $\mathfrak{b}$ and $\mathfrak{c} \trianglelefteq_{\mathrm{i}} R$ we also get

$$\begin{aligned} \mathfrak{a}\,(\mathfrak{b} + \mathfrak{c}) &= (\mathfrak{a}\,\mathfrak{b}) + (\mathfrak{a}\,\mathfrak{c}) \\ (\mathfrak{a} + \mathfrak{b})\,\mathfrak{c} &= (\mathfrak{a}\,\mathfrak{c}) + (\mathfrak{b}\,\mathfrak{c}) \end{aligned}$$

(1.58) Remark:
It is clear that for any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ we get $\mathfrak{a} \cap R = \mathfrak{a}$. Thus $(\mathrm{Ideal}(R), \cap)$ is a commutative monoid with neutral element R. Likewise we get $\mathfrak{a} + 0 = \mathfrak{a}$ for any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ and hence $(\mathrm{Ideal}(R), +)$ is a commutative monoid with neutral element 0. Finally $\mathfrak{a}\,R = \mathfrak{a} = R\,\mathfrak{a}$ for any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ and hence $(\mathrm{Ideal}(R), \cdot)$ is a monoid with neutral element R, as well. And if R is commutative, so is $(\mathrm{Ideal}(R), \cdot)$. In this sense it is understood that $\mathfrak{a}^0 := R$ and $\mathfrak{a}^i := \mathfrak{a} \ldots \mathfrak{a}$ (i-times) for $1 \leq i \in \mathbb{N}$.

(1.59) Proposition: (viz. 731)
Now consider a ring $(R,+,\cdot)$ and two arbitrary subsets X and $Y \subseteq R$. Let $\mathfrak{a} = \langle X \rangle_{\mathfrak{i}}$ and $\mathfrak{b} = \langle Y \rangle_{\mathfrak{i}}$ be the ideals generated by these. Then the sum $\mathfrak{a}+\mathfrak{b}$ is generated by the union $X \cup Y$, formally that is

$$\mathfrak{a}+\mathfrak{b} \;=\; \langle X \cup Y \rangle_{\mathfrak{i}}$$

And if R is commutative, then the product $\mathfrak{a}\,\mathfrak{b}$ is generated by the point-wise product XY of these sets, that is $XY := \{\, xy \mid x \in X, y \in Y \,\}$ and thereby we get

$$\mathfrak{a}\,\mathfrak{b} \;=\; \langle XY \rangle_{\mathfrak{i}}$$

(1.60) Remark: (viz. 732)

(i) Due to (1.59) it often makes sense to regard sums $\mathfrak{a}+\mathfrak{b}$ or products $\mathfrak{a}\,\mathfrak{b}$ of ideals. And in (1.66) we will also the notion $\mathfrak{b}/\mathfrak{a}$ of a quotient of ideals. Thus one might also be led to think that there should be something like a *difference* of ideals. A good candidate would be the following: Consider the ideals $\mathfrak{a} \subseteq \mathfrak{b} \trianglelefteq_{\mathfrak{i}} R$ in some semi-ring $(R,+,\cdot)$. Then we might take $\langle \mathfrak{b} \setminus \mathfrak{a} \rangle_{\mathfrak{i}}$ to be the difference of $\mathfrak{b}$ minus $\mathfrak{a}$. Yet this yields nothing new, since

$$\mathfrak{a} \subset \mathfrak{b} \quimplies \mathfrak{b} = \langle \mathfrak{b} \setminus \mathfrak{a} \rangle_{\mathfrak{i}}$$

(ii) Let $(R,+,\cdot)$ be a ring again and $\mathfrak{a}_1, \ldots, \mathfrak{a}_n \trianglelefteq_{\mathfrak{i}} R$ be a finite family of ideals of R. Then using (1.59) and induction on n it is clear that

$$\sum_{i=1}^{n} \mathfrak{a}_i \;:=\; \left\{ \sum_{i=1}^{n} a_i \;\middle|\; a_i \in \mathfrak{a}_i \right\} \;=\; \langle \bigcup_{i=1}^{n} \mathfrak{a}_i \rangle_{\mathfrak{i}}$$

This property inspires us to define the sum of an arbitrary family ($i \in I$) of ideals $\mathfrak{a}_i \trianglelefteq_{\mathfrak{i}} R$ of R. As it is not clear what we should substitute for the finite sum of elements we instead define

$$\sum_{i \in I} \mathfrak{a}_i \;:=\; \langle \bigcup_{i \in I} \mathfrak{a}_i \rangle_{\mathfrak{i}}$$

(iii) And thereby it turns out that the *infinite* sum consists of arbitrarily large but finite sums over elements of the $\mathfrak{a}_i$, formally that is

$$\begin{aligned}
\sum_{i \in I} \mathfrak{a}_i \;&=\; \left\{ \sum_{i \in I} a_i \;\middle|\; a_i \in \mathfrak{a}_i,\ \#\{\, i \in I \mid a_i \neq 0 \,\} < \infty \right\} \\
&=\; \left\{ \sum_{i \in \Omega} a_i \;\middle|\; a_i \in \mathfrak{a}_i,\ \Omega \subseteq I,\ \#\Omega < \infty \right\} \\
&=\; \left\{ \sum_{k=1}^{n} a_k \;\middle|\; n \in \mathbb{N},\ i(k) \in I,\ a_k \in \mathfrak{a}_{i(k)} \right\}
\end{aligned}$$

(iv) Let now $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ be another ideal of R, then the distributivity rule of (1.57) generalizes to the case of infinite sums, that is

$$\left(\sum_{i\in I}\mathfrak{a}_i\right)\mathfrak{b} \;=\; \sum_{i\in I}(\mathfrak{a}_i\mathfrak{b})$$

(1.61) Proposition: (viz. 733)
Let $(R,+,\cdot)$ be a commutative ring and consider the ideals $\mathfrak{a}$, $\mathfrak{b}$, $\mathfrak{a}_1,\ldots,\mathfrak{a}_k$ and $\mathfrak{b}_1,\ldots,\mathfrak{b}_k \trianglelefteq_{\mathrm{i}} R$ of R (for some $1 \leq k \in \mathbb{N}$). Then we obtain the statements

(i) $\mathfrak{a}$ and $\mathfrak{b}$ are said to be **coprime** iff they satisfy one of the following three equivalent conditions

(a) $\mathfrak{a}+\mathfrak{b} \;=\; R$

(b) $(1+\mathfrak{a})\cap\mathfrak{b} \neq \emptyset$

(c) $\exists\, a\in\mathfrak{a},\ \exists\, b\in\mathfrak{b}$ such that $a+b=1$

(ii) Suppose that $\mathfrak{a}$ and $\mathfrak{b}$ are coprime and consider any $i, j \in \mathbb{N}$, then the powers $\mathfrak{a}^i$ and $\mathfrak{b}^j$ are coprime as well, formally that is the implication

$$\mathfrak{a}+\mathfrak{b}=R \quad\Longrightarrow\quad \mathfrak{a}^i+\mathfrak{b}^j=R$$

(iii) Suppose that for any $i \in 1\ldots k$ the ideals $\mathfrak{a}$ and $\mathfrak{b}_i$ are coprime, then the ideals $\mathfrak{a}$ and $\mathfrak{b}_1\ldots\mathfrak{b}_k$ are coprime as well, formally again this is

$$\Big(\forall\, i\in 1\ldots k : \mathfrak{a}+\mathfrak{b}_i=R\Big) \quad\Longrightarrow\quad \mathfrak{a}+(\mathfrak{b}_1\ldots\mathfrak{b}_k)=R$$

(iv) Suppose that the $\mathfrak{a}_1$ to $\mathfrak{a}_k$ are *pairwise* coprime, then the product of these ideals equals their intersection. Formally this is to say, that we have the implication

$$\Big(\forall\, i\neq j\in 1\ldots k : \mathfrak{a}_i+\mathfrak{a}_j \;=\; R\Big) \quad\Longrightarrow\quad \mathfrak{a}_1\cap\cdots\cap\mathfrak{a}_k \;=\; \mathfrak{a}_1\ldots\mathfrak{a}_k$$

(1.62) Definition: (viz. 734)
Let $(R,+,\cdot)$ be any semi-ring and $\mathfrak{a} \leq_{\mathrm{m}} R$ be a left-ideal of R, then $\mathfrak{a}$ induces an equivalence relation $\sim$ on R by virtue of: For any $a, b \in R$ we define $a \sim b$ by

$$a\sim b \quad:\Longleftrightarrow\quad a-b\in\mathfrak{a}$$

The equivalence classes under this relation are called **cosets** of $\mathfrak{a}$, and for any $b \in R$ this is given to be

$$b+\mathfrak{a} \;:=\; [b] \;=\; \{\, b+a \mid a\in\mathfrak{a}\,\}$$

(refer to (0.13) for more details on this). Finally we denote the **quotient set** R modulo $\mathfrak{a}$ to be the quotient set of R under this equivalence relation $\sim$. We denote it by

$$R\Big/_{\mathfrak{a}} \;:=\; R\Big/_{\sim} \;=\; \{\, a+\mathfrak{a} \mid a\in R\,\}$$

If $\mathfrak{a} \trianglelefteq_i R$ even is an ideal (e.g. when R is commutative) then $R/\mathfrak{a}$ can even be turned into a semi-ring $(R/\mathfrak{a}, +, \cdot)$ again under the following operations

$$\begin{aligned}(a+\mathfrak{a})+(b+\mathfrak{a}) &:= (a+b)+\mathfrak{a}\\ (a+\mathfrak{a})\cdot(b+\mathfrak{a}) &:= (a\cdot b)+\mathfrak{a}\end{aligned}$$

Thereby $(R/\mathfrak{a}, +, \cdot)$ is also called the **quotient ring** or **residue ring** of R modulo $\mathfrak{a}$. Clearly, if R is commutative, then so is $R/\mathfrak{a}$. And if R is a ring, so is $R/\mathfrak{a}$, where the unit element is given to be the coset $1+\mathfrak{a}$.

(1.63) Remark:
It is common that beginners in the field of algebra encounter problems with this notion. But on the other hand the construction of taking to the quotient ring is one of the three most important tools of algebra (the others being localizing and taking tensor products). Hence we would like to append a few remarks: We have defined $R/\mathfrak{a}$ to be the quotient set of R under the equivalence relation $a-b \in \mathfrak{a}$. And the equivalence classes have been the cosets $b+\mathfrak{a}$. Hence two cosets are equal if and only if their representatives are equivalent and formally for any $a, b \in R$ this is

$$a+\mathfrak{a} = b+\mathfrak{a} \iff a-b \in \mathfrak{a}$$

And if $\mathfrak{a} \trianglelefteq_i R$ is an ideal of R we even were able to turn this quotient set $R/\mathfrak{a}$ into a ring again, under the operations above. Now don't be confused, we sometimes also employ the point-wise sum $A+B := \{\, a+b \mid a \in A, b \in B \,\}$ and product $A \cdot B := \{\, ab \mid a \in A, b \in B \,\}$ of two subsets $A, B \subseteq R$. But this a completely different story - the operations on cosets $b+\mathfrak{a}$ have been *defined* by referring to the representatives b.

(1.64) Example: (viz. 734)
Let $1 \leq n \in \mathbb{N}$ be a positive integer and consider the ideal $n\mathbb{Z} \trianglelefteq_i \mathbb{Z}$. Then we wish to present an example of the above remark: If a and $b \in \mathbb{Z}$ are any two integers, then the following three statements are equivalent

(a) $a+n\mathbb{Z} = b+n\mathbb{Z}$

(b) $a \mod n = b \mod n$

(c) there is some $k \in \mathbb{Z}$ such that $b = a+kn$

(1.65) Remark:
Intuitively speaking the residue ring $R/\mathfrak{a}$ is the ring R where all the information contained in $\mathfrak{a}$ has been erased. Thus $R/\mathfrak{a}$ only retains the information that has been stored in R but not in $\mathfrak{a}$. Hence it is no wonder that $R/\mathfrak{a}$ is "smaller" than R ($|R/\mathfrak{a}| \leq |R|$ to be precise). However $R/\mathfrak{a}$ is *not* a sub-ring of R! Let us study some special cases to enlighten things:

- In the case $\mathfrak{a} = R$ the residue ring R/R contains precisely one element, namely $0+R$. Hence $R/R = \{\, 0+R \,\}$ is the zero-ring. This matches the intuition all information has been forgotten, what remains carries the trivial structure only.

- The other extreme case is $\mathfrak{a} = \{0\}$. In this case $\mathfrak{a}$ induces the trivial relation $a \sim b \iff a = b$. Hence the residue class of a is just $a + \{0\} = \{a\}$. Therefore we have a natural identification

$$R \longleftrightarrow R \Big/ _{\{0\}} \; : \; a \mapsto \{ a \}$$

 Again this matches the intuition: $\{0\}$ contains no information hence $R/\{0\}$ retains all the information of R. In fact we have just rewritten any $a \in R$ as $\{a\} \in R/\{0\}$.

- Now consider any commutative ring $(R, +, \cdot)$ and build the polynomial ring $R[t]$ upon it. Then the ideal $\mathfrak{a} = tR[t]$ allows us to regain R from $R[t]$. Formally there is a natural identification

$$R \longleftrightarrow R[t] \Big/ _{tR[t]} \; : \; a \mapsto at^0 + tR[t]$$

 Hence one should think that $tR[t]$ contains the information we have added by going to the polynomial ring $R[t]$. Forgetting it we return to R. Further it is nice to note that the same is true for the formal power series $R[\![t]\!]$ instead of $R[t]$. The same amount of information that has been added is lost, by taking to the quotient ring.

 Prob it is clear that $R \to R[t] : a \mapsto at^0$ is injective and for $a \neq b \in R$ we even get $at^0 - bt^0 = (a-b)t^0 \notin tR[t]$. This means that even $a \mapsto at^0 + tR[t]$ is injective. And if we are given an arbitrary polynomial $f = a_n t^n + \cdots + a_1 t + a_0 t^0$ then $f + tR[t] = a_0 t^0 + tR[t]$ which also is the surjectivity. Note that this all is immediate from the first isomorphism theorem: $R[t] \to R : f \mapsto f[0]$ has kernel $tR[t]$ and image R.

- Likewise (for any $1 \leq n \in \mathbb{N}$) we obtain a natural identification between the ring $\mathbb{Z}_n$ (as defined in (1.28)) and the residue ring $\mathbb{Z}/n\mathbb{Z}$ via the isomorphism

$$\mathbb{Z} \Big/ _{n\mathbb{Z}} \; \xrightarrow{\sim} \; : \; a + n\mathbb{Z} \; \mapsto \; a \mod n$$

 This example teaches that the properties of the residue ring (here $\mathbb{Z}/n\mathbb{Z}$) may well differ from those of the ring (here $\mathbb{Z}$). E.g. $\mathbb{Z}$ is an integral domain, whereas $\mathbb{Z}/4\mathbb{Z}$ is not $((2 + 4\mathbb{Z})(2 + 4\mathbb{Z}) = 0 + 4\mathbb{Z})$. On the other hand $\mathbb{Z}/2\mathbb{Z}$ is a field, whereas $\mathbb{Z}$ is not.

 Prob first of all $\Phi(a + n\mathbb{Z}) = a \mod n$ is well-defined and bijective, according to (1.64). The inverse map is just the canonical projection $\varrho(r) = r + n\mathbb{Z}$. For the homomorphism property of Φ let us write (by division with remainder) $a = pn + r$ and $b = qn + s$ where $r = a \mod n$ and $s = b \mod n$. Then $a + b = (p + q)n + (r + s)$ and $ab = (pqn + ps + qr)n + rs$. Hence we can compute, using (1.64) again

$$\begin{aligned} \Phi((a + n\mathbb{Z}) + (b + n\mathbb{Z})) &= (a + b) \mod n = (r + s) \mod n \\ \Phi((a + n\mathbb{Z}) \cdot (b + n\mathbb{Z})) &= (ab) \mod n = (rs) \mod n \end{aligned}$$

 But by definition of $\mathbb{Z}_n$ we have the compositions $r + s = (r + s) \mod n$ and $rs = (rs) \mod n$ hence Φ truly transfers the structure of $\mathbb{Z}/n\mathbb{Z}$ onto $\mathbb{Z}_n$. In particular $\mathbb{Z}_n$ is a commutative ring again.

(1.66) Lemma: (viz. 734)

Correspondence Theorem: Consider any semi-ring $(R,+,\cdot)$ and an ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$, then we obtain a 1-to-1 correspondence between the ideals of the residue ring $R/\mathfrak{a}$ and the ideals of R containing $\mathfrak{a}$. For this correspondence let us denote $\mathfrak{b}/\mathfrak{a} := \{ b+\mathfrak{a} \mid b \in \mathfrak{b} \}$, then we get

$$\begin{array}{rcl} \text{Ideal}\left(R\big/\mathfrak{a}\right) & \longleftrightarrow & \{ \mathfrak{b} \trianglelefteq_{\mathfrak{i}} R \mid \mathfrak{a} \subseteq \mathfrak{b} \} \\ \mathfrak{u} & \mapsto & \{ b \in R \mid b+\mathfrak{a} \in \mathfrak{u} \} \\ \mathfrak{b}\big/\mathfrak{a} & \hookleftarrow & \mathfrak{b} \end{array}$$

And this correspondence even is compatible with intersections, sums and products of deals and the generation of ideals. To be precise, we get the following three additional statements

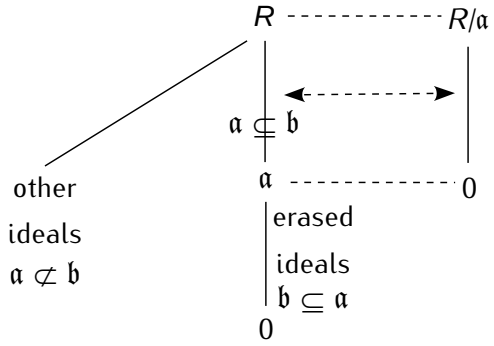
(i) Consider an arbitrary subset $X \subseteq R$ and denote $X/\mathfrak{a} := \{ x+\mathfrak{a} \mid x \in X \}$ its set of residue classes. Then the ideal generated by $X/\mathfrak{a}$ is the ideal generated by $X \cup \mathfrak{a}$ modulo $\mathfrak{a}$

$$\langle X \rangle_{\mathfrak{i}} + \mathfrak{a}\big/\mathfrak{a} \;=\; \langle X\big/\mathfrak{a} \rangle_{\mathfrak{i}}$$

(ii) Let $I \neq \emptyset$ be any non-empty index set and for any $i \in I$ let $\mathfrak{b}_i \trianglelefteq_{\mathfrak{i}} R$ be an ideal of R containing $\mathfrak{a} \subseteq \mathfrak{b}_i$. Then we get the following identities for the sums and intersections

$$\begin{aligned} \bigcap_{i\in I} \mathfrak{b}_i\big/\mathfrak{a} &= \textstyle\bigcap_{i\in I} \mathfrak{b}_i\big/\mathfrak{a} \\ \sum_{i\in I} \mathfrak{b}_i\big/\mathfrak{a} &= \textstyle\sum_{i\in I} \mathfrak{b}_i\big/\mathfrak{a} \end{aligned}$$

(iii) If $\mathfrak{b}_1, \ldots, \mathfrak{b}_n \trianglelefteq_{\mathfrak{i}} R$ are finitely many ideals of R containing $\mathfrak{a} \subseteq \mathfrak{b}_i$ (for any $i \in 1 \ldots n$), then we get the following identity for the products



$$\prod_{i=1}^{n} \mathfrak{b}_i\big/\mathfrak{a} \;=\; \textstyle\prod_{i=1}^{n} \mathfrak{b}_i\big/\mathfrak{a}$$

(1.67) Remark:
Let $(R,+,\cdot)$ be a semi-ring and $\mathfrak{a}, \mathfrak{b} \trianglelefteq_{\mathfrak{i}} R$ be two ideals, such that $\mathfrak{a} \subseteq \mathfrak{b}$. Recall that we defined the ideal $\mathfrak{b}/\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R/\mathfrak{a}$ to be the set $\mathfrak{b}/\mathfrak{a} = \{ b+\mathfrak{a} \mid b \in \mathfrak{b} \}$. Then it is easy to see that for any $x \in R$ we even get the following equivalence

$$x \in \mathfrak{b} \iff x+\mathfrak{a} \in \mathfrak{b}\big/\mathfrak{a}$$

Prob If $x \in \mathfrak{b}$ then $x+\mathfrak{a} \in \mathfrak{b}/\mathfrak{a}$ is true by definition. And if conversely $x+\mathfrak{a} \in \mathfrak{b}/\mathfrak{a}$ then there is some $b \in \mathfrak{b}$ such that $x+\mathfrak{a} = b+\mathfrak{a}$. That is $x-b \in \mathfrak{a} \subseteq \mathfrak{b}$ and hence $x+\mathfrak{b} = b+\mathfrak{b} = 0+\mathfrak{b}$ again. But the latter already means $x \in \mathfrak{b}$.

(1.68) Remark:
The following graphic is supposed to illustrate the situation: Going from R to $R/\mathfrak{a}$ all the ideals below $\mathfrak{a}$ are deleted, while those ideals $\mathfrak{b} \trianglelefteq_{\mathfrak{i}} R$ with $\mathfrak{a} \subseteq \mathfrak{b}$ are preserved. Those ideals that were not comparable to $\mathfrak{a}$ are lost entirely, their algebraic structure defaced:

(1.69) Remark:
We will soon introduce the notion of a homomorphism, an example of such a thing is the following map that sends $b \in R$ to its equivalence class $b + \mathfrak{a}$ of $R/\mathfrak{b}$

$$\varrho \;:\; R \twoheadrightarrow R\Big/_{\mathfrak{a}} \;:\; b \mapsto b + \mathfrak{a}$$

It is clear that this mapping is surjective. And by definition the preimage of any subset $\mathfrak{u} \subseteq R/\mathfrak{a}$ is just $\varrho^{-1}(\mathfrak{u}) = \{\, b \in R \mid b + \mathfrak{a} \in \mathfrak{u} \,\}$. Finally it also is clear that for any ideal $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ with $\mathfrak{a} \subseteq \mathfrak{b}$ the image of $\mathfrak{b}$ under ϱ is given to be

$$\varrho(\mathfrak{b}) \;=\; \{\, b + \mathfrak{a} \mid b \in \mathfrak{b} \,\} \;=\; \mathfrak{b}\Big/_{\mathfrak{a}}$$

Altogether that is: The above correspondence of ideals is just given by ϱ acting on certain subsets of R (to be precise: on the set of ideals $\mathfrak{b}$ of R that contain $\mathfrak{a}$). That is using these concepts, we could have written the correspondence theorem of ideals in terms of $\mathfrak{b} \mapsto \varrho(\mathfrak{b})$ and $\mathfrak{u} \mapsto \varrho^{-1}(\mathfrak{u})$.

(1.70) Example:
Let us give a well-known, neat little application of the theory: The usual way of denoting integers $a \in \mathbb{Z}$ is using the *decimal representation*, e.g. $273 = 2 \cdot 100 + 7 \cdot 10 + 3 \cdot 1$. Generally we write $a = a_n \ldots a_1 a_0$ iff $a_k \in 0 \ldots 9$ and

$$a \;=\; \sum_{k=0}^{n} a_k \cdot 10^k$$

As 2 divides 10 we get $a + 2\mathbb{Z} = a_0 + 2\mathbb{Z}$ and hence it is clear that 2 divides a if and only if 2 divides a_0 (the same holds true if we replace 2 by 5). We will introduce the notation $a \mid b$ for *a divides b* in (2.48). Using this already, we have just seen the equivalence, of

$$2 \mid a \quad\Longleftrightarrow\quad 2 \mid a_0$$

Also it is customary to define the *cross-sum* of a to be the sum of the digits a_k in the decimal representation of a. That is for the above a we define the map $\varphi : \mathbb{Z} \to \mathbb{Z}$ by letting

$$\phi(a) \;:=\; \sum_{k=0}^{n} a_k \;\in\; \mathbb{N}$$

E.g. the cross sum of 273 is $2+7+3=12$. Now, as $10=3\cdot 3+1$ we have $10+3\mathbb{Z}=1+3\mathbb{Z}$, and thereby $10^k+3\mathbb{Z}=(10+3\mathbb{Z})^k=(1+3\mathbb{Z})^k=1+3\mathbb{Z}$. This enables us to compute

$$\begin{aligned} a+3\mathbb{Z} &= \sum_{k=0}^{n} a_k\cdot 10^k+3\mathbb{Z} = \sum_{k=0}^{n} a_k\cdot(10^k+3\mathbb{Z}) \\ &= \sum_{k=0}^{n} a_k\cdot(1+3\mathbb{Z}) = \sum_{k=0}^{n} a_k+3\mathbb{Z} = \phi(a)+3\mathbb{Z} \end{aligned}$$

That is $a+3\mathbb{Z}=\phi(a)+3\mathbb{Z}$ and in particular we have $3 \mid a$ if and only if $\phi(a)+3\mathbb{Z}=a+3\mathbb{Z}=0+3\mathbb{Z}$ which is equivalent to $3 \mid \phi(a)$ again. That is we can check whether a is divisible by 3 just by checking whether the cross-sum $\phi(a)$ of a is divisible by 3.

$$3 \mid a \iff 3 \mid \phi(a)$$

E.g. $\phi(273)=12$ is divisible by 3 and hence 273 is divisible by 3, as well - in fact $273=3\cdot 91$. We can even iterate the cross summation, e.g. $\phi(\phi(273))=3$ which is easier to divide by 3. Also, as $10+9\mathbb{Z}=1+9\mathbb{Z}$ as well, the same reasoning holds true if we replace 3 by 9.

(1.71) Remark: $(\diamondsuit)$
Actually we have already shown some further statements in the proof of (1.66) concerning notions, that have to be introduced, yet: Let $(R,+,\cdot)$ be a commutative ring, then the above correspondence of ideals also interlocks maximal ideals, prime ideals and radical ideals, that is:

$$\begin{array}{ccc} \mathrm{Ideal}\left(R/\mathfrak{a}\right) & \longleftrightarrow & \{\,\mathfrak{b}\in \mathrm{Ideal}R \mid \mathfrak{a}\subseteq\mathfrak{b}\,\} \\ \cup & & \cup \\ \mathrm{Srad}\left(R/\mathfrak{a}\right) & \longleftrightarrow & \{\,\mathfrak{b}\in \mathrm{Srad}(R) \mid \mathfrak{a}\subseteq\mathfrak{b}\,\} \\ \cup & & \cup \\ \mathrm{Spec}\left(R/\mathfrak{a}\right) & \longleftrightarrow & \{\,\mathfrak{p}\in \mathrm{Spec}(R) \mid \mathfrak{a}\subseteq\mathfrak{p}\,\} \\ \cup & & \cup \\ \mathrm{Smax}\left(R/\mathfrak{a}\right) & \longleftrightarrow & \{\,\mathfrak{m}\in \mathrm{Smax}(R) \mid \mathfrak{a}\subseteq\mathfrak{m}\,\} \end{array}$$

That is the ideal $\mathfrak{b}\trianglelefteq_{\mathrm{i}} R$ with $\mathfrak{a}\subseteq\mathfrak{b}$ is radical if and only if the corresponding ideal $\mathfrak{b}/\mathfrak{a}\trianglelefteq_{\mathrm{i}} R/\mathfrak{a}$ is radical, too. Likewise $\mathfrak{a}\subseteq\mathfrak{b}\trianglelefteq_{\mathrm{i}} R$ is prime (maximal) iff $\mathfrak{b}/\mathfrak{a}\trianglelefteq_{\mathrm{i}} R/\mathfrak{a}$ is prime (maximal). In fact we even have the following equality of radical ideals for any $\mathfrak{b}\trianglelefteq_{\mathrm{i}} R$ with $\mathfrak{a}\subseteq\mathfrak{b}$

$$\sqrt{\mathfrak{b}/\mathfrak{a}} = \sqrt{\mathfrak{b}}/\mathfrak{a}$$

(1.72) Example: $(\diamondsuit)$
Consider the ring $(\mathbb{Z},+,\cdot)$, as $\mathbb{Z}$ is an Euclidean domain all its ideals are of the form $a\mathbb{Z}$ for some $a\in\mathbb{Z}$ (cf. to section 2.7 for a proof). We now fix some ideal $\mathfrak{a}:=a\mathbb{Z}$, then $a\mathbb{Z}\subseteq b\mathbb{Z}$ is equivalent to b dividing a (see section 2.5 for details). Hence by the correspondence theorem the ideals of $\mathbb{Z}_a=\mathbb{Z}/a\mathbb{Z}$ are

$$\mathrm{Ideal}\left(\mathbb{Z}/a\mathbb{Z}\right) = \left\{ b\mathbb{Z}/a\mathbb{Z} \;\middle|\; b \mid a \right\}$$

1.7 Homomorphisms

(1.73) Definition:
Let $(R,+,\cdot)$ and $(S,+,\cdot)$ be arbitrary semi-rings, a mapping $\varphi : R \to S$ is said to be a **homomorphism of semi-rings** (or shortly a *semi-ring-homomorphism*) iff for any $a, b \in R$ it satisfies the properties

(1) $\varphi(a+b) \;=\; \varphi(a)+\varphi(b)$

(2) $\varphi(a\cdot b) \;=\; \varphi(a)\cdot\varphi(b)$

And if R and S even are rings having the unit elements 1_R and 1_S respectively, then φ is said to be a **homomorphism of rings** (or shortly a *ring-homomorphism*) iff for any $a, b \in R$ it satisfies the properties

(1) $\varphi(a+b) \;=\; \varphi(a)+\varphi(b)$

(2) $\varphi(a\cdot b) \;=\; \varphi(a)\cdot\varphi(b)$

(3) $\varphi(1_R) \;=\; 1_S$

And we will denote the set of all semi-ring-homomorphisms, respectively of all ring-homomorphisms (as such, these are subsets of $\mathcal{F}(R,S)$), from R to S by

$$\begin{aligned} \mathrm{shom}(R,S) &:= \{\, \varphi : R \to S \mid (1) \text{ and } (2) \,\} \\ \mathrm{rhom}(R,S) &:= \{\, \varphi : R \to S \mid (1), (2) \text{ and } (3) \,\} \end{aligned}$$

And if $\varphi : R \to S$ is a homomorphism of semi-rings, then we define its **image** $\mathrm{im}(\varphi) \subseteq S$ and its **kernel** $\mathrm{kn}(\varphi) \subseteq R$ to be the following subsets, of the respective semi-rings

$$\begin{aligned} \mathrm{im}(\varphi) &:= \varphi(R) \;=\; \{\, \varphi(a) \mid a \in R \,\} \\ \mathrm{kn}(\varphi) &:= \varphi^{-1}(0_S) \;=\; \{\, a \in R \mid \varphi(a) = 0 \,\} \end{aligned}$$

(1.74) Remark:
In literature it is customary to only write $\mathrm{hom}(R,S)$ instead of what we denoted by $\mathrm{shom}(R,S)$ or $\mathrm{rhom}(R,S)$. And precisely which of these two sets is meant is determined by context only, not by notation. This ambiguity gets worse with every new algebraic structure introduced and there will be quite a lot. In this text we try to increase clarity by adding the letters "s" or "r". From a systematic point of view it might be appealing to write $\mathrm{hom}_s(R,S)$ for $\mathrm{shom}(R,S)$ (and likewise $\mathrm{hom}_r(R,S)$ for $\mathrm{rhom}(R,S)$), as we have already used these indexes with substructures. Yet we will require the position of the index later on (when it comes to modules and algebras). Hence we chose to place precisely this index in front of "hom" instead.

(1.75) Example:

- The easiest example of a homomorphism of semi-rings is the so-called *zero-homomorphism* which we denote by 0 (clearly another ambiguity) and which is given to be

$$0 \;:\; R \to S \;:\; a \mapsto 0_S$$

- Let $(S,+,\cdot)$ be any semi-ring and $R \leq_s S$ be a sub-semi-ring of S. Then the inclusion $R \subseteq S$ gives rise the the *inclusion homomorphism*

$$\iota \,:\, R \hookrightarrow S \,:\, a \mapsto a$$

 Clearly this is a homomorphism of semi-rings. And if S even is a ring and $R \leq_r S$ is a sub-ring of S, then ι is a homomorphism of rings. in the special case $R = S$ this is $\iota = \mathbb{1}_R$ the *identity map*.

- Now let $(R,+,\cdot)$ be any (semi-)ring and consider some ideal $\mathfrak{a} \trianglelefteq_i R$. Then we already have introduced the quotient (semi-)ring $R/\mathfrak{a}$ in (1.62). And this gives rise to the following homomorphism of (semi-) rings (which is called *canonical epimorphism*)

$$\varrho \,:\, R \twoheadrightarrow R\Big/_{\mathfrak{a}} \,:\, b \mapsto b + \mathfrak{a}$$

 Note that the definition of the addition and multiplication on $R/\mathfrak{a}$ are precisely the properties of ϱ being a homomorphism. And also by definition the kernel of this map precisely is $\ker(\varrho) = \mathfrak{a}$. Of course ϱ is surjective and hence its image is the entire ring $\operatorname{im}(\varrho) = R/\mathfrak{a}$.

- Consider any (semi-)ring $(R,+,\cdot)$ again and let $\mathfrak{a}$, $\mathfrak{b} \trianglelefteq_i R$ be two ideals of R such that $\mathfrak{a} \subseteq \mathfrak{b}$. Then we obtain a well-defined, surjective homomorphism of (semi-)rings by letting (further note that the kernel of this map is given to be the quotient ideal $\mathfrak{b}/\mathfrak{a}$)

$$R\Big/_{\mathfrak{a}} \twoheadrightarrow R\Big/_{\mathfrak{b}} \,:\, a + \mathfrak{a} \mapsto a + \mathfrak{b}$$

 Prob if $a + \mathfrak{a} = b + \mathfrak{a}$ then $a - b \in \mathfrak{a} \subseteq \mathfrak{b}$ whence we get $a + \mathfrak{b} = b + \mathfrak{b}$ again. This already is the well-definedness and the surjectivity and homomorphism properties are clear. Further $b + \mathfrak{b} = 0 + \mathfrak{b}$ iff $b \in \mathfrak{b}$ which again is equivalent, to $b + \mathfrak{a} \in \mathfrak{b}/\mathfrak{a}$, such that we also find $\ker(\bullet) = \mathfrak{b}/\mathfrak{a}$.

- Finally we would like to present an example of a homomorphism π of semi-rings, that is *not* a homomorphism of rings as it does not preserve the unit of R. The easiest way to achieve this is by regarding the ring $R = \mathbb{Z}^2$. Then we may take to the projection

$$\pi \,:\, \mathbb{Z}^2 \to \mathbb{Z}^2 \,:\, (a,b) \mapsto (a,0)$$

(1.76) Proposition: (viz. 736)

(i) Let $(R,+,\cdot)$ and $(S,+,\cdot)$ be semi-rings and $\varphi : R \to S$ be a homomorphism of semi-rings again. Then φ already satisfies the following properties (for any $a \in R$)

$$\begin{aligned} \varphi(0_R) &= 0_S \\ \varphi(-a) &= -\varphi(a) \end{aligned}$$

(ii) And if $(R,+,\cdot)$ and $(S,+,\cdot)$ are rings, $u \in R^*$ is an invertible element of R and $\varphi : R \to S$ is a homomorphism of rings, then $\varphi(u) \in S^*$ is an invertible element of S, too with inverse

$$\varphi(u^{-1}) = \varphi(u)^{-1}$$

(iii) Let $(R,+,\cdot)$, $(S,+,\cdot)$ and $(T,+,\cdot)$ be (semi-)rings, $\varphi : R \to S$ and $\psi : S \to T$ be homomorphisms of (semi-)rings. Then the composition ψ after φ is a homomorphism of (semi-)rings again

$$\psi\varphi \;:\; R \to S \;:\; a \mapsto \psi(\varphi(a))$$

(iv) Let $(R,+,\cdot)$ and $(S,+,\cdot)$ be (semi-)rings, $\Phi : R \to S$ be a bijective homomorphism of (semi-)rings. Then the inverse map $\Phi^{-1} : S \to R$ is a homomorphism of (semi-)rings, as well.

(v) Let $(R,+,\cdot)$ and $(S,+,\cdot)$ be (semi-)rings and $\varphi : R \to S$ be a homomorphism of (semi-)rings, then the image of φ is a sub-(semi-)ring of S and its kernel is an ideal of R

$$\begin{aligned} \mathrm{im}(\varphi) &\leq_{\mathrm{s}} S \\ \mathrm{kn}(\varphi) &\trianglelefteq_{\mathrm{i}} R \end{aligned}$$

(vi) More generally let $(R,+,\cdot)$ and $(S,+,\cdot)$ be any two (semi-)rings containing the sub-(semi-)rings $P \leq_{\mathrm{s}} R$ and $Q \leq_{\mathrm{s}} S$ respectively. If now $\varphi : R \to S$ is a homomorphism of (semi-)rings, then $\varphi(P)$ and $\varphi^{-1}(Q)$ are sub-(semi-)rings again

$$\begin{aligned} \varphi(P) &\leq_{\mathrm{s}} S \\ \varphi^{-1}(Q) &\leq_{\mathrm{s}} R \end{aligned}$$

(vii) Analogously let $(R,+,\cdot)$ and $(S,+,\cdot)$ be any two semi-rings containing the (left-)ideals $\mathfrak{a} \leq_{\mathrm{m}} R$ and $\mathfrak{b} \leq_{\mathrm{m}} S$ respectively. If now $\varphi : R \to S$ is a homomorphism of semi-rings then $\varphi^{-1}(\mathfrak{b})$ is a (left-)ideal of R again. And if φ even is surjective, then $\varphi(\mathfrak{a})$ is a (left-)ideal of R

$$\varphi^{-1}(\mathfrak{b}) \leq_{\mathrm{m}} R$$

$$\varphi \text{ surjective} \implies \varphi(\mathfrak{a}) \leq_{\mathrm{m}} R$$

(viii) Let $(R,+,\cdot)$ be a ring again and $(S,+,\cdot)$ even be a skew field. Then any non-zero homomorphism of semi-rings from R to S already is a homomorphism of rings (i.e. satisfies property (3)). Formally

$$S \text{ skew-field} \implies \mathrm{shom}(R,S) = \mathrm{rhom}(R,S) \cup \{0\}$$

(ix) Now let $(R,+,\cdot)$ be a skew-field and $(S,+,\cdot)$ be an arbitrary semi-ring, then any nonzero homomorphism $\varphi : R \to S$ of semi-rings is injective

$$R \text{ skew-field} \implies \varphi \text{ injective or } \varphi = 0$$

(1.77) Proposition: (viz. 738)
Let $(R,+,\cdot)$ be an arbitrary semi-ring and $\mathfrak{a} \trianglelefteq_i R$ be any ideal in R. Then we regard the *canonical epimorphism* from R to $R/\mathfrak{a}$, that is

$$\varrho \ : \ R \to {}^{R}\!\Big/_{\mathfrak{a}} \ : \ r \mapsto r + \mathfrak{a}$$

If now $\mathfrak{b} \trianglelefteq_i R$ is any other ideal in R then the image of $\mathfrak{b}$ under ϱ is given to be $(\mathfrak{a}+\mathfrak{b})/\mathfrak{a}$ and the preimage of this set are given to be $\mathfrak{a}+\mathfrak{b}$

$$\begin{aligned} \varrho(\mathfrak{b}) &= {}^{\mathfrak{a}+\mathfrak{b}}\!\Big/_{\mathfrak{a}} \\ \varrho^{-1}(\varrho(\mathfrak{b})) &= \mathfrak{a}+\mathfrak{b} \end{aligned}$$

(1.78) Definition:
Consider any two (semi-)rings $(R,+,\cdot)$ and $(S,+,\cdot)$ and a homomorphism $\varphi : R \to S$ of (semi-)rings. Then φ is said to be a **mono-**, **epi-** or **isomorphism** of (semi-)rings, iff it is injective, surjective or bijective respectively. And a homomorphism of the form $\varphi : R \to R$ is said to be an **endomorphism** of R. And φ is said to be an **automorphism** of R iff it is a bijective endomorphism of R. Altogether we have defined the notions

φ is called	iff φ is
monomorphism	injective
epimorphism	surjective
isomorphism	bijective
endomorphism	$R = S$
automorphism	$R = S$ and bijective

And if $(R,+,\cdot)$ is any ring, then we denote the set of all ring automorphisms on R by (note that this is a group under the composition of mappings)

$$\mathrm{raut}(R) \ := \ \{\, \Phi : R \to R \mid \Phi \text{ bijective homomorphism of rings} \,\}$$

In the case that $\Phi : R \to S$ is an isomorphism of semi-rings we will abbreviate this by writing $\Phi : R \cong_s S$. And if $\Phi : R \to S$ even is an isomorphism of rings we write $\Phi : R \cong_r S$. And thereby R and S are said to be **isomorphic** if there is an isomorphism Φ between them. And in this case we write

$$\begin{aligned} R \cong_s S \ &:\Longleftrightarrow \ \exists \Phi \ : \ \Phi : R \cong_s S \\ R \cong_r S \ &:\Longleftrightarrow \ \exists \Phi \ : \ \Phi : R \cong_r S \end{aligned}$$

(1.79) Remark:

(i) If $(R,+,\cdot)$ is any ring, the set $\mathrm{rend}(R) := \mathrm{rhom}(R,R)$ of endomorphisms of the ring R is a monoid under the composition of maps. I.e. $\mathbb{1} \in \mathrm{rend}(R)$ and if both ε and $\eta : R \to R$ are endomorphism of the ring R, then $\varepsilon\eta : R \to R : a \mapsto \varepsilon(\eta(a))$ is an endomorphism of R, as well.

(ii) If $\varepsilon \in \mathrm{rend}(R)$ is an endomorphism of R, then $\mathrm{im}(\varepsilon) = \varepsilon(R) \leq_{\mathrm{r}} R$ is a sub-ring of R. But the same is true for the *fixed ring* of ε, which is defined to be

$$\mathrm{fix}(\varepsilon) \;:=\; \{\, a \in R \mid \varepsilon(a) = a \,\} \quad \leq_{\mathrm{r}} \quad \varepsilon(R)$$

Prob As $\varepsilon(0) = 0$ and $\varepsilon(1) = 1$ by assumption we have $0, 1 \in \mathrm{fix}(\varepsilon)$. And as $\mathrm{fix}(\varepsilon) = \varepsilon(\mathrm{fix}(\varepsilon)) \subseteq \varepsilon(R) = \mathrm{im}(\varepsilon)$ is clear, this is $0, 1 \in \mathrm{im}(\varepsilon)$. Also, if $u = \varepsilon(a)$ and $v = \varepsilon(b) \in \mathrm{im}(\varepsilon)$ then $u + v = \varepsilon(a) + \varepsilon(b) = \varepsilon(a + b) \in \mathrm{im}(\varepsilon)$ and $u \cdot v = \varepsilon(a) \cdot \varepsilon(b) = \varepsilon(a \cdot b) \in \mathrm{im}(\varepsilon)$ again. Thus $\mathrm{im}(\varepsilon) \leq_{\mathrm{r}} R$ is a sub-ring of R containing $\mathrm{fix}(\varepsilon)$. Now, if $a, b \in \mathrm{fix}(\varepsilon)$ then $a + b = \varepsilon(a) + \varepsilon(b) = \varepsilon(a + b)$ and $a \cdot b = \varepsilon(a) \cot \varepsilon(b) = \varepsilon(a \cdot b)$ such that $a + b$ and $a \cdot b \in \mathrm{fix}(\varepsilon)$ again. Thus $\mathrm{fix}(\varepsilon)$ is another sub-ring of R, contained in $\mathrm{im}(\varepsilon)$.

(iii) Recall the definition of the complex numbers given in (1.35). The classical example of a ring endomorphism is the complex conjugation

$$\kappa \;:\; \mathbb{C} \to \mathbb{C} \;:\; a + ib \mapsto a - ib$$

which is an automorphism of the field $\mathbb{C}$ whose fixed ring are the reals $\mathrm{fix}(\kappa) = \mathbb{R} \subseteq \mathbb{C}$. We will later see, that κ is the only automorphism of $\mathbb{C}$ that fixes $\mathbb{R}$, apart from $\mathbb{1}$.

(iv) Another example of an endomorphism of rings $\nu : \mathbb{Z}[t] \to \mathbb{Z}[t]$ thrives on the polynomial ring $\mathbb{Z}[t]$ introduced in (1.33). We take a look at $\nu(f) := f[0]$ and see that ν neither is surjective nor injective and that the fixed ring of ν is given to be

$$\mathrm{fix}(\nu) \;=\; \mathrm{im}(\nu) \;=\; \mathbb{Z} \quad \leq_{\mathrm{r}} \quad \mathbb{Z}[t]$$

(1.80) Proposition: (viz. 738)

(i) Let $(R, +, \cdot)$ and $(S, +, \cdot)$ be semi-rings and $\varphi : R \to S$ be a homomorphism of semi-rings. Then φ is injective, iff its kernel is $0 \subseteq R$, resp. surjective iff its image is S

$$\begin{aligned} \varphi \text{ injective} &\iff \mathrm{kn}(\varphi) = \{0\} \\ \varphi \text{ surjective} &\iff \mathrm{im}(\varphi) = S \end{aligned}$$

(ii) Let $(R, +, \cdot)$ and $(S, +, \cdot)$ be (semi-)rings and $\Phi : R \to S$ be a homomorphism of (semi-)rings, then the following statements are equivalent (and in this case we already get $\alpha = \beta = \Psi = \Phi^{-1}$)

(a) Φ is bijective

(b) there is some homomorphism $\Psi : S \to R$ of (semi-)rings, such that $\Psi\Phi = \mathbb{1}_R$ and $\Phi\Psi = \mathbb{1}_S$

(c) there are arbitrary maps $\alpha : S \to R$ and $\beta : S \to R$, such that $\alpha\Phi = \mathbb{1}_R$ and $\Phi\beta = \mathbb{1}_S$

(iii) Let $(R, +, \cdot)$ and $(S, +, \cdot)$ be any two semi-rings and $\Phi : R \cong_{\mathrm{s}} S$ be an isomorphism between them. Then R is a ring if and only if S is a ring. And in this case $\Phi : R \cong_{\mathrm{r}} S$ already is an isomorphism of rings.

(iv) The relation $\cong_r$ has the properties of an equivalence relation on the class of all rings (and the same is true for $\cong_s$ on the class of all semi-rings). To be precise, for all rings $(R,+,\cdot)$, $(S,+,\cdot)$ and $(T,+,\cdot)$ we obtain the following statements

$$\mathbb{1}_R : R \cong_r R$$

$$\Phi : R \cong_r S \implies \Phi^{-1} : S \cong_r R$$

$$\Phi : R \cong_r S \text{ and } \Psi : S \cong_r T \implies \Psi\Phi : R \cong_r T$$

(1.81) Remark:
Intuitively speaking two (semi-)rings $(R,+,\cdot)$ and $(S,+,\cdot)$ are isomorphic if and only if they carry precisely the same structure. A bit lax that is the elements may differ by the names they are given but nothing more. Therefore any algebraic property satisfied by R also holds true for S and vice versa. We give a few examples of this fact below, but this is really true for *any* algebraic property. Thus from an algebraic point of view, isomorphic (semi-)rings are just two copies the same thing (just like two 1 Euro coins). And the difference between equality and isomorphy is just a set-theoretical one. We verify this intuitive view by presenting a few examples - let $(R,+,\cdot)$ and $(S,+,\cdot)$ be any two semi-rings that are isomorphic under $\Phi : R \cong_s S$. Then we get

- In the above proposition (1.80.(iii)) we have already shown R is a ring if and only if S is a ring. And in this case already Φ is an isomorphism of rings.

- R is commutative if and only if S is commutative. Prob suppose that R is commutative and consider any two elements $x, y \in S$. Then let $a := \Phi^{-1}(x)$ and $b := \Phi^{-1}(y) \in R$, then we are able to compute $xy = \Phi(a)\Phi(b) = \Phi(ab) = \Phi(ba) = \Phi(b)\Phi(a) = yx$. Hence S is commutative, too. And the converse implication follows with Φ instead of Φ^{-1}.

- R is an integral domain if and only if S is an integral domain. Prob suppose that S is an integral domain and consider any two elements $a, b \in R$. If $ab = 0$ then $0 = \Phi(0) = \Phi(ab) = \Phi(a)\Phi(b)$. But as S is an integral domain this means $\Phi(a) = 0$ or $\Phi(b) = 0$. And as Φ is injective this implies $a = 0$ or $b = 0$. Hence R is an integral domain, too. And the converse implication follows with Φ^{-1} instead of Φ.

- R is a skew-field if and only if S is a skew-field. In fact for any two rings R and S we even get the stronger correspondence

 $$\Phi(R^*) = S^*$$

 Prob if $a \in R^*$ is a unit of R then $\Phi(a^{-1}) = \Phi(a)^{-1}$ and hence $\Phi(a) \in S^*$ is a unit, too. And if conversely $x \in S^*$ is a unit of S, then let $a := \Phi^{-1}(x)$ and $b := \Phi^{-1}(x^{-1})$. Thereby $ab = \Phi^{-1}(x)\Phi^{-1}(x^{-1}) = \Phi^{-1}(xx^{-1}) = \Phi(1_S) = 1_R$ and likewise $ba = 1_R$. Hence we have $a^{-1} = b$ such that $a \in R^*$ and $x \in \Phi(R^*)$ is the image of a unit of R.

(1.82) Remark: $(\diamondsuit)$
In the chapters to come we will introduce the notion of a category (in our case this would be the collection of all semi-rings or of all rings respectively). And in any category there is the notion of *monomorphisms*, *epimorphisms* and *isomorphisms*. That is let $(R,+,\cdot)$ and $(S,+,\cdot)$ be two (semi-)rings. Then $\varphi : R \to S$ will be called a **monomorphism** in the category of (semi-)rings, iff it is a homomorphism of (semi-)rings, such that for any (semi-)ring $(Q,+,\cdot)$ and any two homomorphisms α, $\beta : Q \to R$ of (semi-)rings we would have the implication

$$\varphi\alpha = \varphi\beta \quad \Longrightarrow \quad \alpha = \beta$$

Likewise $\varphi : R \to S$ will be called a **epimorphism** in the category of (semi-) rings, iff it is a homomorphism of (semi-)rings, such that for any (semi-)ring $(T,+,\cdot)$ and any two homomorphisms α, $\beta : S \to T$ of (semi-)rings we would have the implication

$$\alpha\varphi = \beta\varphi \quad \Longrightarrow \quad \alpha = \beta$$

Finally $\Phi : R \to S$ is said to be an **isomorphism** in the category of (semi-) rings, iff it is a homomorphism of (semi-)rings and there is another homomorphism $\Psi : S \to R$ of (semi-)rings that is inverse to Φ

$$\exists\, \Psi : S \to R \;\; : \;\; \Psi\Phi = \mathbb{1}_R \text{ and } \Phi\Psi = \mathbb{1}_S$$

It is immediately clear that an injective homomorphism of (semi-)rings thereby is a monomorphism in the categorial sense. And likewise a surjective homomorphism of (semi-rings) is an epimorphism in the categorial sense. The converse implications need not be true however. Yet we have seen in the previous proposition that the two notions of isomorphy are equivalent.

(1.83) Theorem: (viz. 739) **Isomorphism Theorems**

(i) Let $(R,+,\cdot)$ and $(S,+,\cdot)$ be any two rings, $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be an ideal of R and $\varphi : R \to S$ be a homomorphism of rings. If now $\mathfrak{a} \subseteq \ker(\varphi)$ then we obtain a well-defined homomorphism of rings by virtue of the following definition

$$\widetilde{\varphi} \;:\; R\big/_{\mathfrak{a}} \to S \;:\; b + \mathfrak{a} \mapsto \varphi(a)$$

Note that in case R and S are semi-rings only and φ is a homomorphism of such, then $\widetilde{\varphi}$ still is a well-defined homomorphism of semi-rings.

(ii) **First Isomorphism Theorem**
Let $(R,+,\cdot)$ and $(S,+,\cdot)$ be any two rings and $\varphi : R \to S$ be a homomorphism of rings. Then the kernel of φ is an ideal $\ker(\varphi) \trianglelefteq_{\mathrm{i}} R$ of R and the its image $\mathrm{im}(\varphi) \leq_{\mathrm{r}} S$ is a sub-ring of S. And finally we obtain the following isomorphy of rings

$$R\big/_{\ker(\varphi)} \;\cong_{\mathrm{r}}\; \mathrm{im}(\varphi) \;:\; a + \ker(\varphi) \mapsto \varphi(a)$$

Note that in case R and S are semi-rings only and φ is a homomorphism of such, then we still get $\ker(\varphi) \trianglelefteq_{\mathrm{i}} R$, $\mathrm{im}(\varphi) \leq_{\mathrm{s}} S$ and $R/\mathfrak{a} \cong_{\mathrm{s}} \mathrm{im}(\varphi)$.

(iii) **Second Isomorphism Theorem**

Let $(S,+,\cdot)$ be a ring, $R \leq_{\mathrm{r}} S$ be a sub-ring of S and $\mathfrak{b} \trianglelefteq_{\mathrm{i}} S$ be an ideal of S. Then $\mathfrak{b} \cap R \trianglelefteq_{\mathrm{i}} R$ is an ideal of R, the set $\mathfrak{b} + R := \{\, b + a \mid b \in \mathfrak{b}, a \in R \,\} \leq_{\mathrm{r}} S$ is a sub-ring of S and $\mathfrak{b} \trianglelefteq_{\mathrm{i}} \mathfrak{b} + R$ is an ideal of $\mathfrak{b} + R$. And thereby we obtain the following isomorphy of rings

$$R \Big/ \mathfrak{b} \cap R \;\cong_{\mathrm{r}}\; \mathfrak{b} + R \Big/ \mathfrak{b} \;:\; a + \mathfrak{b} \cap R \mapsto a + \mathfrak{b}$$

Note that in case S is a semi-ring and $R \leq_{\mathrm{s}} S$ is a sub-semi-ring of S, then still $\mathfrak{b} + R \leq_{\mathrm{s}} S$, $\mathfrak{b} \trianglelefteq_{\mathrm{i}} \mathfrak{b} + R$ and we retain the isomorphy $R/\mathfrak{b} \cap R \cong_{\mathrm{s}} \mathfrak{b} + R/\mathfrak{b}$.

(iv) **Third Isomorphism Theorem**

Let $(R,+,\cdot)$ be any ring containing the ideals $\mathfrak{a} \subseteq \mathfrak{b} \trianglelefteq_{\mathrm{i}} R$, then $\mathfrak{b}/\mathfrak{a} := \{\, b + \mathfrak{a} \mid b \in \mathfrak{b} \,\} \trianglelefteq_{\mathrm{i}} R/\mathfrak{a}$ is an ideal of the quotient ring $R/\mathfrak{a}$ and we obtain the following isomorphy of rings

$$R/\mathfrak{a} \Big/ \mathfrak{b}/\mathfrak{a} \;\cong_{\mathrm{r}}\; R \Big/ \mathfrak{b} \;:\; (a + \mathfrak{a}) + \mathfrak{b} \Big/ \mathfrak{a} \mapsto a + \mathfrak{b}$$

Note in case R is a semi-ring then everything remains the same, except that the above isomorphy is an isomorphy of semi-rings (and not necessarily of rings).

1.8 Ordered Rings

In this section we will regard commutative rings that are subjected to a (as we call it) *positive* order. However it is completely independent of the other sections within this book. Its results will neither be used nor continued elsewhere. But as it is a nice generalization of the classical examples of rings – foremost $\mathbb{Z}$, as these carry a natural order – we chose to include it nevertheless. Enjoy.

(1.84) Definition:
Let $(R, +, \cdot)$ be a commutative ring, then a subset $C \subseteq R$ is said to be a **positive cone** in R, iff it satisfies the following three properties

(C1) $0, 1 \in C$

(C2) $a, b \in C \implies a + b \in C$

(C3) $a, b \in C \implies a \cdot b \in C$

Let us denote $-C := \{ -a \mid a \in C \} \subseteq R$, then a positive cone $C \subseteq R$ is said to be **proper** iff it also satisfies the following fourth property

(CP) $C \cap (-C) = \{0\}$

And a positive cone $C \subseteq R$ is said to be **total** iff it satisfies another property

(CT) $C \cup (-C) = R$

(1.85) Proposition: (viz. 740)

(i) Let $(R, +, \cdot)$ be a commutative ring and (C_i) be a family ($i \in I$) of positive cones $C_i \subseteq R$ of R, then their intersection is a positive cone in R again

$$\bigcap_{i \in I} C_i \subseteq R \text{ is a positive cone}$$

(ii) Due to (i) we may define the positive cone **generated** by any subset $A \subseteq R$ to be the smallest positive cone containing A, that is

$$\operatorname{cone}(A) := \bigcap \{ C \subseteq R \mid A \subseteq C, C \text{is a positive cone} \}$$

(iii) Let both $(R, +, \cdot)$ and $(S, +, \cdot)$ be commutative rings and $\varphi : R \to S$ be a ring homomorphism, then we get the following implications:

$$\begin{aligned} C \subseteq R \text{ positive cone} &\implies \varphi(C) \subseteq S \text{ positive cone} \\ D \subseteq S \text{ positive cone} &\implies \varphi^{-1}(D) \subseteq R \text{ positive cone} \end{aligned}$$

(1.86) Example: (viz. 740)

(i) For any commutative ring $(R,+,\cdot)$ the whole set $R \subseteq R$ is a cone in R. In fact any sub-ring $S \subseteq R$ is a cone in R. The difference between these two notions is that a sub-ring S has to be a subgroup of the additive group $(R,+)$ of the ring, whereas a positive cone $C \subseteq R$ only is s submonoid of $(R,+)$. In fact sub-rings yield rather uninteresting positive cones.

(ii) For any commutative ring $(R,+,\cdot)$ and any $1 \leq k \in \mathbb{N}$ we can interpret k as an element of R as $k_R := 1_R + \cdots + 1_R$ (k-times) and likewise for negative numbers: $(-k)_R := -(k_R)$. Then we can regard the ring homomorphism $\zeta : \mathbb{Z} \to R : k \mapsto k_R$. The image of $\mathbb{N}$ under this homomorphism is a positive cone in R

$$P \;:=\; \{\, k_R \mid k \in \mathbb{N} \,\}$$

In fact P is the smallest positive cone of R at all [that is $P = \mathrm{cone}(\emptyset)$] and hence also called the *prime cone* of R. The homomorphism has another interesting property: The kernel of ζ is an ideal in $\mathbb{Z}$ and hence there is an unique $c \in \mathbb{N}$ such that $\mathrm{kn}(\zeta) = c\,\mathbb{Z}$. This c is called the *characteristic* of R and denoted by

$$\textsc{char}(R) \;:=\; \min\{\, k \in \mathbb{N} \mid k_R = 0 \,\}$$

(iii) A special case of the above is $\mathbb{N} \subseteq \mathbb{Z}$, which obviously is a proper, total, positive cone. Note however that $\mathbb{N} \subseteq \mathbb{Q}$ is a proper, positive cone, that is *not* total.

(iv) Another well-known example is $\mathbb{R}^+ \subseteq \mathbb{C}$, which is another proper, positive, but not total cone.

(v) Generally let $(R,+,\cdot)$ be a commutative ring under a fixed positive order $\leq$ (see below), then we obtain a proper, positive cone by letting

$$R^+ \;:=\; \{\, a \in R \mid a \geq 0 \,\}$$

(vi) If $(R,+,\cdot)$ is any commutative ring, then we obtain a positive cone Δ on R (not necessarily proper nor total) by letting

$$\Delta \;:=\; \left\{\, a_1^2 + \cdots + a_n^2 \mid n \in \mathbb{N},\ a_k \in R \,\right\}$$

(vii) Let now $(R,+,\cdot)$ be an integral domain under a fixed positive order $\leq$ (see below) and consider the polynomial ring $R[x]$ over R. If $0 \neq f \in R[x]$ is any non-zero polynomial, then there are uniquely determined $k \leq n \in \mathbb{N}$ such that f is if the form:

$$f(x) \;=\; a_n x^n + \cdots + a_k x^k$$

with $a_n \neq 0$ and $a_k \neq 0$. Thereby a_n is called the *leading coefficient* of $f(x)$ whereas a_k is said to be the the *minor coefficient* of $f(x)$ which we denote by

$$\begin{aligned} \mathrm{lc}(f) &:= a_n \\ \mathrm{mc}(f) &:= a_k \end{aligned}$$

And particularly for $f = 0$ we let $\mathrm{lc}(0) := 0$ and $\mathrm{mc}(0) := 0$. It is well known that both of these maps are multiplicative and therefore we obtain two proper, positive cones, by letting:

$$\begin{aligned} R[x]^+ &:= \{ f \in R[x] \mid \mathrm{lc}(f) \geq 0 \} \\ R[x]^- &:= \{ f \in R[x] \mid \mathrm{mc}(f) \geq 0 \} \end{aligned}$$

Note that the order on $R[x]$ induced by the cone $R[x]^+$ is *non-archimedian* as for any $2 \leq n \in \mathbb{N}$ we get $x < 1/n$. This is not so with the cone $R[x]^-$ however.

(1.87) Definition:
Let $(R, +, \cdot)$ be a commutative ring and consider a partial order $\leq$ on R. That is $\leq$ is a subset of $R \times R$ satisfying the following three properties:

(O1) $\forall\, a \in R$ we have: $a \leq a$

(O2) $\forall\, a, b \in R$ we have: If $a \leq b$ and $b \leq c$ then $a \leq c$

(O3) $\forall\, a, b \in R$ we have: If $a \leq b$ and $b \leq a$ then $a = b$

Thereby we already used the customary notation $a \leq b$ for $(a, b) \in \leq$. And as usual we write $a < b$ to denote that $a \leq b$ but $a \neq b$. Now $\leq$ is said to be a **positive** order, iff for any a, $b \in R$ we get

(P1) $0 \leq 1$

(P2) $a \leq b \iff 0 \leq b - a$

(P3) $0 \leq a, b \implies 0 \leq a + b$

(P4) $0 \leq a, b \implies 0 \leq ab$

A partial order is said to be **total** iff it further satisfies the following property

(T) $\forall\, a \in R$ we have $a \leq b$ or $b \leq a$

As usual, in this case, we may define the *minimum* $a \wedge b$ and *maximum* $a \vee b$ of a, $b \in R$ to be $a \wedge b := a$ if $a \leq b$ and $a \wedge b := b$ if $b \leq a$. Likewise $a \vee b := b$ if $a \leq b$ and $a \vee b := a$ if $b \leq a$. And we can further define the **sign** $\mathrm{sgn}(a) \in R$ and **absolute value** $|a| \in R$ of an element $a \in R$

$$\mathrm{sgn}(a) := \begin{cases} 1 \text{ if } a > 0 \\ 0 \text{ if } a = 0 \\ -1 \text{ if } a < 0 \end{cases}$$

$$|a| := \begin{cases} a \text{ if } 0 \leq a \\ -a \text{ if } a \leq 0 \end{cases}$$

(1.88) Remark:
If $\leq$ is a positive order on the commutative ring $(R, +, \cdot)$ then it already satisfies the following, stronger properties for any a, b and $h \in R$

(P5) $a < b \iff 0 < b - a$

(P6) $a \leq 0 \iff 0 \leq -a$

(P7) $a \leq b \implies a + h \leq b + h$

(P8) $a \leq b, 0 \leq h \implies ah \leq bh$

(P9) $a \leq b, h \leq 0 \implies ah \geq bh$

Prob (P5) $a < b$ means $a \leq b$ but $a \neq b$. By property (P2) we get $0 \leq b - a$. Suppose $0 = b - a$, then $a = b$, which leaves $0 < b - a$ only. (P6) this is property (P2) applied to $b = 0$, (P7) if $a \leq b$ then $0 \leq b - a = (b + h) - (a + h)$ and hence - by (P2) again - $a + h \leq b + h$. (P8) if $a \leq b$ then $0 \leq b - a$ and as also $0 \leq h$ property (P4) yields $0 \leq (b - a)h = bh - ah$. Now by (P2) again $ah \leq bh$. If $h \leq 0$ then by (P6) we have $0 \leq -h$ and hence by (P8) $a(-h) \leq b(-h)$ and hence $-ah \leq -bh$. By adding $ah + bh$ and using (P7) this yields $bh \leq ah$.

(1.89) Proposition: (viz. 741)
Let $(R, +, \cdot)$ be a commutative ring and $\leq$ be a total, positive order on R. Then for any a, $b \in R$ we get the following statements

(i) $0 \leq |a|$

(ii) $a \leq |a|$

(iii) $|a|^2 = a^2$

(iv) $|a| = \mathrm{sgn}(a)a$

Now suppose that R even is an integral domain, then we get the additional properties for any a, $b \in R$

(v) $|ab| = |a||b|$

(vi) $|a + b| \leq |a| + |b|$

(vii) $||a| - |b|| \leq |a - b|$

(viii) $\mathrm{sgn}(ab) = \mathrm{sgn}(a)\mathrm{sgn}(b)$

(ix) if $a, b \geq 0$ then $a \leq b \iff a^2 \leq b^2$

(1.90) Remark:

(i) Due to property (P2) it suffices to designate the *positive* elements of R, that is those $a \in R$ with $0 \leq a$. This fully defines the order $\leq$. Hence we denote the set of positive elements of R by R^+

$$R^+ := \{ a \in R \mid a \geq 0 \}$$

And as we have seen in the example (1.86) above, the set R^+ is a proper positive cone of R.

(ii) If $\leq$ is a *total* positive order on the commutative ring R, then the positive cone $R^+ \subseteq R$ already contains all the squares of elements of R, that is

$$\forall\, a \in R \;\; : \;\; a^2 \in R^+$$

Prob if $a \geq 0$ then $a^2 = a \cdot a \geq 0$ is trivial by property (P4). Otherwise (as $\leq$ is total) we have $a \leq 0$ such that by (P7) we get $0 \leq -a$ and hence $0 \leq (-a)(-a) = a^2$ by (P2) again. Thus $a^2 \geq 0$ is true in any case, for any $a \in R$.

(iii) If $R \neq 0$ is a non-zero ring, that allows a positive order $\leq$, then R already is of characteristic 0, that is the following map is injective

$$\mathbb{Z} \to R \;:\; k \mapsto k\,1_R$$

Prob suppose there was some $n \in \mathbb{Z}$ such that $n1_R = 0$, even though $n \neq 0$. Then we may take $n \geq 1$ to be minimal (i.e. n generates the kernel $n\mathbb{Z} = \mathrm{kn}(k \mapsto k1_R)$). As $0_R \leq 1_R$ we find $1_R \leq 2_R$ and so on until $(n-1)_R \leq n_R$. Hence $0_R \leq 1_R \leq n_R = 0_R$, which yields $0_R = 1_R$, a contradiction to $R \neq 0$. Hence the kernel of $k \mapsto k1_R$ is zero, the map is injective.

(iv) $(\diamondsuit)$ If R is a commutative ring, $\leq$ is a positive order on R and M is an R-module, then there is the notion of a cone C in M: That is a subset $C \subseteq M$ is said to be a **cone** in M, iff

(1) $0 \in C$

(2) for all $x, y \in C$ we get $x + y \in C$

(3) for all $x \in C$ and all $a \geq 0$ we get $ax \in C$

If we consider R itself as an R-module then a positive cone $C \subseteq R$ in the ring R need not be a cone in the R-module R, however. As an example let us regard $R = \mathbb{R}$ under the usual order $\leq$, then $C = \mathbb{N} \subseteq \mathbb{R}$ is a positive cone, but not a cone (in the sense of mudules).

(1.91) Example: (viz. 742)

(i) If $(R, +, \cdot)$ is a commutative ring and $C \subseteq R$ is a proper positive cone in R, then we obtain a positive order on R by letting:

$$a \leq b \quad :\Longleftrightarrow \quad b - a \in C$$

(ii) Let $R := \mathbb{Z}^2$ be the 2-dimensional lattice under the point-wise operations, that is $(a,b) + (c,d) := (a + c, b + d)$ and $(a,b)(c,d) := (ac, bd)$. We install the following partial $\leq$ order on R. Then $\leq$ is a positive order on R even though R is *not* an integral domain.

$$(a,b) \leq (c,d) \quad :\Longleftrightarrow \quad a \leq c \text{ and } b \leq d$$

(iii) The natural order $0 < 1 < 2 < 3$ on $R = \mathbb{Z}_4$ is *not* positive, as we have $2 \leq 3$ but adding $1 \geq 0$ this turns into $2 + 1 = 3 > 0 = 3 + 1$.

(1.92) Proposition: (viz. 742)
Let $(R,+,\cdot)$ be a commutative ring, then we obtain a 1-to-1 correspondence between the proper positive cones C in R and the positive orders $\leq$ on R, by virtue of

$$\begin{array}{rcl} \{\, C \subseteq R \mid C \text{ proper positive cone} \,\} & \longleftrightarrow & \{\, \leq \subseteq R \times R \mid \leq \text{ positive order} \,\} \\ C & \mapsto & (a \leq b :\Longleftrightarrow b - a \in C) \\ R^+ = \{\, a \in R \mid a \geq 0 \,\} & \mapsfrom & \leq \end{array}$$

(1.93) Proposition: (viz. 742) ($\diamondsuit$)
Let $(R,+,\cdot)$ be a commtative ring, $\leq$ be a positive order on R and let N denote the set of positive non-zero divisors of R, that is

$$N := \{\, n \in R \mid n \geq 0 \text{ and } \forall\, a \in R : an = 0 \implies a = 0 \,\}$$

Then N is multiplicatively closed and we denote the localization of R in N by $Q := N^{-1}R$. Thereby we obtain a positive order on Q, by letting

$$\frac{a}{m} \leq \frac{b}{n} \quad :\Longleftrightarrow \quad an \leq bm$$

1.9 Products

(1.94) Definition:
Let $\emptyset \neq I$ be an arbitrary set and for any $i \in I$ let $(R_i, +, \cdot)$ be a semi-ring. Then we define the **(exterior) direct product** of the R_i to be just the cartesian product of the sets R_i

$$\prod_{i \in I} R_i \;:=\; \left\{ a : I \to \bigcup_{i \in I} R_i \;\middle|\; \forall\, i \in I : a(i) \in R_i \right\}$$

Let us abbreviate this set by ΠR for a moment. Then we may turn this set into a semi-ring $(\Pi R, +, \cdot)$ by defining the following addition $+$ and multiplication $\cdot$ for elements a and $b \in \Pi R$

$$a + b \;:\; I \to \bigcup_{i \in I} R_i \;:\; i \mapsto a(i) + b(i)$$

$$a \cdot b \;:\; I \to \bigcup_{i \in I} R_i \;:\; i \mapsto a(i) \cdot b(i)$$

Note that thereby the addition $a(i) + b(i)$ and multiplication $a(i)b(i)$ are those of R_i. Further note that it is customary to write (a_i) instead of $a \in \Pi R$, where the $a_i \in R_i$ are given to be $a_i := a(i)$. And using this notation the above definitions of $+$ and $\cdot$ in ΠR take the more elegant form

$$\begin{aligned} (a_i) + (b_i) &:= (a_i + b_i) \\ (a_i) \cdot (b_i) &:= (a_i \cdot b_i) \end{aligned}$$

For any $i \in I$ let us now denote the zero-element of the semi-ring R_i by 0_i. Then we define the **(exterior) direct sum** of the R_i to be the subset of those $a = (a_i) \in \Pi R$ for which only finitely many a_i are non-zero. In formal terms this is

$$\bigoplus_{i \in I} R_i \;:=\; \left\{ a \in \prod_{i \in I} R_i \;\middle|\; \#\{\, i \in I \mid a(i) \neq 0_i \,\} < \infty \right\}$$

Let us denote this set by ΣR for the moment, then $\Sigma R \;\leq_s\; \Pi R$ is a sub-semi-ring. In particular we will always understand ΠR and ΣR as semi-rings under these compositions, without explicitly mentioning it.

(1.95) Example:

- Probably the most important case is where only two (semi-)rings $(R, +, \cdot)$ and $(S, +, \cdot)$ are involved. In this case the direct product and direct sum coincide, to be the cartesian product

 $$R \oplus S \;=\; R \times S \;=\; \{\, (a, b) \mid a \in R,\; b \in S \,\}$$

 And if we write out the operations on $R \oplus S$ explicitly (recall that these were defined to be the point-wise operations) these simply read as (where a, $b \in R$ and r, $s \in S$)

 $$\begin{aligned} (a, r) + (b, s) &= (a + b, r + s) \\ (a, r)(b, s) &= (ab, rs) \end{aligned}$$

Thereby it is clear that the zero-element of $R \oplus S$ is given to be $0 = (0,0)$. And if both R and S are rings then the unit element of $R \oplus S$ is given to be $1 = (1,1)$. It also is clear that $R \oplus S$ is commutative iff both R and S are such. The remarks below just generalize these observations and give hints how these can be proved.

- Another familiar case is the following: Consider a (semi-)ring $(R, +, \cdot)$ and any non-empty index set $I \neq \emptyset$. In the examples of section 1.4 we have already studied the (semi-)ring

$$R^I := \prod_{i \in I} R = \{ f \mid f : I \to R \}$$

 In the previous example as well as in this definition here we have taken the point-wise operations. That is for two elements $f, g : I \to R$ we have defined the operations

$$\begin{aligned} f + g : I \to R &= i \mapsto f(i) + g(i) \\ fg : I \to R &= i \mapsto f(i) \cdot g(i) \end{aligned}$$

 And it is clear that the zero-element is given to be the constant function $0 : I \to R : i \mapsto 0$. And if R is a ring then we also have a unit element given to be the constant function $1 : I \to R : i \mapsto 1$.

- We continue with the example above. Instead of the direct product we may also take to the direct sum of R over I. That is we may regard

$$R^{\oplus I} := \bigoplus_{i \in I} R = \{ f : I \to R \mid \#\mathrm{Supp}(f) < \infty \}$$

 where $\mathrm{Supp}(f) := \{i \in I \mid f(i) \neq 0\}$. It is clear $R^{\oplus I} \subseteq R^I$ truly is a subset of the direct product. But be careful, as in any non-zero ring $R \neq 0$ we have $1 \neq 0$ we find that for infinite index sets I the unit element $1 : I \to R : i \mapsto 1$ is *not* contained in $R^{\oplus I}$. That is $R^{\oplus I}$ will not be a ring unless I is finite, even if R is such.

(1.96) Remark:
As above let $\emptyset \neq I$ be an arbitray index set and for any $i \in I$ let $(R_i, +, \cdot)$ be a (semi-)ring having the zero element 0_i (and unit element 1_i if any). Then let us denote the direct product of the R_i by ΠR and the direct sum of the R_i by ΣR. Then we would like to remark the following

- It is clear that $(\Pi R, +, \cdot)$ truly becomes a (semi-)ring under the operations above. And if we denote the zero-element of any R_i by 0_i then the zero-element of ΠR is given to be $0 = (0_i)$.

 Prob one easily checks all the properties required for a semi-ring. As an example we prove the associativity of the addition: Let $a = (a_i)$, $b = (b_i)$ and $c = (c_i) \in \Pi R$, then $((a+b)+c)_i = (a+b)_i + c_i = (a_i + b_i) + c_i = a_i + (b_i + c_i) = a_i + (b+c)_i = (a + (b+c))_i$.

- Clearly ΠR is commutative if and only if R_i is commutative for any $i \in I$. And ΠR is a ring if and only if R_i is a ring for any $i \in I$. In the latter case let us denote the unit element of R_i by 1_i. Then the unit element of ΠR is given to be $1 = (1_i)$.

Prob if all the R_i are commutative, then for any $a = (a_i)$, $b = (b_i) \in \Pi R$ we immediately see the commutativity $(ab)_i = a_i b_i = b_i a_i = (ba)_i$ of ΠR. If any R_i is a ring then for any $a = (a_i) \in \Pi R$ we get $(1a)_i = 1_i a_i = a_i$ and $(a1)_i = a_i 1_i = a_i$. And if ΠR is a ring, fix any $j \in I$ and let $a_i := 0$ for any $j \neq i \in I$. Then the same argument shows, that R_j commutative resp. is a ring.

- By definition $\Sigma R \subseteq \Pi R$ is a subset. But ΣR even is a sub-semi-ring $\Sigma R \leq_s \Pi R$ of ΠR. Yet ΣR need *not* be a sub-ring of ΠR (even if any R_i is a ring), as (1_i) need not be contained in ΣR.

 Prob consider any $a = (a_i)$ and $b = (b_i) \in \Sigma R$ and let us denote the set $S(a) := \{ i \in I \mid a_i \neq 0_i \}$. E.g. we get $S(0) = \emptyset$ and hence $0 \in \Sigma R$. Further it is clear that $S(a+b) \subseteq S(a) \cup S(b)$, $S(-a) = S(a)$ and $S(ab) \subseteq S(a) \cap S(b)$. In particular all these sets are finite again and hence $a+b$, $-a$ and $ab \in \Sigma R$, which had to be shown.

- Note that we get $\Sigma R = \Pi R$ if and only if I is a finite set. And in the case of finitely many semi-rings $R_1, \ldots, R_n$ we also use the slightly lax notation (note that thereby $R_1 \times \cdots \times R_n = R_1 \oplus \cdots \oplus R_n$)

$$\begin{aligned} R_1 \times \cdots \times R_n &:= \prod_{i=1}^{n} R_i \\ R_1 \oplus \cdots \oplus R_n &:= \bigoplus_{i=1}^{n} R_i \end{aligned}$$

- It is clear that the product of (semi-)rings is associative and commutative up to isomorphy. That is if we consider the (semi-)rings $(R, +, \cdot)$, $(S, +, \cdot)$ and $(T, +, \cdot)$, then we obtain the following isomorphies of (semi-)rings

$$\begin{aligned} R \oplus S &\cong_s S \oplus R &&: (a,b) \mapsto (b,a) \\ \big(R \oplus S\big) \oplus T &\cong_s R \oplus \big(S \oplus T\big) &&: \big((a,b),c\big) \mapsto \big(a,(b,c)\big) \end{aligned}$$

 Prob it is immediately clear that the above mappings are homomorphisms of (semi-)rings by definition of the operations on the product. And likewise it is clear (this is an elementary property of cartesian products) that these mappings also are bijective.

- Yet ΠR usually does *not* inherit any nice properties from the R_i, except being commutative or a ring. E.g. $\mathbb{Z}$ is an integral domain, but $\mathbb{Z}^2 = \mathbb{Z} \times \mathbb{Z}$ contains the zero-divisors $(1,0)$ and $(0,1)$.

- For any $j \in I$ let us denote the canonical projection from ΠR (or ΣR respectively) by π_j. Likewise let ι_j denote the canonical injection of R_j into ΠR (or ΣR respectively). That is we let

$$\pi_j : \Sigma R \twoheadrightarrow R_j : (a_i) \mapsto a_j$$

$$\iota_j : R_j \hookrightarrow \Sigma R : a_j \mapsto \left(i \mapsto \begin{cases} a_j \text{ if } i = j \\ 0_i \text{ if } i \neq j \end{cases} \right)$$

 Then it is clear that π_i and ι_j are homomorphisms of semi-rings satisfying $\pi_j \iota_j = \mathbb{1}_j$. In particular π_j is surjective and ι_j is injective. And we will often interpret R_j as a sub-semi-ring of ΠR (or ΣR respectively) by using the isomorphism $\iota_j : R_j \cong_s \operatorname{im}(\iota_j)$.

(1.97) Proposition: (viz. 743) ($\diamondsuit$)
Let $(R,+,\cdot)$ and $(S,+,\cdot)$ be any commutative rings and consider the ideals $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ and $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$. Then we obtain an ideal $\mathfrak{a} \oplus \mathfrak{b}$ of $R \oplus S$ by letting

$$\mathfrak{a} \oplus \mathfrak{b} \;:=\; \{\, (a,b) \mid a \in \mathfrak{a},\ b \in \mathfrak{b} \,\}$$

Conversely let us denote the canonical projection of $R \oplus S$ to R by $\varrho : R \oplus S \twoheadrightarrow R : (a,b) \mapsto a$ and to S by $\sigma : R \oplus S \twoheadrightarrow S : (a,b) \mapsto b$ respectively. If now $\mathfrak{u} \trianglelefteq_{\mathrm{i}} R \oplus S$ is an ideal then we get the identity

$$\mathfrak{u} \;=\; \varrho(\mathfrak{u}) \oplus \sigma(\mathfrak{u})$$

And thereby we obtain an explicit description of all ideals (respectively of all radical, prime or maximal) ideals of $R \oplus S$. These are given to be the following

$$\begin{aligned}
\mathrm{Ideal}(R \oplus S) &= \{\, \mathfrak{a} \oplus \mathfrak{b} \mid, \mathfrak{a} \in \mathrm{Ideal}(R),\ \mathfrak{b} \in \mathrm{Ideal}(S) \,\} \\
\mathrm{Srad}(R \oplus S) &= \{\, \mathfrak{a} \oplus \mathfrak{b} \mid, \mathfrak{a} \in \mathrm{Srad}(R),\ \mathfrak{b} \in \mathrm{Srad}(S) \,\} \\
\mathrm{Spec}(R \oplus S) &= \{\, \mathfrak{p} \oplus S \mid \mathfrak{p} \in \mathrm{Spec}(R) \,\} \cup \{\, R \oplus \mathfrak{q} \mid \mathfrak{q} \in \mathrm{Spec}(S) \,\} \\
\mathrm{Smax}(R \oplus S) &= \{\, \mathfrak{m} \oplus S \mid \mathfrak{m} \in \mathrm{Smax}(R) \,\} \cup \{\, R \oplus \mathfrak{n} \mid \mathfrak{n} \in \mathrm{Smax}(S) \,\}
\end{aligned}$$

(1.98) Remark: ($\diamondsuit$)
For any $i \in 1 \ldots n$ let $(R_i,+,\cdot)$ be a commutative ring and let $R := R_1 \oplus \cdots \oplus R_n$ abbreviate their direct sum. Then by induction on n we find the following pairs of equivalent statements from (1.97)

$$\begin{aligned}
\mathfrak{a} \trianglelefteq_{\mathrm{i}} R \quad &\Longleftrightarrow \quad \exists\, \mathfrak{a}_k \trianglelefteq_{\mathrm{i}} R_k \text{ (where } k \in 1 \ldots n) \;:\; \mathfrak{a} = \bigoplus_{k=1}^{n} \mathfrak{a}_k \\
\mathfrak{a} \in \mathrm{Srad}(R) \quad &\Longleftrightarrow \quad \exists\, \mathfrak{a}_k \in \mathrm{Srad}(R_k) \text{ (where } k \in 1 \ldots n) \;:\; \mathfrak{a} = \bigoplus_{k=1}^{n} \mathfrak{a}_k \\
\mathfrak{p} \in \mathrm{Spec}(R) \quad &\Longleftrightarrow \quad \exists\, m \in 1 \ldots n \;\; \exists\, \mathfrak{p}_m \in \mathrm{Spec}(R_k) \;:\; \mathfrak{p} = \bigoplus_{k=1}^{n} \begin{cases} \mathfrak{p}_m \text{ if } k = m \\ R_k \text{ if } k \neq m \end{cases} \\
\mathfrak{m} \in \mathrm{Smax}(R) \quad &\Longleftrightarrow \quad \exists\, m \in 1 \ldots n \;\; \exists\, \mathfrak{m}_m \in \mathrm{Smax}(R_k) \;:\; \mathfrak{m} = \bigoplus_{k=1}^{n} \begin{cases} \mathfrak{m}_m \text{ if } k = m \\ R_k \text{ if } k \neq m \end{cases}
\end{aligned}$$

(1.99) Theorem: (viz. 744)

(i) Consider any commutative ring $(R,+,\cdot)$ and two elements $e, f \in R$. Further let us denote the respective principal ideals by $\mathfrak{a} := eR$ and $\mathfrak{b} := fR$. If now e and f satisfy $e + f = 1$ and $ef = 0$ then we get $\mathfrak{a} + \mathfrak{b} = R$ and $\mathfrak{a} \cap \mathfrak{b} = \{0\}$, formally that is

$$e + f = 1,\ ef = 0 \quad \Longrightarrow \quad \mathfrak{a} + \mathfrak{b} = R,\ \mathfrak{a} \cap \mathfrak{b} = \{0\}$$

(ii) More generally let $(R,+,\cdot)$ be a commutative ring and $e_1,\ldots,e_n \in R$ be a collection of elements (where $n \geq 2$), such that (1) $e_1+\cdots+e_n = 1$ and (2) for any $i \neq j \in 1\ldots n$ we get $e_ie_j = 0$, then the ideals $\mathfrak{a}_i := Re_i$ satisfy the following two properties

(1) $R = \mathfrak{a}_1+\cdots+\mathfrak{a}_n$

(2) $\mathfrak{a}_1\cap\cdots\cap\mathfrak{a}_n = \{0\}$

(iii) Now let $(R,+,\cdot)$ be any (not necessarily commutative) ring and $\mathfrak{a},\ \mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ be two ideals of R satisfying $\mathfrak{a}+\mathfrak{b} = R$ and $\mathfrak{a}\cap\mathfrak{b} = \{0\}$. Then we obtain the following isomorphy of rings

$$R \cong_{\mathrm{r}} R\Big/_{\mathfrak{a}} \oplus R\Big/_{\mathfrak{b}} \ :\ x \mapsto (x+\mathfrak{a}, x+\mathfrak{b})$$

(iv) **Chinese Remainder Theorem**
Let $(R,+,\cdot)$ be any commutative ring and consider finitely many ideals $\mathfrak{a}_i \trianglelefteq_{\mathrm{i}} R$ (where $i \in 1\ldots n$) of R, that are pairwise coprime. That is for any $i \neq j \in 1\ldots n$ we assume

$$\mathfrak{a}_i+\mathfrak{a}_j = R$$

Let us now denote the intersection of all the $\mathfrak{a}_i$ by $\mathfrak{a} := \mathfrak{a}_1\cap\cdots\cap\mathfrak{a}_n$. Then we obtain the following isomorphy of rings

$$R\Big/_{\mathfrak{a}} \cong_{\mathrm{r}} \bigoplus_{i=1}^{n} R\Big/_{\mathfrak{a}_i} \ :\ x+\mathfrak{a} \mapsto (x+\mathfrak{a}_1,\ldots,x+\mathfrak{a}_n)$$

(1.100) Remark:

- Combining (i) and (ii) we immediately see that, whenever we are given two elements $e,\ f \in R$ in a commutative ring R, such that $e+f = 1$ and $ef = 0$, then this induces a decomposition of R into

$$R \cong_{\mathrm{r}} R\Big/_{eR} \oplus R\Big/_{fR} \ :\ x \mapsto (x+eR, x+fR)$$

- Clearly (iii) is just a special case of the Chinese Remainder Theorem (iv). Nevertheless we gave a separate formulation (and proof) of the statement to be easily accessible. In fact (iii) talks about decomposing R into smaller rings, whereas (iv) is about solving equations:

- Suppose we are given elements $a_i \in R$ (where $i \in 1\ldots n$). Then the surjectivity of the isomorphism in (iii) guarantees that there is a solution $x \in R$ to the following system of congruences. And if x is any solution of this system, then due to the isomorphy in (iii) we also find that the set of all solutions is given to be $x+\mathfrak{a}$.

$$\begin{aligned} x+\mathfrak{a}_1 &= a_1+\mathfrak{a}_1 \\ &\vdots \\ x+\mathfrak{a}_n &= a_n+\mathfrak{a}_n \end{aligned}$$

- If $a, b \in \mathbb{Z}$ are relatively prime (this will be $1 \in \gcd\{a, b\}$) and $n := ab$, then $a\mathbb{Z} + b\mathbb{Z} = \mathbb{Z}$ and hence the Chinese Remainder Theorem yields the following, well-defined isomorphism of rings

$$\mathbb{Z}_n \xrightarrow{\sim} \mathbb{Z}_a \oplus \mathbb{Z}_b \ : \ k + n\mathbb{Z} \mapsto \big(k + a\mathbb{Z}, k + b\mathbb{Z}\big)$$

- However if a and $b \in \mathbb{Z}$ have a common denominator, i.e. $d \in \gcd\{a, b\}$ with $d \geq 2$ and $n := ab$ again, then $\mathbb{Z}_n$ is not isomorphic to $\mathbb{Z}_a \oplus \mathbb{Z}_b$ (not even as $\mathbb{Z}$-modules).

 Prob Let $m := ab/d$ be the least common multiple of a and b, as $d \geq 2$ we have $m < ab$. Clearly $m(k + a\mathbb{Z}, k + b\mathbb{Z}) = 0 \in \mathbb{Z}_a \oplus \mathbb{Z}_b$ as both a and b divide m. In particular $\operatorname{ord}(k + a\mathbb{Z}, k + b\mathbb{Z}) \leq m$ and therefore $\mathbb{Z}_a \oplus \mathbb{Z}_b$ has elements of order m, at most. On the other hand $1 + n\mathbb{Z} \in \mathbb{Z}_n$ has order $\operatorname{ord}(1 + n\mathbb{Z}) = n = ab > m$. That is $\mathbb{Z}_n$ has an element of higher order, than any element of $\mathbb{Z}_a \oplus \mathbb{Z}_b$. In particular $\mathbb{Z}_n$ and $\mathbb{Z}_a \oplus \mathbb{Z}_b$ can't be isomorphic (as $\mathbb{Z}$-modules).

- $(\diamondsuit)$ Let us consider an example of the above in the integers $R := \mathbb{Z}$. Let $\mathfrak{a}_1 := 8\mathbb{Z}$ and $\mathfrak{a}_2 := 15\mathbb{Z}$. As 8 and 15 are relatively prime we truly find $\mathfrak{a}_1 + \mathfrak{a}_2 = \mathbb{Z}$. And also $\mathfrak{a} = \mathfrak{a}_1 \cap \mathfrak{a}_2 = 120\mathbb{Z}$, since the least common multiple of 8 and 15 is 120. It is elementary to verify the following congruences

$$\begin{array}{rclcrcl} 105 + 8\mathbb{Z} & = & 1 + 8\mathbb{Z} & \qquad & 16 + 8\mathbb{Z} & = & 0 + 8\mathbb{Z} \\ 105 + 15\mathbb{Z} & = & 0 + 15\mathbb{Z} & & 16 + 15\mathbb{Z} & = & 1 + 15\mathbb{Z} \end{array}$$

 Hence if we are given any $a_1, a_2 \in \mathbb{Z}$ then we let $x := 105a_1 + 16a_2 \in \mathbb{Z}$ to solve the general system of congruences

$$\begin{array}{rcl} x + 8\mathbb{Z} & = & a_1 + 8\mathbb{Z} \\ x + 15\mathbb{Z} & = & a_2 + 15\mathbb{Z} \end{array}$$

Chapter 2

Commutative Rings

2.1 Maximal Ideals

Non-commutative rings can be tedious. There's quite some theory concerned with rings, that defy commutativity, especially in presence of some further assumptions, e.g. Lie algebras or Jordan algebras. But in general its hard to squeeze some general structure from non-commutative rings. Yet in the case of commutative rings, the story is quite different. These rings can display astoundingly rich structures that allow beautiful classifications. The integers are the classical example, they allow prime factorization due to division with remainder. But the same is true for polynomial rings. Here we already see that there have to be some underlying reasons for this similarity.
Historically speaking ideals have been introduced to be *ideal numbers* that have even better properties, than the numbers themselves. And the main reason why commutative rings are better behaved than non-commutative is that in the former case any ideal is contained in a maximal ideal. Translated into divisibility of numbers this means that any (non-unit) number has a prime divisor. In the non-commutative case (in modules) this is not always the case.
This seemingly insignificant property is the staging area of the vast theory with which we want to proceed. So the first task will be to introduce maximal ideals and study their basic properties. To do this we recollect and append some notions of section 0.4 in order to apply it to the case of ideals later.

(2.1) Remark: (viz. 747)

(i) Let us first recall the definition of a **partial order** on some non-empty set $X \neq \emptyset$. This is a relation $\leq$ on X [that is a subset of the form $\leq \subseteq X \times X$] such that for any x, y and $z \in X$ we get

$$\begin{aligned} x = y &\implies x \leq y \\ x \leq y,\ y \leq z &\implies x \leq z \\ x \leq y,\ y \leq x &\implies x = y \end{aligned}$$

[where we already wrote $x \leq y$ for the formal statement $(x,y) \in \leq$]. And in this case we also call $(X, \leq)$ a *partially odered set*. And in this case it is also customary to use the notation

$$x < y \quad :\Longleftrightarrow \quad x \leq y \text{ and } x \neq y$$

(ii) And $\leq$ is said to be a **linear order** on X (respectively $(X, \leq)$ is called a *linearly ordered set*), iff $\leq$ is a partial order such that any two elements of X are *comparable*, formally

$$\forall\, x, y \in X \;\; : \;\; x \leq y \text{ or } y \leq y$$

And in this case we may define the *maximum* $x \vee y$ and *minimum* of any two elements $x, y \in X$ to be the following elements of X

$$x \wedge y \;\; := \;\; \begin{cases} x \text{ if } x \leq y \\ y \text{ if } y \leq x \end{cases} \qquad x \vee y \;\; := \;\; \begin{cases} y \text{ if } x \leq y \\ x \text{ if } y \leq x \end{cases}$$

(iii) Example: If S is any set (even $S = \emptyset$ is allowed), then we may take the power set $X := \mathcal{P}(X) = \{\, A \mid A \subseteq S \,\}$ of X. Then the *inclusion relation* $\subseteq$ which is defined by

$$A \subseteq B \;\; :\Longleftrightarrow \;\; \Big(\forall\, x : x \in A \implies x \in B\Big)$$

is a partial order on S. However the inclusion $\subseteq$ almost never is a total order. E.g. regard $S := \{\, 0, 1 \,\}$. Then the elements $\{0\}$ and $\{\, 1 \,\} \in X$ of X are not comparable. In what follows we will usually consider some set $X \subseteq \mathrm{Ideal}(R) \subseteq \mathcal{P}(R)$ of ideals of a commutative ring R under the inclusion relation $\subseteq$.

(iv) Now let $(X, \leq)$ be a partially ordered set and $A \subseteq X$ be a subset. Then we define the sets A_* of *minimal* and A^* of *maximal* elements of A to be the following

$$\begin{aligned} A_* \;\; &:= \;\; \{\, a_* \in A \mid \forall\, a \in A : a \leq a_* \implies a = a_* \,\} \\ A^* \;\; &:= \;\; \{\, a^* \in A \mid \forall\, a \in A : a^* \leq a \implies a = a^* \,\} \end{aligned}$$

And an element $a_* \in A_*$ is said to be a *minimal* element of A. Likewise $a^* \in A^*$ is said to be a *maximal* element of A. Note that in general it may happen that A has several minimal (or maximal) elements or even none at all. Example: $\mathbb{N}_* = \{0\}$ and $\mathbb{N}^* = \emptyset$ under the usual order $\leq$ on $\mathbb{N}$.

(v) If $(X, \leq)$ is a linearly ordered set and $A \subseteq X$ is a subset, then maximal and minimal elements of A are uniquely determined. Formally that is

$$\begin{aligned} a, b \in A^* \quad &\implies \quad a = b \\ a, b \in A_* \quad &\implies \quad a = b \end{aligned}$$

(vi) Let again $(X, \leq)$ be a linearly ordered set and $A = \{\, a_1, \ldots, a_n \,\} \subseteq X$ be a finite subset of X. Then there is a (uniquley) determined minimal element A_* (resp. maximal element a^*) of A. And this is given to be

$$\begin{aligned} A^* &= \{\, a^* \,\} \quad \text{where} \quad a^* = \Big(\big(a_1 \vee a_2\big) \ldots\Big) \vee a_n \\ A_* &= \{\, a_* \,\} \quad \text{where} \quad a_* = \Big(\big(a_1 \wedge a_2\big) \ldots\Big) \wedge a_n \end{aligned}$$

(vii) Once again let $(X, \leq)$ be any partially ordered set and $A \subseteq X$ be a subset of X. Then it is clear that $\leq$ induces another partial order $\leq_A$ on A by restricting

$$\leq_A \ := \ (\leq) \cap (A \times A)$$

And we will write $\leq$ for $\leq_A$ again, that is we write $(A, \leq)$ instead of the more correct form $(A, \leq_A)$. Now a subset $C \subseteq X$ is said to be a **chain** in X iff $(C, \leq)$ is linearly ordered. Equivalently that is iff any two elements of C are comparable, formally

$$\forall\, x, y \in C \ : \ x \leq y \text{ or } y \leq x$$

(viii) Let us recall the **Lemma of Zorn**: Say $(X, \leq)$ is a partially ordered set (in particular $X \neq \emptyset$), such that any chain C of X has an upper bound u in X, formally

$$\forall\, C \subseteq X \ : \ C \text{ chain} \implies \exists\, u \in X\, \forall\, c \in C \ : \ c \leq u$$

Then X already contains a (not necessarily) unique maximal element - in formal terms this is

$$\exists\, x^* \in X\, \forall\, x \in X \ : \ x^* \leq x \implies x = x^*$$

Nota though it may come as a surprise the lemma of Zorn surely is the single most powerful tool in mathematics! We will see its impact on several occasions: E.g. the existence of maximal ideals or the existence of bases (in vector-spaces). We recommend taking it for granted, it is just one of the equivalent reformulations of the axiom of choice. Hence you might as well the lemma of Zorn as a set-theoretic axiom itself. In case you really want to see a proof, refer to (0.28).

(ix) In most cases we will use a quite simple form of the lemma of Zorn: Consider an arbitrary collection of sets $\mathcal{Z}$. Recall that a *chain* in $\mathcal{Z}$ is a subset $\mathcal{C} \subseteq \mathcal{Z}$ such that $\mathcal{C} \neq \emptyset$ and for any $A, B \in \mathcal{C}$ we get $A \subseteq B$ or $B \subseteq A$. Now verify that

(1) $\mathcal{Z} \neq \emptyset$ is non-empty

(2) if $\mathcal{C} \subseteq \mathcal{Z}$ is a chain, then $\bigcup \mathcal{C} \in \mathcal{Z}$ again

Then (by the lemma of Zorn, as any $C \in \mathcal{C}$ satisfies $C \subseteq \bigcup \mathcal{C}$) $\mathcal{Z}$ already contains a (not necessarily unique) $\subseteq$-maximal element $Z \in \mathcal{Z}^*$. That is for any $A \in \mathcal{Z}$ we get

$$Z \subseteq A \implies A = Z$$

(x) Of course the lemma of Zorn can also be applied to find minimal elements. In analogy to the above we obtain the following special case: Consider an arbitrary collection of sets $\mathcal{Z}$. Now verify that

(1) $\mathcal{Z} \neq \emptyset$ is non-empty

(2) if $\mathcal{C} \subseteq \mathcal{Z}$ is a chain, then $\bigcap \mathcal{C} \in \mathcal{Z}$ again

Then (by the lemma of Zorn, as any $C \in \mathcal{C}$ satisfies $\bigcap \mathcal{C} \subseteq C$) $\mathcal{Z}$ already contains a (not necessarily unique) $\subseteq$-minimal element $Z \in \mathcal{Z}_*$. That is for any $A \in \mathcal{Z}$ we get

$$A \subseteq Z \implies A = Z$$

(2.2) Definition:
Let $(R, +, \cdot)$ be a commutative ring and $\emptyset \neq \mathcal{A} \subseteq \mathrm{Ideal}(R)$ be a non-empty set of ideals of R. Then we recall the definiton of *maximal* $\mathfrak{a}^* \in \mathcal{A}^*$ and *minimal* $\mathfrak{a}_* \in \mathcal{A}_*$ elements (concerning the order "$\subseteq$") of $\mathcal{A}$:

$$\begin{aligned} \mathcal{A}^* &:= \{\, \mathfrak{a}^* \in \mathcal{A} \mid \forall\, \mathfrak{a} \in \mathcal{A} : \mathfrak{a}^* \subseteq \mathfrak{a} \implies \mathfrak{a} = \mathfrak{a}^* \,\} \\ \mathcal{A}_* &:= \{\, \mathfrak{a}_* \in \mathcal{A} \mid \forall\, \mathfrak{a} \in \mathcal{A} : \mathfrak{a} \subseteq \mathfrak{a}_* \implies \mathfrak{a} = \mathfrak{a}_* \,\} \end{aligned}$$

(2.3) Definition:
Let $(R, +, \cdot)$ be a commutative ring, then $\mathfrak{m} \subseteq R$ is said to be a **maximal ideal** of R, iff it is a maximal element of the set of all ideals but R, that is iff the following three statements hold true

(1) $\mathfrak{m}$ is an ideal: $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$

(2) $\mathfrak{m}$ is proper: $\mathfrak{m} \neq R$

(3) there is no proper ideal containing $\mathfrak{m}$, that is for any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ we find the implication

$$\mathfrak{m} \subseteq \mathfrak{a} \implies \mathfrak{a} = \mathfrak{m} \text{ or } \mathfrak{a} = R$$

The set $\mathrm{Smax}(R)$ of all maximal ideals will be called the **maximal spectrum** of R and the intersection of all maximal ideals will be called the **Jacobson radical** of R. We denote these by

$$\begin{aligned} \mathrm{Smax}(R) &:= \Big(\mathrm{Ideal}(R) \setminus \{\, R \,\}\Big)^* \\ &= \{\, \mathfrak{m} \subseteq R \mid (1), (2) \text{ and } (3) \,\} \\ \textsc{jac}(R) &:= \bigcap \mathrm{Smax}(R) \end{aligned}$$

(2.4) Lemma: (viz. 864)

(i) Let $(R, +, \cdot)$ be a commutative ring and $\emptyset \neq \mathcal{A} \subseteq \mathrm{Ideal}(R)$ be a chain of ideals (that is for any $\mathfrak{a}$, $\mathfrak{b} \in \mathcal{A}$ we have $\mathfrak{a} \subseteq \mathfrak{b}$ or $\mathfrak{b} \subseteq \mathfrak{a}$). Then the union of all the $\mathfrak{a} \in \mathcal{A}$ is an ideal of R, formally

$$\mathcal{A} \subseteq \mathrm{Ideal}(R),\ \mathcal{A} \neq \emptyset \ \text{ is a chain } \implies \bigcup \mathcal{A} \trianglelefteq_{\mathrm{i}} R \ \text{ is an ideal}$$

(ii) Let $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be any proper (that is $\mathfrak{a} \neq R$) ideal in the commutative ring $(R, +, \cdot)$, then there is a maximal ideal of R containing $\mathfrak{a}$, formally

$$\mathfrak{a} \trianglelefteq_{\mathrm{i}} R,\ \mathfrak{a} \neq R \implies \exists\, \mathfrak{m} \in \mathrm{Smax}(R) \,:\, \mathfrak{a} \subseteq \mathfrak{m}$$

(iii) In a commutative ring $(R, +, \cdot)$ the group of units R^* of R is precisely the complement of the union of all maximal ideals of R. That is we have the identity of

$$R^* \quad = \quad R \setminus \bigcup \mathrm{Smax}(R)$$

(iv) The zero-ring is the one and only ring without maximal ideals. That is the following equivalence of

$$R = 0 \quad \Longleftrightarrow \quad \mathrm{Smax}(R) = \emptyset$$

(v) A commutative ring $(R, +, \cdot)$ is a field, iff the zero ideal $0 \trianglelefteq_{\mathrm{i}} R$ is the one and only maximal ideal of R. Formally again this is the equivalence of

$$R \text{ is a field} \quad \Longleftrightarrow \quad \mathrm{Smax}(R) = \{0\}$$

(2.5) Proposition: (viz. 878)
Let $(R, +, \cdot)$ be a commutative ring and $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$ be an ideal of R. Then the following four statements concerning $\mathfrak{m}$ are equivalent

(a) $\mathfrak{m}$ is a maximal ideal

(b) the quotient ring $R/\mathfrak{m}$ is a field

(c) the quotient ring $R/\mathfrak{m}$ is *simple* - i.e. it only contains the trivial ideals: zero and the ring itself

$$\overline{\mathfrak{a}} \trianglelefteq_{\mathrm{i}} {}^{R}\!\Big/_{\mathfrak{m}} \quad \Longrightarrow \quad \overline{\mathfrak{a}} = \{\, 0 + \mathfrak{m} \,\} \text{ or } \overline{\mathfrak{a}} = {}^{R}\!\Big/_{\mathfrak{m}}$$

(d) $\mathfrak{m}$ is coprime to any principal ideal that is not already contained in $\mathfrak{m}$, formally that is: For any $a \in R$ we get the implication

$$a \notin \mathfrak{m} \quad \Longrightarrow \quad \mathfrak{m} + aR = R$$

(2.6) Remark:
In particular the above proposition can be reformulated for the zero-ideal $\mathfrak{m} = 0$. Doing this we find the equivalence of the following three statements, for any commutative ring $(R, +, \cdot)$

(a) 0 is a maximal ideal of R

(b) R is a field

(c) R is *simple*, that is: $\mathrm{Ideal}(R) = \{0, R\}$

(2.7) Example: (viz. 819)

(i) If F is a field, then any ideal of the form $(t - a\mathbf{1})F[t]$ is a maximal ideal of the polynomial ring $F[t]$. And thereby we obtain an injective (but not generally surjective) map, by

$$F \;\hookrightarrow\; \mathrm{Smax}\big(F[t]\big) \;:\; a \;\mapsto\; (t - a\mathbf{1})F[t]$$

(ii) If $(F,+,\cdot)$ is a field, then clearly $\text{JAC}(F) = 0$, as 0 is the one and only maximal ideal of F. But this even is true for the polynomial ring $F[t]$ over F, that is we also get

$$\text{JAC}\big(F[t]\big) \;=\; 0$$

(iii) $(\diamondsuit)$ Let $n \in \mathbb{N}$ have the primary decomposition $n = p_1^{k(1)} \dots p_r^{k(r)}$. Then the residue ring $\mathbb{Z}_n$ has precisely the maximal ideals $p_i\mathbb{Z}_n$ where $i \in 1 \dots r$ and thereby the Jacobson radical of $\mathbb{Z}_n$ is

$$\text{JAC}\big(\mathbb{Z}_n\big) \;=\; (p_1 \dots p_r)\mathbb{Z}_n$$

(2.8) Proposition: (viz. 879)
Let $(R,+,\cdot)$ be any commutative ring, then we can reformulate the Jacobson radical of R: For any $j \in R$ the following two statements are equivalent

(a) $j \in \text{JAC}(R)$

(b) $\forall\, a \in R$ we get $1 - aj \in R^*$

And if $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ is an ideal of R, then $\mathfrak{a}$ is contained in the Jacobson radical iff $1 + \mathfrak{a}$ is a subgroup of the multiplicative group. That is we obtain another equivalence of the statements

(a) $\mathfrak{a} \;\subseteq\; \text{JAC}(R)$

(b) $1 + \mathfrak{a} \;\subseteq\; R^*$

(c) $1 + \mathfrak{a} \;\leq_{\mathfrak{g}}\; R^*$

(2.9) Proposition: (viz. 880)
Let $(R,+,\cdot)$ be a commutative ring, let $\{\, \mathfrak{m}_1, \dots, \mathfrak{m}_r \,\} \subseteq \text{Smax}(R)$ be finitely many maximal ideals of R and $p, q \in \mathbb{N}$. Then we find the following properties

$$\forall\, i \neq j \in 1 \dots r \;\;:\;\; \mathfrak{m}_i^p + \mathfrak{m}_j^q = R$$

$$\mathfrak{m}_1 \cap \dots \cap \mathfrak{m}_r \;=\; \mathfrak{m}_1 \dots \mathfrak{m}_r$$

$$\mathfrak{m}_1 \;\supset\; \mathfrak{m}_1\mathfrak{m}_2 \;\supset\; \dots \;\supset\; \mathfrak{m}_1\mathfrak{m}_2 \dots \mathfrak{m}_r$$

(2.10) Corollary: (viz. 883)
Let $(R,+,\cdot)$ be a commutative ring and consider $\mathfrak{m}_1, \dots, \mathfrak{m}_r \in \text{Smax}(R)$ finitely many, distinct maximal ideals of R (i.e. $\mathfrak{m}_i \neq \mathfrak{m}_j$ for any $i \neq j \in 1 \dots r$). Abbreviate their intersection by $\mathfrak{j} := \mathfrak{m}_1 \cap \dots \cap \mathfrak{m}_r$ then we have the following isomorphy of rings

$$R\big/_{\mathfrak{j}} \;\cong_{\mathfrak{r}}\; \bigoplus_{i=1}^{r} R\big/_{\mathfrak{m}_i} \;:\; a + \mathfrak{j} \mapsto \Big(a + \mathfrak{m}_i\Big)$$

$$\text{Spec}\left(R\big/_{\mathfrak{j}}\right) \;=\; \text{Smax}\left(R\big/_{\mathfrak{j}}\right) \;=\; \left\{ \mathfrak{m}_i\big/_{\mathfrak{j}} \;\middle|\; i \in 1 \dots r \right\}$$

2.2 Prime Ideals

Prime ideals are another elementary concept with far-reaching consequences that can be seen as a generalization of prime numbers. In abstract algebraic geometry and number theory the set of prime ideals of a ring is the object of interest, as all many properties of the base ring reflect in there.

(2.11) Definition:
Let $(R,+,\cdot)$ be a commutative ring, then a subset $\mathfrak{p} \subseteq R$ is said to be a **prime ideal** of R, iff the following three statements hold true

(1) $\mathfrak{p}$ is an ideal: $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$

(2) $\mathfrak{p}$ is proper $\mathfrak{p} \neq R$

(3) $\forall\, a, b \in R$ we get $ab \in \mathfrak{p} \implies a \in \mathfrak{p}$ or $b \in \mathfrak{p}$

And the set $\mathrm{Spec}(R)$ of all prime ideals of R is called (prime) **spectrum** of R. We denote it, by

$$\mathrm{Spec}(R) \;:=\; \{\, \mathfrak{p} \subseteq R \mid (1), (2) \text{ and } (3) \,\}$$

An ideal $\mathfrak{p}_* \trianglelefteq_{\mathfrak{i}} R$ is said to be a **minimal prime ideal** of R, iff it is a minimal element of $\mathrm{Spec}(R)$. That is $\mathfrak{p}_* \in \mathrm{Spec}(R)$ and for any prime ideal $\mathfrak{p} \in \mathrm{Spec}(R)$ we get the implication $\mathfrak{p} \subseteq \mathfrak{p}_* \implies \mathfrak{p} = \mathfrak{p}_*$. The set of all minimal prime ideals is called the **minimal spectrum** of R, denoted by

$$\mathrm{Smin}(R) \;:=\; \Big(\mathrm{Spec}(R)\Big)_*$$

(2.12) Proposition: (viz. 879)
Let $(R,+,\cdot)$ be a commutative ring and $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$ be an ideal of R. Then the following four statements concerning $\mathfrak{p}$ are equivalent

(a) $\mathfrak{p}$ is a prime ideal

(b) the quotient ring $R/\mathfrak{p}$ is an integral domain (in particular non-zero)

(c) the complement $U := R \setminus \mathfrak{p}$ is a *multiplicatively closed* set, this is to say that

 (1) $1 \in U$
 (2) $u, v \in U \implies uv \in U$

(d) $\mathfrak{p} \neq R$ is a proper ideal and for any two ideals $\mathfrak{a}, \mathfrak{b} \trianglelefteq_{\mathfrak{i}} R$ we get the implication

$$\mathfrak{ab} \subseteq \mathfrak{p} \quad\Longrightarrow\quad \mathfrak{a} \subseteq \mathfrak{p} \text{ or } \mathfrak{b} \subseteq \mathfrak{p}$$

(2.13) Remark:
At this point we can reap an important harvest of the theory: *Maximal ideals are prime*. Using the machinery of algebra this can be seen in a most beautiful way: If $\mathfrak{m}$ is a maximal ideal, then $R/\mathfrak{m}$ is a field by (2.5). But fields are (by definition non-zero) integral domains. Hence $\mathfrak{m}$ already is prime by (2.12). Of course it is also possible to give a direct proof - one of these will be presented in (2.24).

(2.14) Proposition: (viz. 882)
Let $(R,+,\cdot)$ be a commutative ring and $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ be a prime ideal of R, then we find the following truisms

(i) If $a_1,\ldots,a_k \in R$ are finitely many elements then by induction we obtain the following implication

$$a_1 \ldots a_k \in \mathfrak{p} \implies \exists\, i \in 1 \ldots k \,:\, a_i \in \mathfrak{p}$$

(ii) Likewise let $\mathfrak{a}_1,\ldots,\mathfrak{a}_k \trianglelefteq_{\mathrm{i}} R$ be finitely many ideals of R, then by induction we also find the following implication

$$\bigcap_{i=1}^{k} \mathfrak{a}_i \subseteq \mathfrak{p} \implies \exists\, i \in 1 \ldots k \,:\, \mathfrak{a}_i \subseteq \mathfrak{p}$$

(iii) *Prime Avoidance*: Consider some ideals $\mathfrak{b}_1,\ldots,\mathfrak{b}_n \trianglelefteq_{\mathrm{i}} R$ where $2 \leq n \in \mathbb{N}$ such that $\mathfrak{b}_3,\ldots,\mathfrak{b}_n$ are prime ideals of R. If now $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is any ideal, then we obtain the following implication

$$\mathfrak{a} \subseteq \bigcup_{i=1}^{n} \mathfrak{b}_i \implies \exists\, i \in 1 \ldots n \,:\, \mathfrak{a} \subseteq \mathfrak{b}_i$$

(iv) If $R \neq 0$ is a non-zero, commutative ring, then the following three statements concerning the spectrum of R are equivalent

(a) $\mathrm{Spec}(R) = \mathrm{Smax}(R)$

(b) $\mathrm{Smin}(R) = \mathrm{Smax}(R)$

(c) $(\diamondsuit)$ $\mathrm{kdim} R = 0$

(2.15) Example:
In a less formalistic way the prime avoidance lemma can be put like this: If an ideal $\mathfrak{a}$ is contained in the union of finitely many ideals $\mathfrak{b}_i$ of which at most two are non-prime, then it already is contained in one of these. In spite of the odd assumption the statement is rather sharp. In fact it may happen that $\mathfrak{a}$ is contained in the union of three strictly smaller ideals (which of course are all non-prime in this case). Let us give an example of this: Fix the field $E := \mathbb{Z}_2$ and the ideal $\mathfrak{o} := \langle s,t\rangle_{\mathrm{i}}^2 = \langle s^2, st, t^2\rangle_{\mathrm{i}} \trianglelefteq_{\mathrm{i}} E[s,t]$. Then the ring in consideration is

$$R := E[s,t] \Big/ \mathfrak{o}$$

Note that any residue class of $f \in E[s,t]$ can be represented in the form $f + \mathfrak{o} = f[0,0] + f[1,0]s + f[0,1]t + \mathfrak{o}$. That is R contains precisely 6 elements, namely $a + bs + ct + \mathfrak{o}$ where a, b and $c \in E = \mathbb{Z}_2$. Now take the following ideal

$$\begin{aligned} \mathfrak{a} &:= \langle s+\mathfrak{o}, t+\mathfrak{o}\rangle_{\mathrm{i}} \Big/ \mathfrak{o} \\ &= \{\, f+\mathfrak{o} \mid f \in E[s,t], f[0,0] = 0 \,\} \\ &= \{\, 0+\mathfrak{o}, s+\mathfrak{o}, t+\mathfrak{o}, s+t+\mathfrak{o} \,\} \end{aligned}$$

On the other hand let us also take the ideals $\mathfrak{b}_1 := (s+\mathfrak{o})R$, $\mathfrak{b}_2 := (t+\mathfrak{o})R$ and $\mathfrak{b}_2 := (s+t+\mathfrak{o})R$. Now an easy computation (e.g. for $\mathfrak{b}_1$ we get $(s+\mathfrak{o})(a+bs+ct+\mathfrak{o}) = as+\mathfrak{o}$) yields the identities

$$\begin{aligned}\mathfrak{b}_1 &= \{\,0+\mathfrak{o}, s+\mathfrak{o}\,\}\\ \mathfrak{b}_2 &= \{\,0+\mathfrak{o}, t+\mathfrak{o}\,\}\\ \mathfrak{b}_3 &= \{\,0+\mathfrak{o}, s+t+\mathfrak{o}\,\}\end{aligned}$$

And hence it is clear that any $\mathfrak{b}_i \subset \mathfrak{a}$ is a strict subset, but the union of these ideals is precisely $\mathfrak{a}$ again

$$\mathfrak{a} = \mathfrak{b}_1 \cup \mathfrak{b}_2 \cup \mathfrak{b}_3$$

(2.16) Remark: (viz. 883)
Let $(R,+,\cdot)$ be a commutative ring again and consider some ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$. Then we denote the set of all prime ideals containing $\mathfrak{a}$ by

$$\mathbb{V}(\mathfrak{a}) := \{\,\mathfrak{p} \in \operatorname{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p}\,\}$$

If now $\mathfrak{a}_i \trianglelefteq_{\mathrm{i}} R$ is an ideal of R for any $i \in 1\ldots n$ resp. for any $i \in I$ (where $I \neq \emptyset$ is an arbitrary index set) and $a, b \in R$ are any elements of R, then we find the identities

$$\begin{aligned}\mathbb{V}(0) &= \operatorname{Spec}(R)\\ \mathbb{V}(R) &= \emptyset\\ \mathbb{V}\left(\sum_{i\in I}\mathfrak{a}_i\right) &= \bigcap_{i\in I}\mathbb{V}(\mathfrak{a}_i)\\ \mathbb{V}\left(\bigcap_{i=1}^{n}\mathfrak{a}_i\right) &= \bigcup_{i=1}^{n}\mathbb{V}(\mathfrak{a}_i)\\ \mathbb{V}\big(abR\big) &= \mathbb{V}\big(aR\big)\cup\mathbb{V}\big(bR\big)\end{aligned}$$

($\diamondsuit$) These simple properties have more impact than one might expect. Let us give a slight glimpse of the future, far far ahead of us: These properties state, that the sets $\mathbb{V}(\mathfrak{a})$ form the closed sets of a topology on the spectrum of R. This topology on $\operatorname{Spec}(R)$ is called the **Zariski topology** and it is the staging point of both, abstract algebraic geometry and number theory. Some more comments on this can be found in remark (2.32). These fields of mathematics deserve a textbook of their own however and we will not venture into these much further here. The following lemma however ensures however, that a ring homomorphism $\varphi : R \to S$ induces a continuous map $\operatorname{Spec}(\varphi)$ with respect to the Zariski-topology. So going to the spectrum is a contra-variant functor from the category of commutative rings to the category of topological spaces.

(2.17) Lemma: (viz. 884)
Let $(R,+,\cdot)$ and $(S,+,\cdot)$ be any two commutative rings and denote their prime spectra by $X := \operatorname{Spec}(R)$ and $Y := \operatorname{Spec}(S)$ respectively. Now consider some ring-homomorphism $\varphi : R \to S$. Then φ induces a well-defined map on the spectra of S and R, by virtue of

$$\operatorname{Spec}(\varphi) \;:\; Y \to X \;:\; \mathfrak{q} \mapsto \varphi^{-1}(\mathfrak{q})$$

For any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ let us denote $\mathbb{V}(\mathfrak{a}) := \{\, \mathfrak{p} \in X \mid \mathfrak{a} \subseteq \mathfrak{p} \,\}$ again and for an element $a \in R$ let us appreviate $X_a := \{\, \mathfrak{p} \in X \mid a \notin \mathfrak{p} \,\}$. If now $a \in R$, $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ and $\mathfrak{b} \trianglelefteq_{\mathrm{i}} S$, then $\mathrm{Spec}(\varphi)$ satisfies

$$\begin{aligned} (\mathrm{Spec}(\varphi))^{-1}(X_a) &= Y_{\varphi(a)} \\ (\mathrm{Spec}(\varphi))\,(\mathbb{V}(\mathfrak{b})) &\subseteq \mathbb{V}\left(\varphi^{-1}(\mathfrak{b})\right) \\ (\mathrm{Spec}(\varphi))^{-1}\,(\mathbb{V}(\mathfrak{a})) &= \mathbb{V}\left(\langle \varphi(\mathfrak{a}) \rangle_{\mathrm{i}}\right) \end{aligned}$$

(2.18) Lemma: (viz. 880)

(i) Let $(R, +, \cdot)$ be a commutative ring and $\mathcal{P} \subseteq \mathrm{Spec}(R)$ be a chain of prime ideals of R (that is $\mathcal{P} \neq \emptyset$ and for any $\mathfrak{p}, \mathfrak{q} \in \mathcal{P}$ we have $\mathfrak{p} \subseteq \mathfrak{q}$ or $\mathfrak{q} \subseteq \mathfrak{p}$). Then both, the union and the intersection of all the $\mathfrak{p} \in \mathcal{P}$ are prime ideals of R again, formally

$$\mathcal{P} \subseteq \mathrm{Spec}(R),\ \mathcal{P} \neq \emptyset \quad \text{chain} \quad \Longrightarrow \quad \bigcup \mathcal{P} \text{ and } \bigcap \mathcal{P} \trianglelefteq_{\mathrm{i}} R \quad \text{prime}$$

(ii) Let $\mathcal{P} \subseteq \mathrm{Spec}(R)$ be a non-empty ($\mathcal{P} \neq \emptyset$) set of prime ideals of the commutative ring $(R, +, \cdot)$ and assume that $\mathcal{P}$ also contains any prime ideal, that is contained in any of its members

$$\forall\, \mathfrak{p} \in \mathrm{Spec}(R)\ \ \forall\, \mathfrak{q} \in \mathcal{P}\ \ :\ \ \mathfrak{p} \subseteq \mathfrak{q} \ \Longrightarrow\ \ \mathfrak{p} \in \mathcal{P}$$

then $\mathcal{P}$ already contains a minimal element: $\mathcal{P}_* \neq \emptyset$.

(iii) Let $(R, +, \cdot)$ be a commutative ring and consider an arbitrary ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ and a prime ideal $\mathfrak{q} \trianglelefteq_{\mathrm{i}} R$. We now give a short list of possible *conditions* we may impose and the respective *assumptions* that have to be supposed for $\mathfrak{a}$ and $\mathfrak{q}$ in this case

assumption	condition($\mathfrak{p}$)
$R \neq 0$	none
nothing	$\mathfrak{p} \subseteq \mathfrak{q}$
$\mathfrak{a} \neq R$	$\mathfrak{a} \subseteq \mathfrak{p}$
$\mathfrak{a} \subseteq \mathfrak{q}$	$\mathfrak{a} \subseteq \mathfrak{p} \subseteq \mathfrak{q}$

Then there is a prime ideal $\mathfrak{p}$ of R that is minimal among all prime ideals satisfying the condition imposed. Formally put: If the respective assumption is true, then

$$\{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \text{condition}(\mathfrak{p}) \,\}_* \ \neq\ \emptyset$$

(iv) Let $(R, +, \cdot)$ be a commutative ring, $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be any ideal and $\mathfrak{q} \trianglelefteq_{\mathrm{i}} R$ a prime ideal with $\mathfrak{a} \subseteq \mathfrak{q}$. Then there is a prime ideal $\mathfrak{p}_*$ minimal over $\mathfrak{a}$ that is contained in $\mathfrak{q}$. Formally that is

$$\exists\, \mathfrak{p}_* \in \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p} \,\}_* \quad \text{with} \quad \mathfrak{a} \subseteq \mathfrak{p}_* \subseteq \mathfrak{q}$$

(v) Let $(R, +, \cdot)$ be a commutative ring, $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be an ideal of R and $U \subseteq R$ be a multiplicatively closed set (that is $1 \in U$ and $u, v \in U$ implies $uv \in U$). If now $\mathfrak{a} \cap U = \emptyset$ then the set of all ideals $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ satisfying $\mathfrak{a} \subseteq \mathfrak{b} \subseteq R \setminus U$ contains maximal elements. And any such is maximal element is a prime ideal, formally

$$\emptyset \neq \{ \mathfrak{b} \trianglelefteq_{\mathrm{i}} R \mid \mathfrak{a} \subseteq \mathfrak{b} \subseteq R \setminus U \}^* \subseteq \mathrm{Spec}(R)$$

(2.19) Corollary: (viz. 1102)

(i) Let $(R, +, \cdot)$ be a non-zero $R \neq 0$, commutative ring, then any zero-divisor of R is contained in a prime ideal that is contained in the subset of zero-divisors. In other words the set of zero-divisors of R is the union of all prime ideals of R, that are contained in the zero-divisors

$$\mathrm{zd}(R) = \bigcup \{ \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{p} \subseteq \mathrm{zd}(R) \}$$

(ii) In a commutative ring $(R, +, \cdot)$ the minimal prime ideals are already contained in the zero-divisors of R. Formally put, this is the following implication

$$\mathfrak{p} \in \mathrm{Smin}(R) \implies \mathfrak{p} \subseteq \mathrm{zd}(R)$$

(iii) Let $(R, +, \cdot)$ be a commutative ring and recall that we defined the *nil-radical* of R to be the ideal of nil-potent elements $\mathrm{nil}(R) := \{ a \in R \mid \exists n \in \mathbb{N} : a^n = 0 \}$. It is clear, that $\mathrm{nil}(R) \subseteq \mathfrak{p}$ for any prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$. And thereby we find a one-to-one correspondence between the prime ideals of the rings R and $R/\mathrm{nil}(R)$

$$\mathrm{Spec}(R) \longleftrightarrow \mathrm{Spec}\left(R \Big/ \mathrm{nil}(R) \right) \; : \; \mathfrak{p} \mapsto \mathfrak{p} \Big/ \mathrm{nil}(R)$$

2.3 Radical Ideals

(2.20) Definition:
Let $(R,+,\cdot)$ be a commutative ring, $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be an ideal and $b \in R$ be an element of R. Then we define both the **radical** $\sqrt{\mathfrak{a}}$ and **fraction** $\mathfrak{a} : b$ of $\mathfrak{a}$ to be the following sets

$$\begin{aligned} \sqrt{\mathfrak{a}} &:= \left\{ a \in R \mid \exists k \in \mathbb{N} : a^k \in \mathfrak{a} \right\} \\ \mathfrak{a} : b &:= \{ a \in R \mid ab \in \mathfrak{a} \} \end{aligned}$$

Now $\mathfrak{a}$ is said to be a **radical ideal** (sometimes this is also called *perfect ideal* in literature), iff $\mathfrak{a}$ equals its own radical, that is iff we have the properties

(1) $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$

(2) $\mathfrak{a} = \sqrt{\mathfrak{a}}$

And we define the **radical spectrum** $\mathrm{Srad}(R)$ of R to be the set of all radical ideals of R, formally that is

$$\mathrm{Srad}(R) := \left\{ \mathfrak{a} \trianglelefteq_{\mathrm{i}} R \mid \mathfrak{a} = \sqrt{\mathfrak{a}} \right\}$$

(2.21) Example:
Consider the integers $\mathbb{Z}$ and some ideal $a\mathbb{Z} \trianglelefteq_{\mathrm{i}} \mathbb{Z}$ within, where we take $a \geq 2$. If we now pick up a prime factorization of a, say $a = p_1^{k(1)} \dots p_r^{k(r)}$ with pairwise distinct prime factors $p_i \neq p_j$ (whenever $i \neq j \in 1 \dots r$), then the radical ideal of $a\mathbb{Z}$ is just

$$\sqrt{a\mathbb{Z}} = (p_1 \dots p_r)\mathbb{Z}$$

Prob Let $q = p_1 \dots p_r$ and $k = \max\{ k(1), \dots, k(r) \}$. Then it is clear that $a \mid q^k$ and hence q is contained in the radical of $a\mathbb{Z}$. Conversely consider any $b \in \sqrt{a\mathbb{Z}}$, that is $a \mid b^k$ for some $k \in \mathbb{N}$. Then for any $i \in 1 \dots r$ we have $p_i \mid a \mid b^k$ such that $p_i \mid b^k$. But as p_i is prime, this yields $p_i \mid b$, but as this is true for any p_i we conclude $q \mid b$ from this.

(2.22) Proposition: (viz. 884)
Let again $(R,+,\cdot)$ be a commutative ring, $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be an ideal and $b \in R$ be an element of R. Then we obtain the following statements

(i) The fraction $\mathfrak{a} : b$ is an ideal of R again containing $\mathfrak{a}$, that is: $\mathfrak{a} \subseteq \mathfrak{a} : b \trianglelefteq_{\mathrm{i}} R$.

(ii) The radical $\sqrt{\mathfrak{a}}$ even is a radical ideal of R containing $\mathfrak{a}$, that is: $\mathfrak{a} \subseteq \sqrt{\mathfrak{a}} \in \mathrm{Srad}(R)$.

(iii) Going to fractions resp. taking to radical ideals is monotonous, concerning the inclusion of sets. That is, if $\mathfrak{a}, \mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ are any ideals and $b \in R$, then we find

$$\begin{aligned} \mathfrak{a} \subseteq \mathfrak{b} &\implies \mathfrak{a} : b \subseteq \mathfrak{b} : b \\ \mathfrak{a} \subseteq \mathfrak{b} &\implies \sqrt{\mathfrak{a}} \subseteq \sqrt{\mathfrak{b}} \end{aligned}$$

(iv) The fraction ideal $\mathfrak{a} : b$ is proper if and only if $b \notin \mathfrak{a}$, that is we find the equivalence of

$$\mathfrak{a} : b \;=\; R \quad\Longleftrightarrow\quad b \;\in\; \mathfrak{a}$$

In particular, if $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ even is a prime ideal then we are left with precisely two cases

$$\mathfrak{p} : b \;=\; \begin{cases} R \text{ if } b \in \mathfrak{p} \\ \mathfrak{p} \text{ if } b \notin \mathfrak{p} \end{cases}$$

(v) The intersection of a non-empty collection $\mathcal{A} \subseteq \operatorname{Srad}(R)$ of radical ideals is a radical ideal again

$$\mathcal{A} \subseteq \operatorname{Srad}(R),\ \mathcal{A} \neq \emptyset \quad\Longrightarrow\quad \bigcap \mathcal{A} \in \operatorname{Srad}(R)$$

(vi) Let $\mathfrak{a}_i \trianglelefteq_{\mathrm{i}} R$ be an arbitrary family of ideals ($i \in I \neq \emptyset$) and $b \in R$. Then we find the identity of

$$\bigcap_{i \in I} (\mathfrak{a}_i : b) \;=\; \left(\bigcap_{i \in I} \mathfrak{a}_i \right) : b$$

(2.23) Proposition: (viz. 885)
Let $(R, +, \cdot)$ be a commutative ring and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be an ideal of R. Then the following four statements concerning $\mathfrak{a}$ are equivalent

(a) $\sqrt{\mathfrak{a}} \subseteq \mathfrak{a}$

(b) $\mathfrak{a} = \sqrt{\mathfrak{a}}$ is a radical ideal

(c) $\forall\, a \in R$ we get $\exists\, k \in \mathbb{N} : a^k \in \mathfrak{a} \implies a \in \mathfrak{a}$

(d) the quotient ring $R/\mathfrak{a}$ is *reduced*, i.e. it contains no non-zero nilpotents

$$\operatorname{NIL}\left(R \Big/ \mathfrak{a} \right) \;=\; \{\, 0 + \mathfrak{a} \,\}$$

(2.24) Corollary: (viz. 886)
Let $(R, +, \cdot)$ be a commutative ring and $\mathfrak{m}$, $\mathfrak{p}$ and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be ideals of R respectively. Then we have gained the following table of equivalences

$$\begin{aligned} \mathfrak{m} \text{ maximal} &\iff R \Big/ \mathfrak{m} \text{ field} \\ \mathfrak{p} \text{ prime} &\iff R \Big/ \mathfrak{p} \text{ integral domain} \\ \mathfrak{a} \text{ radical} &\iff R \Big/ \mathfrak{a} \text{ reduced} \end{aligned}$$

where a ring S is said to be *reduced*, iff $s^k = 0$ (for some $s \in S$ and $k \in \mathbb{N}$) implies $s = 0$. And subsuming the properties of the respective quotient rings, we thereby find the inclusions

$$\operatorname{Smax}(R) \;\subseteq\; \operatorname{Spec}(R) \;\subseteq\; \operatorname{Srad}(R)$$

(2.25) Proposition: (viz. 886)
Let $(R,+,\cdot)$ be a commutative ring once more and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be an arbitrary ideal of R. Then we obtain the following additional properties:

(i) If $\mathfrak{a}$ is proper, then the radical of $\mathfrak{a}$ is the intersection of all prime ideals containing $\mathfrak{a}$. And of course this is just the same, as taking the intersection of all prime ideals minimal over $\mathfrak{a}$:

$$\begin{aligned}\sqrt{\mathfrak{a}} &= \bigcap \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p} \,\} \\ &= \bigcap \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p} \,\}_*\end{aligned}$$

(ii) In particular the nil-radical of R is just the intersection of all (minimal) prime ideals of R, formally

$$\mathrm{NIL}(R) = \sqrt{0} = \bigcap \mathrm{Spec}(R) = \bigcap \mathrm{Smin}(R)$$

(iii) The map $\mathfrak{a} \mapsto \sqrt{\mathfrak{a}}$ is a projection on the set of ideals of R (i.e. it is idempotent). To be explicit: For any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ we find the following equality

$$\sqrt{\sqrt{\mathfrak{a}}} = \sqrt{\mathfrak{a}}$$

(iv) Given an arbitrary ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ and a prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ then for any $k \in \mathbb{N}$ we get the implication

$$\mathfrak{a}^k \subseteq \mathfrak{p} \subseteq \sqrt{\mathfrak{a}} \implies \mathfrak{p} = \sqrt{\mathfrak{a}}$$

(v) If $\mathfrak{a}$ and $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ are any two ideals of R, then the radical of the product $\mathfrak{ab}$ equals the radical of the intersection $\mathfrak{a} \cap \mathfrak{a}$, which is the intersections of the radicals again:

$$\sqrt{\mathfrak{a}\,\mathfrak{b}} = \sqrt{\mathfrak{a} \cap \mathfrak{b}} = \sqrt{\mathfrak{a}} \cap \sqrt{\mathfrak{b}}$$

(vi) And thereby, for any $1 \leq n \in \mathbb{N}$ we find that the radical of the power $\mathfrak{a}^n$ is just the radical of $\mathfrak{a}$:

$$\sqrt{\mathfrak{a}^n} = \sqrt{\mathfrak{a}}$$

In particular: If $\mathfrak{a} \in \mathrm{Srad}(R)$ is a radical ideal already and $1 \leq n \in \mathbb{N}$, again then the radical of any power $\mathfrak{a}^n$ is just $\mathfrak{a}$ again. Formally this reads, as

$$\sqrt{\mathfrak{a}^n} = \mathfrak{a}$$

(vii) Let $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be a finitely generated ideal in the commutative ring $(R,+,\cdot)$. And let $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ be any another ideal of R. Then we get the implication

$$\mathfrak{a} \subseteq \sqrt{\mathfrak{b}} \implies \exists\, k \in \mathbb{N} \,:\, \mathfrak{a}^k \subseteq \mathfrak{b}$$

(viii) Consider an arbitrary family of ideals $\mathfrak{a}_i \trianglelefteq_{\mathrm{i}} R$ (where $i \in I$ and $I \neq \emptyset$ is any non-empty set of indices), then we obtain the following two inclusions

$$\begin{aligned} \sum_{i\in I} \sqrt{\mathfrak{a}} &\subseteq \sqrt{\sum_{i\in I} \mathfrak{a}_i} \\ \sqrt{\bigcap_{i\in I} \mathfrak{a}_i} &\subseteq \bigcap_{i\in I} \sqrt{\mathfrak{a}_i} \end{aligned}$$

(2.26) Remark:
Due to (2.22.(v)) the intersection of radical ideals yields a radical ideal. And in (2.24) we have just seen that maximal and prime ideals already are radical. Now recall that the *jacobson-radical* $\textsc{jac}(R)$ has been defined to be the intersection of all maximal ideals. And we have just seen in (2.25.(ii)) above that the *nil-radical* is the intersection of all (minimal) prime ideals. This means that both are radical ideals (and hence the word *radical* in their names)

$$\begin{aligned} \textsc{jac}(R) &= \bigcap \mathrm{Smax}(R) \in \mathrm{Srad}(R) \\ \textsc{nil}(R) &= \bigcap \mathrm{Spec}(R) \in \mathrm{Srad}(R) \end{aligned}$$

(2.27) Example:
Note however, that taking sums and radicals of (even finitely many) ideals do *not* commute. That is there is *no* analogous statement to (2.25.(v)) concerning sums $\mathfrak{a} + \mathfrak{b}$. As an example consider $R := E[s,t]$, the polynomial ring in two variables, where $(E, +, \cdot)$ is an arbitrary field. Now pick up

$$\mathfrak{p} := (s^2 - t)R \quad \text{and} \quad \mathfrak{q} := tR$$

It is clear that $\mathfrak{p}$ and $\mathfrak{q}$ are prime ideals (as the quotient is isomorphic to the integral domain $E[s]$ under the isomorphisms induced by $f(s,t) \mapsto f(s,s^2)$ and $f(s,t) \mapsto f(s,0)$ respectively). However the sum $\mathfrak{p} + \mathfrak{q}$ of both not even is a radical ideal, in fact we get

$$\mathfrak{p} + \mathfrak{q} = s^2R + tR \subset sR + tR = \sqrt{\mathfrak{p} + \mathfrak{q}}$$

Prob We first prove $\mathfrak{p} + \mathfrak{q} = s^2R + tR$ - thus consider any $h = (s^2 - t)f + tg \in \mathfrak{p} + \mathfrak{q}$, then h can be rewritten as $h = s^2f + t(g - f) \in s^2R + tR$. But conversely $t \in \mathfrak{q} \subseteq \mathfrak{p} + \mathfrak{q}$ and $s^2 = (s^2 - t) + t \in \mathfrak{p} + \mathfrak{q}$. In particular s is contained in the radical of $\mathfrak{p} + \mathfrak{q}$ and hence $\mathfrak{p} + \mathfrak{q} \subseteq sR + tR \subseteq \sqrt{\mathfrak{p} + \mathfrak{q}}$. As $sR + tR$ is prime (even maximal) this implies the equality of the radical ideal. So finally we wish to prove $s \notin \mathfrak{p} + \mathfrak{q}$ (and in particlar $\mathfrak{p} + \mathfrak{q}$ is no radical ideal. Thus suppose $s = s^2f + tg$ for some polynomials $f, g \in R$. Then (as s is prime and does not divide t) s divides g. To be precise we get $g = sh$ for $h = (1 - st)/t \in R$. And hence we get $s = s^2f + sth$. Eliminating s we find $1 = sf + th$, an equation that cannot hold true (as 1 is of degree 0 and $sf + th$ of degree at least 1). Thus we got $s^2 \notin s^2R + tR$.

(2.28) Example: (viz. 888)
Be aware that radicals may be very large when compared with their original ideals. E.g. it may happen that $\mathfrak{a} = aR$ is a principal ideal, but $\sqrt{\mathfrak{a}}$ is *not* finitely generated. In fact in the chapter of proofs we give an example where there even is no $n \in \mathbb{N}$ such that $(\sqrt{\mathfrak{a}})^n \subseteq \mathfrak{a}$, as well.

(2.29) Remark:
Combining (2.22.(iii)) and (viii) in the above proposition it is clear that for an arbitrary collection of ideals $\mathfrak{a}_i \trianglelefteq_{\mathrm{i}} R$ (where $i \in I$) in a commutative ring $(R, +, \cdot)$ we obtain the following equalities

$$\begin{aligned} \sqrt{\sum_{i\in I} \sqrt{\mathfrak{a}}} &= \sqrt{\sum_{i\in I} \mathfrak{a}_i} \\ \sqrt{\bigcap_{i\in I} \sqrt{\mathfrak{a}_i}} &= \sqrt{\bigcap_{i\in I} \mathfrak{a}_i} \end{aligned}$$

(2.30) Example:
The inclusions in (2.25.(viii)) need *not* be equalities! As an example let us consider the ring of integers $R = \mathbb{Z}$. And let us take $I = \mathbb{N}$ and $\mathfrak{a}_i = p^i\mathbb{Z}$ for some prime number $p \in \mathbb{Z}$. As any non-zero element of $\mathbb{Z}$ is divisible by finite powers p^i only the intersection of the $\mathfrak{a}_i$ is $\{0\}$. On the other hand $\sqrt{\mathfrak{a}_i} = p\mathbb{Z}$ due to (2.25.(vii)) and since $p\mathbb{Z}$ is a prime (and hence radical) ideal of $\mathbb{Z}$. Thereby we found the counterexample

$$\sqrt{\bigcap_{i\in\mathbb{N}} \mathfrak{a}_i} = \sqrt{0} = 0 \subset p\mathbb{Z} = \bigcap_{i\in\mathbb{N}} p\mathbb{Z} = \bigcap_{i\in\mathbb{N}} \sqrt{\mathfrak{a}_i}$$

(2.31) Proposition: (viz. 889)
Let now $\varphi : R \to S$ be a ring-homomorphism between the commutative rings $(R, +, \cdot)$ and $(S, +, \cdot)$. And consider the ideals $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ and $\mathfrak{b} \trianglelefteq_{\mathrm{i}} S$. Then let us denote the transferred ideals of $\mathfrak{a}$ and $\mathfrak{b}$

$$\begin{aligned} \mathfrak{b} \cap R &:= \varphi^{-1}(\mathfrak{b}) \trianglelefteq_{\mathrm{i}} R \\ \mathfrak{a}S &:= \langle \varphi(\mathfrak{a}) \rangle_{\mathrm{i}} \trianglelefteq_{\mathrm{i}} S \end{aligned}$$

Note that in case that φ is surjective (but in generall), we get $\mathfrak{a}S = \varphi(\mathfrak{a})$. Now, using these notions, we obtain the following four statements

(i) Pulling back ideals commutes with taking radical ideals, that is the radical of the pull-back of $\mathfrak{b}$ is just the pull-back of the radical of $\mathfrak{b}$

$$\sqrt{\mathfrak{b} \cap R} = \sqrt{\mathfrak{b}} \cap R$$

(ii) This is not true for the push-out of ideals, here we only find: The push-out of the radical ideal of $\mathfrak{a}$ is contained in the radical of the push-out of $\mathfrak{a}$

$$\sqrt{\mathfrak{a}}S \subseteq \sqrt{\mathfrak{a}S} = \sqrt{\sqrt{\mathfrak{a}}S}$$

(iii) Now let us abbreviate by $\star$ any of the properties *maximal ideal*, *prime ideal* or *radical ideal*. Then we find the equivalences

$$\mathfrak{b} \text{ is a } \star \iff \mathfrak{b} \cap R \text{ is a } \star$$

And if $\varphi : R \twoheadrightarrow S$ even is a surjective homomorphism, then we obtain another set of equivalences of

$$\mathfrak{a} + \ker(\varphi) \text{ is a } \star \iff \mathfrak{a}S \text{ is a } \star$$

(2.32) Remark:
Let $(R, +, \cdot)$ be a commutative ring and let us introduce the following maps on the set of ideals of R, respectively on the set of subsets of the spectrum of R

$$\mathbb{V} : \operatorname{Ideal}(R) \to \mathcal{P}\big(\operatorname{Spec}(R)\big) : \mathfrak{a} \mapsto \{\, \mathfrak{p} \in \operatorname{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p} \,\}$$
$$\mathbb{I} : \mathcal{P}\big(\operatorname{Spec}(R)\big) \to \operatorname{Ideal}(R) : \mathcal{X} \mapsto \begin{cases} \bigcap \mathcal{X} \text{ if } \mathcal{X} \neq \emptyset \\ R \text{ if } \mathcal{X} = \emptyset \end{cases}$$

Clearly these sets are partially ordered under inclusion, that is $(\operatorname{Ideal}(R), \subseteq)$ and $(\mathcal{P}(\operatorname{Spec}(R)), \subseteq)$ are partially ordered sets. Also it is clear that $\mathbb{V}$ and $\mathbb{I}$ are anti-tonous (aka order-reversing), that is for any $\mathfrak{a}, \mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ and any $\mathcal{X}, \mathcal{Y} \subseteq \operatorname{Spec}(R)$ we find that

$$\mathfrak{a} \subseteq \mathfrak{b} \implies \mathbb{V}(\mathfrak{b}) \subseteq \mathbb{V}(\mathfrak{a})$$
$$\mathcal{X} \subseteq \mathcal{Y} \implies \mathbb{I}(\mathcal{Y}) \subseteq \mathbb{I}(\mathcal{X})$$

Recall the notion of a Galois connection introduced in (0.22). In (2.25.(i)) we have seen that $(\mathbb{V}, \mathbb{I})$ is a Galois connection between $(\operatorname{Ideal}(R), \subseteq)$ and $(\mathcal{P}(\operatorname{Spec}(R)), \subseteq)$, as these maps satisfy

$$\mathfrak{a} \subseteq \sqrt{\mathfrak{a}} = \mathbb{I}\mathbb{V}(\mathfrak{a})$$
$$\mathcal{X} \subseteq \mathbb{V}\mathbb{I}(\mathcal{X})$$

[the latter property being trivial, as $\bigcap \mathcal{X} \subseteq \mathfrak{p}$ for any $\mathfrak{p} \in \mathcal{X}$]. As with any Galois connection $\mathbb{V}$ and $\mathbb{I}$ now provide a one-to-one correspondence between their respective images, in this case these are

$$\operatorname{Srad}(R) = \operatorname{im}(\mathbb{I})$$
$$\mathcal{Z}_R := \operatorname{im}(\mathbb{V})$$

Thereby $\mathcal{Z}_R$ contains $\mathbb{V}(0) = \operatorname{Spec}(R)$ and $\mathbb{V}(R) = \emptyset$ and is closed under finite unions and arbitrary intersections, as we have seen in (2.16). In section 8.8 we will use these properties to introduce the so-called the *Zariski topology* on $\operatorname{Spec}(R)$ by taking $\mathcal{T}_R := \{\, \complement\mathbb{V}(\mathfrak{a}) \mid \mathfrak{a} \trianglelefteq_{\mathrm{i}} R \,\}$ to be the collection of open sets on $\operatorname{Spec}(R)$. This is possible, since we have

$$\mathbb{V}\left(\sum_{i \in I} \mathfrak{a}_i\right) = \bigcap_{i \in I} \mathbb{V}(\mathfrak{a}_i)$$
$$\mathbb{V}\left(\bigcap_{i=1}^{n} \mathfrak{a}_i\right) = \bigcup_{i=1}^{n} \mathbb{V}(\mathfrak{a}_i)$$

Jacobson Rings

The Jacobson property is an elementary notion and while it looks innocuous, it in fact is a rather strong assumption, that few rings satisfy. The integers $\mathbb{Z}$ and any field is a Jacobson ring. However this notion has excellent hereditary properties – it transfers to polynomial rings and epimorphic images and hence to finitely generated algebras (2.172). We will find that Hilbert rings are an equivalent notion in section 2.13, that are of special interest in polynomial rings. But we are getting ahead of ourselves – let us start with a definition that already contains several conditions, that all are equivalent:

(2.33) Definition: (viz. 890)

Let $(R,+,\cdot)$ be a commutative ring, then the following six properties for R are equivalent. And if R satisfies one (and hence all) of them, R is said to be a **Jacobson ring** or simply to be **jacobson**.

(a) The radical of any proper ideal is the intersection of maximal ideals of R. That is: For any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ with $\mathfrak{a} \neq R$ there is a non-empty set $\mathcal{M} \subseteq \operatorname{Smax}(R)$, such that

$$\sqrt{\mathfrak{a}} \;=\; \bigcap \mathcal{M}$$

(b) The radical of any proper ideal is the intersection of the maximal ideals of R containing it. That is: For any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ with $\mathfrak{a} \neq R$ we get the identity

$$\sqrt{\mathfrak{a}} \;=\; \bigcap \{\, \mathfrak{m} \in \operatorname{Smax}(R) \mid \mathfrak{a} \subseteq \mathfrak{m} \,\}$$

(c) Any prime ideal is the intersection of the maximal ideals of R containing it. That is: For any prime ideal $\mathfrak{p} \in \operatorname{Spec}(R)$ we get the identity

$$\mathfrak{p} \;=\; \bigcap \{\, \mathfrak{m} \in \operatorname{Smax}(R) \mid \mathfrak{p} \subseteq \mathfrak{m} \,\}$$

(d) For any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ the Jacobson-radical and nil-radical of the quotient ring $R/\mathfrak{a}$ coincide, i.e.

$$\operatorname{JAC}\left(R \big/ \mathfrak{a}\right) \;=\; \operatorname{NIL}\left(R \big/ \mathfrak{a}\right)$$

(e) For any prime ideal $\mathfrak{p} \in \operatorname{Spec}(R)$ the Jacobson-radical of the quotient ring $R/\mathfrak{p}$ vanishes, that is

$$\operatorname{JAC}\left(R \big/ \mathfrak{p}\right) \;=\; 0$$

(f) If $(S,+,\cdot)$ is an integral domain and $\varphi : R \twoheadrightarrow S$ is a surjective homomorphism of rings, then the Jacobson-radical of S vanishes, formally

$$\operatorname{JAC}(S) \;=\; 0$$

Nota By (2.25.(i)) the radical $\sqrt{\mathfrak{a}}$ of an ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is the intersection of all *prime* ideals containing $\mathfrak{a}$. Now property (b) tells us, that the defining property of a Jacobson ring is, that this is the same as the intersection of all *maximal* ideals containing $\mathfrak{a}$. This is a strong restriction.

2.4 Noetherian Rings

In this section we will introduce and study noetherian and artinian rings. Both types of rings are defined by a chain condition on ideals - ascending in the case of noetherian and descending in the case of artinian rings. So one might expect a completely dual theory for these two objects. Yet this is not the case! In fact it turns out that the artinian property is much stronger: Any artinian ring already is noetherian, but the converse is false. And while examples of noetherian rings are abundant, there are few artinian rings. On the other hand both kinds of rings have several similar properties, e.g. both are very well-behaved under taking quotients or localizations.
Throughout the course of this book we will see that noetherian rings have lots of beautiful properties. E.g. they allow the Lasker-Noether decomopsition of ideals. However in non-noetherian rings peculiar things may happen. Together with the easy properties of inheritance this makes noetherian rings one of the predominant objects of commutative algebra and algebraic geometry. Artinian rings are of lesser importance, yet they arise naturally in number theory and the theory of algebraic curves.

(2.34) Definition: (viz. 1031)
Let $(R,+,\cdot)$ be a commutative ring, then R is said to be **noetherian** iff it satisfies one of the following five equivalent conditions

(a) R satisfies the *ascending chain condition* (ACC) of ideals - that is any family of ideals $\mathfrak{a}_k \trianglelefteq_{\mathfrak{i}} R$ of R (where $k \in \mathbb{N}$) that forms an ascending chain of ideals

$$\mathfrak{a}_0 \subseteq \mathfrak{a}_1 \subseteq \ldots \subseteq \mathfrak{a}_k \subseteq \mathfrak{a}_{k+1} \subseteq \ldots$$

becomes eventually constant - that is there is some $s \in \mathbb{N}$, such that the chain actually looks like

$$\mathfrak{a}_0 \subseteq \mathfrak{a}_1 \subseteq \ldots \subseteq \mathfrak{a}_s = \mathfrak{a}_{s+1} = \ldots$$

(b) Every non-empty family of ideals contains a maximal element, that is: Given $\mathcal{A} \subseteq \mathrm{Ideal}(R)$ such that $\mathcal{A} \neq \emptyset$ there is some $\mathfrak{a}^* \in \mathcal{A}^*$ (i.e $\forall\, \mathfrak{a} \in \mathcal{A}$ we get $\mathfrak{a}^* \subseteq \mathfrak{a} \implies \mathfrak{a}^* = \mathfrak{a}$).

(c) If $(\mathfrak{a}_i) \subseteq \mathrm{Ideal}(R)$ is an arbitrary collection (i.e. $i \in I$ for an arbitrary set $I \neq \emptyset$) of ideals of R, then there is a finite subset $\Omega \subseteq I$ such that

$$\sum_{i \in I} \mathfrak{a}_i = \sum_{i \in \Omega} \mathfrak{a}_i$$

(d) Every ideal of R is finitely generated, formally that is: For any ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ there are some $a_1, \ldots, a_k \in R$ such that we get

$$\mathfrak{a} = \langle a_1, \ldots, a_k \rangle_{\mathfrak{i}} = a_1 R + \cdots + a_k R$$

(e) Every prime ideal of R is finitely generated, formally that is: For any prime ideal $\mathfrak{p} \in \mathrm{Spec}(R)$ there are some $a_1, \ldots, a_k \in R$ such that

$$\mathfrak{p} = \langle a_1, \ldots, a_k \rangle_{\mathfrak{i}} = a_1 R + \cdots + a_k R$$

Note that the equivalence of (a) and (b) is true for any partially ordered set $(X, \leq)$, due to (0.25). So this is just the special case of the set of ideals partially ordered under inclusion $(\mathrm{Ideal}(R), \subseteq)$. Properties (c) and (d) are a specialty of ideals in rings however. ACC gives rise to method of proving statements that is similar to induction:

(2.35) Remark: Noetherian Induction:
Let $(R, +, \cdot)$ be noetherian ring and P be a predicate on the set of ideals of R - i.e. $P(\mathfrak{a})$ either is *true* or *false*. Consider an arbitrary collection $\mathcal{A} \subseteq \mathrm{Ideal}(R)$ of ideals of R. In order to prove that P holds true for all $\mathfrak{a} \in \mathcal{A}$, it suffices to prove the following

$$\forall\, \mathfrak{a} \in \mathcal{A} \,:\, \neg P(\mathfrak{a}) \implies \exists\, \mathfrak{b} \in \mathcal{A} \,:\, \mathfrak{a} \subset \mathfrak{b} \text{ and } \neg P(\mathfrak{b})$$

Prob if there was some $\mathfrak{a}_0 \in \mathcal{A}$ such that $P(\mathfrak{a}_0)$ was false, then there was some $\mathfrak{a}_1 := \mathfrak{b} \in \mathcal{A}$ such that $\mathfrak{a}_0 \subset \mathfrak{a}_1$ and $P(\mathfrak{a}_1)$ is false again. Then we find $\mathfrak{a}_2 := \mathfrak{b}$ with $\mathfrak{a}_1 \subset \mathfrak{a}_2$ and $\neg P(\mathfrak{a}_2)$. Continuing this way, we would end up with a strictly increasing chain $\mathfrak{a}_0 \subset \mathfrak{a}_1 \subset \mathfrak{a}_2 \subset \ldots$ of ideals, contradicting ACC.

(2.36) Example: $(\diamondsuit)$
A word of warning for the reader, who has some previous knowledge of algebraic geometry: If R is a noetherian ring, then $X := \mathrm{Spec}(R)$ is a noetherian topological space. The converse need *not* be true however. If X is a noetherian topological space, then R has to satisfy ACC for all radical ideals only. This however does not imply ACC for *all* ideals however, which is (a).

Let us present a counterexample: A ring R that satifies ACC for radical ideals (i.e. for ideals $\mathfrak{u} \trianglelefteq_{\mathfrak{i}} R$ with $\sqrt{\mathfrak{u}} = \mathfrak{u}$) but not for all ideals. We head out with any field F and take $A := F[t_0, t_1, \ldots]$ the polynomial ring in countably many variables. Now pick up the ideal of A generated by

$$\mathfrak{a} \;:=\; \langle t_k^2 - t_{k-1} \mid 1 \leq k \in \mathbb{N} \rangle_{\mathfrak{i}}$$

The evil ring is the quotient $R := A/\mathfrak{a}$. Let us abbreviate $x_k := t_k + \mathfrak{a}$, then by construction we have $x_k^2 = t_k^2 + \mathfrak{a} = t_{k-1} + \mathfrak{a} = x_{k-1}$. That is x_k is the square root of x_{k-1}. In particular $x_{k-1}R \subset x_kR$ and thereby R is not noetherian, as

$$x_0R \;\subset\; x_1R \;\subset\; x_2R \;\subset\; \ldots$$

However any $f + \mathfrak{a} \in R$ only has finitely many variables $f(t_0, \ldots, t_n)$ so $f + \mathfrak{a} = f(x_0, x_1, \ldots, x_n) \in R$. Also it has finitely many summands only. From this we see (using the polynomial rule) that $(f + \mathfrak{a})^{2n} \in F[x_0] \subseteq R$, that is for any $v = f + \mathfrak{a} \in R$ there is some $m \in \mathbb{N}$ such that $v^m \in F[x_0]$. Now consider any ascending chain of radical ideals $\sqrt{\mathfrak{u}_k} = \mathfrak{u}_k$:

$$\mathfrak{u}_0 \;\subseteq\; \mathfrak{u}_1 \;\subseteq\; \mathfrak{u}_2 \;\subseteq\; \ldots$$

This chain induces an ascending chain of ideals in $F[x_0]$, by taking $\mathfrak{a}_k := \mathfrak{u}_k \cap F[x_0] \trianglelefteq_{\mathfrak{i}} F[x_0]$. Note that $\mathfrak{a}_{k-1} = \mathfrak{a}_k$ implies $\mathfrak{u}_{k-1} = \mathfrak{u}_k$, as: Choose any $v \in \mathfrak{u}_k$ then there is some $m \in \mathbb{N}$ such that $v^m \in F[x_0]$ and hence $v^m \in \mathfrak{u}_k \cap F[x_0] = \mathfrak{a}_k = \mathfrak{a}_{k-1} = \mathfrak{u}_{k-1} \cap F[x_0]$. But $v^m \in \mathfrak{u}_{k-1}$ means $v \in \sqrt{\mathfrak{u}_{k-1}} = \mathfrak{u}_{k-1}$ such that we have $\mathfrak{u}_k \subseteq \mathfrak{u}_{k-1}$, too.

Yet $F[x_0]$ is a noetherian ring, such that the chain $\mathfrak{a}_0 \subseteq \mathfrak{a}_1 \subseteq \mathfrak{a}_2 \subseteq \ldots$ stabilizes. But as we have just argued, this implies, that the original chain $\mathfrak{u}_0 \subseteq \mathfrak{u}_1 \subseteq \mathfrak{u}_2 \subseteq \ldots$ has to stabilize, as well. Thus R satisfies ACC for all chains of radical ideals, even though it is not a noetherian ring.

The dual property DCC of ACC on ideals gives rise to another interesting notion: Commutative rings satisfying DCC on ideals will be called *artinian*. And again we find an even longer list of equivalent statements. The similarity in the definition gives strong reason to study these objects simultaneously. But as often only one half of the equivalences can be proved straightforwardly while the other half requires heavy-duty machinery that is not yet available. For a novice reader it might hence be wise to concentrate on noetherian rings only, for now. These will be the important objects later on.

(2.37) Definition: (viz. 908)
Let $(R, +, \cdot)$ be a commutative ring, then R is said to be **artinian** iff it satisfies one of the following six equivalent conditions

(a) R satisfies the *descending chain condition* (DCC) of ideals - that is any family of ideals $\mathfrak{a}_k \trianglelefteq_{\mathfrak{i}} R$ of R (where $k \in \mathbb{N}$) that forms a descending chain of ideals

$$\mathfrak{a}_0 \supseteq \mathfrak{a}_1 \supseteq \ldots \supseteq \mathfrak{a}_k \supseteq \mathfrak{a}_{k+1} \supseteq \ldots$$

becomes eventually constant - that is there is some $s \in \mathbb{N}$ such that the chain actually looks like

$$\mathfrak{a}_0 \supseteq \mathfrak{a}_1 \supseteq \ldots \supseteq \mathfrak{a}_s = \mathfrak{a}_{s+1} = \ldots$$

(b) Every non-empty family of ideals contains a minimal element, that is: Given $\mathcal{A} \subseteq \mathrm{Ideal}(R)$ such that $\mathcal{A} \neq \emptyset$ there is some $\mathfrak{a}_* \in \mathcal{A}_*$ (i.e $\forall\, \mathfrak{a} \in \mathcal{A}$ we get $\mathfrak{a} \subseteq \mathfrak{a}_* \implies \mathfrak{a} = \mathfrak{a}_*$).

(c) If $\mathcal{A} \subseteq \mathrm{Ideal}(R)$ is a family of ideals, that is totally ordered under inclusion $\subseteq$ of sets (i.e for any $\mathfrak{a}, \mathfrak{b} \in \mathcal{A}$ we have $\mathfrak{a} \subseteq \mathfrak{b}$ or $\mathfrak{b} \subseteq \mathfrak{a}$), then $\mathcal{A}$ has to be finite.

(d) R is of finite length as an R-module - that is there is an upper bound on the maximal length of a strictly ascending chain of ideals, formally

$$\ell(R) := \sup \left\{ k \in \mathbb{N} \;\middle|\; \begin{array}{l} \exists\, \mathfrak{a}_0, \mathfrak{a}_1, \ldots, \mathfrak{a}_k \trianglelefteq_{\mathfrak{i}} R : \\ \mathfrak{a}_0 \subset \mathfrak{a}_1 \subset \ldots \subset \mathfrak{a}_k \end{array} \right\} < \infty$$

(e) R is a noetherian ring in which any prime ideal already is maximal, in terms of the spectra of R:

$$\mathrm{Smax}(R) = \mathrm{Spec}(R)$$

(f) R is a noetherian ring, whose Jacobson radical equals its nil-radical [i.e. $\textsc{jac}(R) = \textsc{nil}(R)$] and that is semi-local [i.e. $\#\mathrm{Smax}(R) < \infty$].

(2.38) Remark:
So what does the noetherian resp. the artinian property mean? This can best be seen by considering a chain of principal ideals $\mathfrak{a}_k = a_k R$ of some commutative ring R. For these an ascending chain

$$\mathfrak{a}_0 \subseteq \mathfrak{a}_1 \subseteq \ldots \subseteq \mathfrak{a}_k \subseteq \mathfrak{a}_{k+1} \subseteq \ldots \subseteq R$$

is nothing but the chain of divisibilities of the elements $a_1 \mid a_0$, $a_2 \mid a_1$ and so on, such that altogether we have $\ldots\ a_{k+1} \mid a_k \mid \ldots \mid a_2 \mid a_1 \mid a_0$. It is well known, that e.g. for the integers $R = \mathbb{Z}$ any number $a = a_0 \in R$ only has finitely many divisors. Hence the chain of divisibilities has to stabilize $\ldots = a_{s+1} = a_s \mid \ldots \mid a_2 \mid a_1 \mid a_0$ at some index $s \in \mathbb{N}$. And this is precisely what the noetherian property needs:

$$\mathfrak{a}_0 \subseteq \mathfrak{a}_1 \subseteq \ldots \subseteq \mathfrak{a}_s = \mathfrak{a}_{s+1} = \ldots$$

In other words the integers $\mathbb{Z}$ are an example of a noetherian ring, since the only ideals of $\mathbb{Z}$ are principal ideals. It is worth to note, that there are rings that actually contain elements with ininitely many divisors, e.g. the ring $\mathbb{R}\{x\}$ of analytic functions over $\mathbb{R}$ allows the decomposition

$$\sin(x) = x \cdot \prod_{k=1}^{\infty} \left(1 - \frac{x^2}{k^2\pi^2}\right)$$

found by Leonhard Euler. In particular $\mathbb{R}\{x\}$ cannot be a noetherian ring. Likewise a descending chain of principal ideals $\mathfrak{a}_k = a_k R$

$$\mathfrak{a}_0 \supseteq \mathfrak{a}_1 \supseteq \ldots \supseteq \mathfrak{a}_k \subseteq \mathfrak{a}_{k+1} \supseteq \ldots \subseteq R$$

turns into an ascending chain of divivibilities $a_0 \mid a_1 \mid a_2 \mid \ldots \mid a_k \mid a_{k+1} \mid \ldots$. This is something which is easily possible in the integers, polynomials and most other rings - just keep multiplying non-unit elements. The numbers a_k will get larger, but there is no upper bound.

In case of an artinian ring however, this chain has to stabilize which means that there is some $s \in \mathbb{N}$ such that $a_s R = a_{s+1} R = \ldots$. In particular for $a_k := a^k$ for some fixed $a \in R$ we have $a^s \in a^s R = a^{s+1} R$. Thus there has to be some $u \in R$ such that $a^s = a^{s+1} u$ or in other words $a^{s+1}(au - 1) = 0$. If a is a non-zero-divisor, so is a^s such that in this case we would have $au = 1$. For this reason in an artinian ring R any non-zero-divisor already is a unit

$$R \text{ artinian} \quad \Longrightarrow \quad \text{NZD}(R) = R^*$$

From this it is clear that being an artinian ring already is a really strong property. And it is also clear, that it is hard to find examples of artinian rings that are not fields or finite rings. The artinian property lies in the zero-divisors of the ring. In consequence artinian rings not only are far less common but they also are severely more difficult to handle than noetherian rings.

(2.39) Example:

- Any field E is an noetherian and artinian ring, as it only contains the trivial ideals 0 and E. In particular the only chain of ideals with strict inclusions is $0 \subset E$ and this is finite.

- Any finite ring - such as $\mathbb{Z}_n$ - is artinian and noetherian, as it only contains finitely many ideals (and in particular any infinity chain of ideals has to be eventually constant).

- We will study principal ideal domains (PIDs) in section 2.7. These are integral domains R in which every ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ is generated by some element $a \in R$ (that is $\mathfrak{a} = aR$). In particular any ideal is finitely generated and hence any PID is noetherian.

- The integers $\mathbb{Z}$ form an easy example of a noetherian ring (as they are a PID). But they are not artinian, e.g. they contain the infinitely decreasing chain of ideals generated by powers of 2: $\mathbb{Z} \supset 2\mathbb{Z} \supset 4\mathbb{Z} \supset 8\mathbb{Z} \supset \ldots \supset 2^k\mathbb{Z} \supset \ldots$

- We will soon see (a special case of the Hilbert basis theorem) that the polynomial ring $R = E[t_1, \ldots, t_n]$ in finitely many variables over a field E is a noetherian ring. And again this is no artinian ring, as it contains the infinitely decreasing chain of ideals $R \supset t_1 R \supset t_1^2 R \supset \ldots$

- Of course there are examples of non-noetherian rings, too. E.g. let E be a field and consider $R := E[t_i \mid 1 \leq i \in \mathbb{N}]$ the polynomial ring in (countably) infinitely many indeterminates. Then R is an integral domain but it is not noetherian. Just let $\mathfrak{p}_k := \langle t_1, t_2, \ldots, t_k \rangle_{\mathfrak{i}}$ be the prime ideal generated by the first k indeterminates. Then we obtain an infinitely ascending chain of (even prime) ideals $\mathfrak{p}_1 \subset \mathfrak{p}_2 \subset \ldots \subset \mathfrak{p}_k \subset \ldots$

- Non-noetherian rings may well lie inside of noetherian rings: As an example regard the ring $R = E[t_i \mid 1 \leq i \in \mathbb{N}]$ again. As R is an integral domain R is contained in its quotient field F. But as F is a field it in particular is noetherian.

- The standard example of an artinian ring in algebraic geometry is the following: Let R be a noetherian ring, e.g. $R = E[t_1, \ldots, t_n]$, where E is a field. Now pick up finitely many maximal ideals $\mathfrak{m}_1$ to $\mathfrak{m}_r$ of R and let $\mathfrak{j} := \mathfrak{m}_1 \cap \cdots \cap \mathfrak{m}_r$. Geometrically speaking any maximal ideal corresponds to a point and the intersection to the union of these. Then $A := R/\mathfrak{j}$ is an artinian ring: It is noetherian since R is and its only has the maximal ideals $\mathfrak{m}_i/\mathfrak{j}$. By construction these are only finitely many and it satisfies $\textsc{jac}(A) = \mathfrak{j}/\mathfrak{j} = 0 \subseteq \textsc{nil}(A) \subseteq \textsc{jac}(A)$. Hence A satisfies all the properties required in (e).

- As a counterexample consider the maximal ideal $\mathfrak{m} = \langle t_i \mid i \in \mathbb{N} \rangle_{\mathfrak{i}}$ in the polynomial ring of infinitely many variables $R = E[t_i \mid i \in \mathbb{N}]$ over the field E. Then the ring $S := R/\mathfrak{m}^2$ is not noetherian but only has maximal prime ideals (it is of Krull-dimension 0).

- ($\diamondsuit$) Another example from complex analysis: Let $\mathcal{O} := \{ f : \mathbb{C} \to \mathbb{C} \mid f \text{ holomorphic} \}$ be the ring of holomorphic functions on $\mathbb{C}$ [that this is isomorphic to the ring $\mathbb{C}\{z\}$ of globally convergent power series]. Now let $\mathfrak{a}_k := \{ f \in \mathcal{O} \mid \forall k \leq n \in \mathbb{N} : f(n) = 0 \}$. Clearly the $\mathfrak{a}_k \trianglelefteq_{\mathfrak{i}} \mathcal{O}$ are ideals of $\mathcal{O}$ they even form a strictly ascending chain of ideals (this is a special case of the Weierstrass product theorem). Again $\mathcal{O}$ is an integral domain (by the identity theorem of holomorphic functions) but - as we have just seen, or by the Weierstrass factorisation theorem - it is not noetherian.

(2.40) Proposition: (viz. 1033)
Let $(R,+,\cdot)$ be a commutative ring and fix $\star$ as an abbreviation for either of the words *noetherian* or *artinian*. Then the following statements hold true:

(i) If $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is an ideal and R is $\star$, then the quotient $R/\mathfrak{a}$ also is a $\star$ ring.

(ii) Let $(S,+,\cdot)$ be any ring and let $\varphi : R \twoheadrightarrow S$ be a surjective ring-homomorphism. If now R is a $\star$ ring, then S is a $\star$ ring, too.

(iii) Suppose R and S are commutative rings. Then the direct sum $R \oplus S$ is a $\star$ ring if and only if both R and S are $\star$ rings.

(2.41) Remark:
We are about to formulate Hilbert's basis theorem. Yet in order to do this we first straighten out a few things for the reader who is not familiar with the notion of an R-algebra. Consider a commutative ring $(S,+,\cdot)$ and a sub-ring $R \leq_{\mathrm{r}} S$ of it. Further let $E \subseteq S$ be any subset, then we introduce the R-sub-ring of S *generated* by E to be the following

$$R[E] := \left\{ \sum_{i=1}^{m} a_i \prod_{j=1}^{n} e_{i,j} \;\middle|\; m,n \in \mathbb{N},\ a_i \in R, e_{i,j} \in E \right\}$$

Nota that $0 \in R[X]$ as $m = 0$ and $1 \in R[E]$ as $n = 0$ are allowed. And thereby $R[E]$ is a sub-ring of S, containing R. In fact $R[E]$ is precisely the R-subalgebra of S generated by E in the sense of section 3.2. And for those who already know the notion of polynomials in several variables this can also be put in the following form

$$R[E] = \{ f(e_1,\ldots,e_n) \mid 1 \leq n \in \mathbb{N},\ f \in R[t_1,\ldots,t_n],\ e_i \in E \}$$

In particular if E is a finite set - say $E = \{ e_1,\ldots,e_n \}$ - we also write $R[e_1,\ldots,e_n] := R[E]$. And this is just the image of the polynomial ring $R[t_1,\ldots,t_n]$ under the evaluation homomorphism $t_i \mapsto e_i$.

(2.42) Theorem: (viz. 1035) **Hilbert Basis Theorem**
Let $(S,+,\cdot)$ be a commutative ring and consider a sub-ring $R \leq_{\mathrm{r}} S$. Further suppose that S is *finitely generated* (as an R-algebra) over R, that is there are finitely many $e_1,\ldots,e_n \in S$ such that $S = R[e_1,\ldots,e_n]$. If now R is a noetherian ring, then S is a noetherian ring, too

$$R \text{ noetherian} \quad\Longrightarrow\quad S = R[e_1,\ldots,e_n] \text{ noetherian}$$

($\diamondsuit$) An extension of this theorem is the *Noetherian Normalisation Theorem*, that we will formulate in section 8.4. It states that a finitely generated commutative algebra $A = F[e_1,\ldots,e_n]$ over a field F admits a sub-ring $S \leq_{\mathrm{r}} A$ such that $S \cong_{\mathrm{a}} F[t_1,\ldots,t_d]$ is isomorphic to a polynomial ring over F and A is finitely generated, as a module over S. However, for the time being, we have not introduced all the ingredients required for this.

(2.43) Remark:
The major work in proving Hilbert's Basis Theorem lies in regarding the polynomial ring $S = R[t]$. The rest is just induction and (2.40.(ii)). And for this we chose a constructive proof. That is given a non-zero ideal $0 \neq \mathfrak{u} \trianglelefteq_{\mathrm{i}} S$ we want to find a finite set of generators of $\mathfrak{u}$. To do this let

$$\mathfrak{a}_k \;:=\; \{\, \mathrm{lc}(f) \mid f \in \mathfrak{u},\ \deg(f) = k \,\} \cup \{0\}$$

As $\mathfrak{a}_k$ is an ideal of R it is finitely generated, say $\mathfrak{a}_k = \langle a_{k,1}, \ldots, a_{k,n(k)} \rangle_{\mathrm{i}}$ where $a_{k,i} = f_{k,i}$ for some $f_{k,i} \in \mathfrak{u}$ with $\deg(f_{k,i}) = k$ and $a_{k,i} = \mathrm{lc}(f_{k,i})$. Further the $\mathfrak{a}_k$ form an ascending chain and hence there is some $s \in \mathbb{N}$ such that $\mathfrak{a}_s = \mathfrak{a}_{s+1} = \mathfrak{a}_{s+2} = \ldots$. Then a trick argument shows

$$\mathfrak{u} \;=\; \langle f_{k,1} \mid k \in 0 \ldots s,\ i \in 1 \ldots n(k) \rangle_{\mathrm{i}}$$

(2.44) Definition:
Let $(R, +, \cdot)$ be any commutative ring and $\mathfrak{q}_\circ$, $\mathfrak{q} \trianglelefteq_{\mathrm{i}} R$ be a prime ideals of R. Then we say that $\mathfrak{q}_\circ$ **lies directly** under $\mathfrak{q}$ if $\mathfrak{q}_\circ$ is maximal among the prime ideals contained in $\mathfrak{q}$. And we abbreviate this by writing $\mathfrak{q}_\circ \subset_* \mathfrak{q}$. Formally that is

$$\begin{aligned} \mathfrak{q}_\circ \subset_* \mathfrak{q} \quad &:\Longleftrightarrow \quad \mathfrak{q}_\circ \in \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{p} \subset \mathfrak{q} \,\}^* \\ &\Longleftrightarrow \quad (1)\ \ \mathfrak{q}_\circ \in \mathrm{Spec}(R) \text{ with } \mathfrak{q}_\circ \subset \mathfrak{q} \\ &\qquad\quad\ (2)\ \ \forall\ \mathfrak{p} \in \mathrm{Spec}(R)\ :\ \mathfrak{q}_\circ \subseteq \mathfrak{p} \subseteq \mathfrak{q} \implies \mathfrak{q}_\circ = \mathfrak{p} \text{ or } \mathfrak{p} = \mathfrak{q} \end{aligned}$$

(2.45) Proposition: (viz. 1037)
Let $(R, +, \cdot)$ be a noetherian ring, then we find the truth of the following four statements

(i) Any non-empty set of ideals of R contains a maximal element. That is for any $\mathcal{A} \subseteq \mathrm{Ideal}(R)$ with $\mathcal{A} \neq \emptyset$ there is some $\mathfrak{a}^* \in \mathcal{A}$ that satisfies the following property

$$\forall\, \mathfrak{a} \in \mathcal{A} \text{ we get } \mathfrak{a}^* \subseteq \mathfrak{a} \quad\Longrightarrow\quad \mathfrak{a}^* = \mathfrak{a}$$

(ii) Any non-empty set of prime ideals of R contains maximal and minimal elements. That is for any non-empty $\mathcal{P} \neq \emptyset$ set of prime ideals $\mathcal{P} \subseteq \mathrm{Spec}(R)$ of R we get

$$\mathcal{P}_* \neq \emptyset \quad \text{and} \quad \mathcal{P}^* \neq \emptyset$$

(iii) In particular for any two prime ideals $\mathfrak{p}$, $\mathfrak{q} \trianglelefteq_{\mathrm{i}} R$ with $\mathfrak{p} \subset \mathfrak{q}$ there is a prime ideal $\mathfrak{q}_\circ$ lying directly under $\mathfrak{q}$. Formally that is the following statement

$$\exists\ \mathfrak{q}_\circ \in \mathrm{Spec}(R)\ :\ \mathfrak{p} \subseteq \mathfrak{q}_\circ \subset_* \mathfrak{q}$$

(iv) Let $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be any proper ideal, i.e. $\mathfrak{a} \neq R$, then there only are finitely many prime ideals lying minimally over $\mathfrak{a}$. Formally that is the following statement

$$1 \;\leq\; \#\{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p} \,\}_* \;<\; \infty$$

(2.46) Proposition: (viz. 906)
Let $(R, +, \cdot)$ be an artinian ring, then we find the truth of the following seven statements

(i) An artinian integral domain already is a field.

(ii) Any artinian ring already is a noetherian ring.

(iii) In an artinian ring R maximal, prime and minimal prime ideals all coincide, in terms of the spectra:

$$\mathrm{Smax}(R) \;=\; \mathrm{Spec}(R) \;=\; \mathrm{Smin}(R)$$

(iv) Any artinian ring already is semilocal, that is it only has finitely many maximal ideals.

(v) In an artinian ring the Jacobson radical and the nil-radical coincide and are nilpotent, put formally

$$\textsc{jac}(R) \;=\; \textsc{nil}(R) \quad \text{and} \quad \exists\, n \in \mathbb{N} : (\textsc{jac}(R))^n = 0$$

(vi) For an artinian ring R the reduction $R/\textsc{nil}(R)$ is isomorphic to the (finite) direct sum of its residue fields. And we can even give the isomorphism explicitly to be

$$R\Big/_{\textsc{nil}(R)} \;\cong_{\mathrm{r}}\; \bigoplus_{\mathfrak{m} \,\in\, \mathrm{smax}(R)} R\Big/_{\mathfrak{m}} \;:\; a + \textsc{nil}(R) \mapsto (a + \mathfrak{m})$$

(vii) An artinian ring R can be decomposed into a finite number of local artinian rings. That is there are local, artinian rings L_i such that we get an isomorphy

$$R \;\cong_{\mathrm{r}}\; L_1 \oplus \cdots \oplus L_r$$

Nota Thereby $r := \#\mathrm{Smax}(R)$ is the number of maximal ideals of R and any L_i is of the form $L_i = R/\mathfrak{m}_i^n$ where $n \in \mathbb{N}$ such that $(\textsc{jac}(R))^n = 0$. The isomorphism is natural: $a \mapsto (a + \mathfrak{m}_i^n)$.

(2.47) Corollary: (viz. 1036)
Let $(R, +, \cdot)$ be any commutative ring, then R is the union of a net of noetherian sub-rings. That is there is a family (R_i) (where $i \in I$) of sub-rings such that the following statements hold true

(1) $R_i \;\leq_{\mathrm{r}}\; R$ is a sub-ring for any $i \in I$

(2) R_i is a noetherian ring for any $i \in I$

(3) $R = \bigcup_{i \in I} R_i$

(4) $\forall\, i, j \in I \;\exists\, k \in I$ such that $R_i \cup R_j \;\subseteq\; R_k$

2.5 Unique Factorisation Domains

The reader most probably is aware of the fact, that any integer $n \in \mathbb{Z}$ (apart from 0) admits a decomposition into primes. In this and the next section we will study what kinds of rings qualify to have this property. We will see that noetherian integral domains come close, but do not suffice. And we will see that PIDs will allow prime decomposition. That is the truth lies somewhere in between but cannot be pinned down precisely.
According to the good, old traditions of mathematics we're in for a definition: A ring will simply said to be *factorial*, iff it allows prime decomposition (a mathematical heretic might object: "If you can't prove it, define it!"). Then PIDs are factorial. And the lemma of Gauss is one of the few answers in which cases the factorial property is preserved.
So we have to start with a lengthy series of (luckily very easy) definitions. But once we have assembled the language needed for prime decomposition we will be rewarded with several theorems of great beauty - the fundamental theorem of arithmetic at their center.

(2.48) Definition: (viz. 1038)
Let $(R, +, \cdot)$ be a commutative ring and $a, b \in R$ be two elements of R. Then we say that a **divides** b (written as $a \mid b$) iff one of the following three equivalent properties is satisfied

(a) $b \in aR$

(b) $bR \subseteq aR$

(c) $\exists\, h \in R \;:\; b = ah$

And we define the **order** of a in b to be the highest number $k \in \mathbb{N}$ such that a^k still divides b (if a^k divides b for any $k \in \mathbb{N}$, then the order of a in b is taken to be ∞)

$$\langle a \mid b \rangle \;:=\; \sup\Big\{\, k \in \mathbb{N} \mid b \in a^k R \,\Big\} \;\in\; \mathbb{N} \cup \{\infty\}$$

We say that a and b are **associated**, which we will denote as $a \approx b$ iff there is some unit $\alpha \in R^*$ such that $b = \alpha a$. And if R is an integral domain then $a \approx b$ is true, iff one of the following three equivalent properties is satisfied

(a) $aR = bR$

(b) $a \mid b$ and $b \mid a$

(c) $\exists\, \alpha \in R^* \;:\; b = \alpha a$

(2.49) Remark:

(i) By construction $\approx$ is an equivalence relation on R, that $\approx$ is a reflexive, symmetric and transitive relation. And for any $a \in R$ the equivalence class of $a \in R$ is given to be $[a] = R^* a := \{\, \alpha a \mid \alpha \in R^* \,\}$. In particular we have $[0] = 0$ and $[1] = R^*$.

Prob we have $a \approx a$, as $a = 1 \cdot a$ and if $b = \alpha a$ for some $\alpha \in R^*$ then also $a = \alpha^{-1} b$ such that $a \approx b$ also implies $b \approx a$. Finally if $a \approx b$ and $b \approx x$ then we have $b = \alpha a$ and $c = \beta b$ such that $c = \beta\alpha a$ and as $\beta\alpha \in R^*$ (with inverse $\alpha^{-1}\beta^{-1}$) again, this is $a \approx c$.

(ii) If R is an integral domain and $a, b \in R$ such that $a \neq 0$ and $a \mid b$ then the *divisor* $h \in R$ satisfying $b = ah$ is uniquely determined. As we sometimes wish to refer to the divisor, it deserves a name of its own. Hence if R is an integral domain, $a, b \in R$ with $a \neq 0$ and $a \mid b$ we let

$$\frac{a}{b} := h \quad \text{such that} \quad b = ah$$

Prob we have to show the uniqueness: Thus suppose $b = ag$ and $b = ah$ then $a(g - h) = 0$. And as $a \neq 0$ and R is an integral domain this yields $g - h = 0$ and hence $g = h$.

(2.50) Example:
Let $(R, +, \cdot)$ be an commutative ring and $a, b \in R$. Let us denote the ideal generated by a and b by $\mathfrak{a} := aR + bR$. Now consider any polynomial $f \in R[t]$, $1 \leq k \in \mathbb{N}$ and let $d := \deg(f)$. Then a straightforward computation yields

$$f(a)a^k - f(b)b^k \;=\; (a-b)\left(\sum_{i=0}^{d} f[i] \sum_{j=0}^{k-1+i} a^j b^{k-j}\right)$$

A special case of this is the third binomial rule $a^2 - b^2 = (a - b)(a + b)$ which is obtained by letting $f(t) := t$. Thus this cumbersome double sum on the right is the divisor of $f(a)a^k - f(b)b^k$ times $a - b$. And in the case of an integral domain (and $a \neq b$) this even is uniquely determined. And from the explicit representation of the divisor one also finds

$$\frac{f(a)a^k - f(b)b^k}{a-b} \;=\; \sum_{i=0}^{d} f[i] \sum_{j=0}^{k-1+i} a^j b^{k-j} \;\in\; \mathfrak{a}^{k-1}$$

(2.51) Proposition: (viz. 1038)

(i) Let $(R, +, \cdot)$ be any commutative ring then for any a, b and $c \in R$ the relation of divisibility satisfies all of the following properties

$$\begin{aligned} 1 &\mid b \\ a &\mid 0 \\ a &\mid ab \\ 0 \mid b \quad &\Longleftrightarrow \quad b = 0 \\ a \mid 1 \quad &\Longleftrightarrow \quad a \in R^* \\ a \mid b \quad &\Longrightarrow \quad ac \mid bc \end{aligned}$$

(ii) If a, b and $u \in R$ such that $u \in \mathrm{NZD}(R)$ is a non-zero divisor of R, then we find the equivalence of

$$a \mid b \quad \Longleftrightarrow \quad au \mid bu$$

(iii) If $(R, +, \cdot)$ is an integral domain, then *divisibility* is a reflexive, transitive relation that is antisymmetric up to associativity. Formally that is: For any a, b and $c \in R$ we get

$$\begin{aligned} a &\mid a \\ a \mid b \text{ and } b \mid c &\implies a \mid c \\ a \mid b \text{ and } b \mid a &\implies a \approx b \end{aligned}$$

(2.52) Remark:
Let $(R, +, \cdot)$ be a commutative ring, recall that we have defined the set of **relevant** elements of R to be the non-zero, non-units of R, that is

$$R^\bullet \;:=\; R \setminus \left(R^* \cup \{0\}\right)$$

- $R^\bullet = \emptyset$ is empty if and only if $R = 0$ or R is a field.

 Prob if $R = 0$ then trivially $R^\bullet = \emptyset$. Conversely $R^\bullet = \emptyset$ if and only if $R = R^* \cup \{0\}$ or in yet other words, if $R^* = R \setminus \{0\}$. And this is just the definition of R being a field.

- The complement of $R^\bullet$ is multiplicatively closed (which means $1 \notin R^\bullet$ and $a, b \notin R^\bullet \implies ab \notin R^\bullet$)

 $$R \setminus R^\bullet \;=\; R^* \cup \{0\} \text{ is multiplicatively closed}$$

 Prob first of all we have $1 \in R^* \cup \{0\} = R \setminus R^\bullet$ (whether $R = 0$ or not). Now consider $a, b \in R \setminus R^\bullet$. If $a = 0$ or $b = 0$ then $ab = 0$ and hence $ab \in R \setminus R^\bullet$. Else if $a, b \neq 0$ then $a, b \in R^*$ and hence $ab \in R^*$, as the inverse of ab can be given, to be $b^{-1}a^{-1} \in R$.

- If R is an integral domain, then $R^\bullet$ is stable under multiplication with non-zero elements: That is, if $a, r \in R$ with $a \neq 0$ and $r \in R^\bullet$, then we get $ar \in R^\bullet$ again.

 Prob if we had $ar = 0$, then $a = 0$ or $r = 0$, as R is an integral domain. But this is not the case. Suppose $ar \in R^*$, that is $aru = 1$ for some $u \in R$. Then $r(au) = 1$ such that $r \in R^*$ with inverse au. But as $r \in R^\bullet$ this is untrue, as well, such that $ar \in R^\bullet$.

(2.53) Definition:
Let $(R, +, \cdot)$ be a commutative ring and $p \in R$ be an elements of R. Then p is said to be **irreducible** if p is a relevant element of R but cannot be further factored into relevant elements. Formally iff

(1) $p \in R^\bullet$

(2) $\forall\, a, b \in R : \; p = ab \implies a \in R^*$ or $b \in R^*$

Likewise $p \in R$ is said to be a **prime** element of R, iff it is a relevant element of R such that it divides (at least) one of the factors in every product it divides. Formally again, iff

(1) $p \in R^\bullet$

(2) $\forall\, a, b \in R : \; p \mid ab \implies p \mid a$ or $p \mid b$

(2.54) Definition:
Let $(R,+,\cdot)$ be a commutative ring and $a \in R$ and let $\star$ abbreviate either the word *prime* or the word *irreducible*. Then a tupel $(\alpha, p_1, \ldots, p_k)$ (with $k \in \mathbb{N}$ and $k = 0$ allowed!) is said to be a $\star$ **decomposition** of a, iff all of the following three properties are satisfied

(1) $\alpha \in R^*$

(2) $a \;=\; \alpha p_1 \ldots p_k$

(3) $\forall\, i \in 1 \ldots n :\; p_i \in R$ is $\star$

If $(\alpha, p_1, \ldots, p_k)$ at least satisfies (1) and (3) then let us agree to call it a $\star$ **series**. Now any two $\star$ series $(\alpha, p_1, \ldots, p_k)$ and $(\beta, q_1, \ldots, q_l)$ are said to be **essentially equal** [which we will denote by writing $(\alpha, p_1, \ldots, p_k) \approx (\beta, q_1, \ldots, q_l)$], iff they are of the same length, ddeompose the same element and their entries are pairwise associated. Formally $(\alpha, p_1, \ldots, p_k) \approx (\beta, q_1, \ldots, q_l) \;:\Longleftrightarrow$ (1), (2) and (3) where

(1) $k = l$

(2) $\alpha p_1 \ldots p_k \;=\; \beta q_1 \ldots q_l$

(3) $\exists\, \sigma \in S_k :\; \forall\, i \in 1 \ldots k :\; p_i \approx q_{\sigma(i)}$

(2.55) Example: $(\diamondsuit)$
Let $(R,+,\cdot)$ be an integral domain and $a \in R$, then the linear polynomial $p(t) := t - a \in R[t]$ is prime. Note that this need not be true unless R is an integral domain. E.g. for $R = \mathbb{Z}_6$ we have

$$t - 1 = (2t+1)(3t-1) \quad \text{but} \quad t - 1 \not\mid 2t+1,\; t-1 \not\mid 3t-1$$

Prob consider $f, g \in R[t]$ such that $p \mid fg$. that is there is some $h \in R[t]$ such that $(t-a)h = fg$. In particular $f(a)g(a) = (fg)(a) = (a-a)h(a) = 0$. As R is an integral domain this means $f(a) = 0$ or $g(a) = 0$. And from this again we get $p = t - a \mid f$ or $p = t - a \mid g$.

(2.56) Definition:

- Let $(R,+,\cdot)$ be a commutative ring again and $\emptyset \neq A \subseteq R$ be a non-empty subset of R. Then we say that $m \in R$ is a **common multiple** of A, iff every $a \in A$ divides m, formally

$$A \mid m \quad :\Longleftrightarrow \quad \forall\, a \in A \;:\; a \mid m$$

- And thereby m is said to be a **least common multiple** of A, iff m is a common multiple that divides any other common multiple. That is iff m satisfies

 (1) $A \mid m$

 (2) $\forall\, n \in R :\; A \mid n \implies m \mid n$

 And we will denote the set of least common multiples of A by $\operatorname{lcm}(A) := \{\, m \in R \mid (1) \text{ and } (2) \,\}$.

- Analogous to the above we say that an element $d \in R$ is a **common divisor** of A, iff d divides every $a \in A$. We will denote this, by

$$d \mid A \quad :\Longleftrightarrow \quad \forall\, a \in A \,:\, d \mid a$$

- And thereby d is said to be a **greatest common divisor** of A, iff d is a common divisor that is divided by any other common divisor. That is iff d satisfies

 (1) $d \mid A$
 (2) $\forall\, c \in R : c \mid A \implies c \mid d$

 And we will denote the set of greatest common divisors of A by $\gcd(A) := \{\, d \in R \mid (1) \text{ and } (2) \,\}$.

- Finally A is said to **relatively prime**, iff 1 is a greatest common divisor of A. By abuse of notation a finite family of elements $a_1, \ldots, a_k \in R$ is said to be *relatively prime*, iff the set $\{a_1, \ldots, a_k\}$ is relatively prime. By (2.51.(i)) this property can also be formulated, as

$$\begin{aligned} A \text{ relatively prime} \quad &:\Longleftrightarrow \quad 1 \in \gcd(A) \\ &\Longleftrightarrow \quad \forall\, c \in R \;:\; c \mid A \implies c \in R^* \end{aligned}$$

(2.57) Remark: (viz. 1040)

(i) A special case is $A = \{\, a \,\}$ for some $a \in R$. For such a singleton we trivially have $a \in \operatorname{lcm}(A)$ and $a \in \gcd(A)$. And if R is an integral domain then (2.58.(ix)) tells us that thereby

$$\operatorname{lcm}(A) \;=\; \gcd(A) \;=\; aR^*$$

In particular we get $\operatorname{lcm}(1) = \gcd(1) = R^*$ and $\operatorname{lcm}(0) = \gcd(0) = \{0\}$.

(ii) If $A \neq \emptyset$ then picking up 1 does not change the least common multiple and picking up 0 does not change the greatest common divisor

$$\begin{aligned} \operatorname{lcm}\big(A \cup \{\, 1 \,\}\big) &= \operatorname{lcm}(A) \\ \gcd\big(A \cup \{0\}\big) &= \gcd(A) \end{aligned}$$

(iii) In a general commutative ring R for any non-empty subset $A \subseteq R$ we find that $0 \in \gcd(A)$ is equivalent to $A = \{0\}$. In formal terms

$$0 \in \gcd(A) \quad \Longleftrightarrow \quad A = \{0\}$$

And if R is an integral domain and $A \subseteq R$ is non-empty and finite, then $0 \in \operatorname{lcm}(A)$ also is equivalent to to $A = \{0\}$. In formal terms again

$$0 \in \operatorname{lcm}(A) \quad \Longleftrightarrow \quad A = \{0\}$$

(iv) If A is an infinite subset, then $\operatorname{lcm}(A)$ may be zero, as well: As an example consider $R = \mathbb{Z}$ and $A = \mathbb{N}$, then $A \mid k$ is equivalent to $k = 0$ and hence $\operatorname{lcm}(A) = \{0\}$.

(2.58) Proposition: (viz. 1038)

(i) Let $(R,+,\cdot)$ be a commutative ring, $p \in R$ be a prime element and $a_1,\ldots,a_k \in R$ be arbitrary elements of R. Then we obtain the following implication

$$p \mid \prod_{i=1}^{k} a_i \quad \Longrightarrow \quad \exists\, i \in 1\ldots k \,:\, p \mid a_i$$

(ii) Let $(R,+,\cdot)$ be a commutative ring and $p \in R$. Then p is a prime element iff $p \neq 0$ and the principal ideal $pR \trianglelefteq_{\mathrm{i}} R$ is a prime ideal, formally that is

$$p \in R \text{ prime} \quad \Longleftrightarrow \quad p \neq 0 \;\text{ and }\; pR \trianglelefteq_{\mathrm{i}} R \text{ prime}$$

(iii) Let $(R,+,\cdot)$ be a commutative ring, $p \in R$ and $\alpha \in R^*$ a unit of R. Let us again abbreviate the word *prime* or *irreducible* by $\star$, then we have the equivalences of

$$p \text{ is } \star \quad \Longleftrightarrow \quad \alpha p \text{ is } \star$$

(iv) Let $(R,+,\cdot)$ be an integral domain. Then any prime element of R already is irreducible. That is for any $p \in R$ we find the following implication

$$p \text{ is prime} \quad \Longrightarrow \quad p \text{ is irreducible}$$

(v) Let $(R,+,\cdot)$ be an integral domain $0 \neq a \in R$ and $b \in R^\bullet$ be a non-zero non-unit. Then we obtain the following strict inclusion of ideals

$$(ab)R \quad \subset \quad aR$$

(vi) Let $(R,+,\cdot)$ be an integral domain and consider a non-unit $f \in R \setminus R^*$ and a prime element $p \in R$. If f divides p, then f and p already are associates (and vice versa), which is the equivalence

$$f \mid p \quad \Longleftrightarrow \quad f \approx p$$

(vii) Let $(R,+,\cdot)$ be an integral domain, consider some elements $a, b \in R$ and suppose $d \in \gcd\{a,b\}$ is a greatest common divisor of a and b. Then the elements a/d and $b/d \in R$ are relatively prime

$$d \in \gcd\{a,b\} \quad \Longrightarrow \quad 1 \in \gcd\left\{\frac{a}{d}, \frac{b}{d}\right\}$$

(viii) Let $(R,+,\cdot)$ be an integral domain. Then the set D of all $d \in R$ that allow a prime decomposition is saturated and multiplicatively closed. That is $D := \{\alpha p_1 \ldots p_k \mid \alpha \in R^*,\ k \in \mathbb{N},\ p_i \in R \text{ prime}\}$ satisfies the properties

$$\begin{aligned} 1 \quad &\in \quad D \\ c,d \in D \quad &\Longleftrightarrow \quad cd \in D \end{aligned}$$

(ix) Let $(R,+,\cdot)$ be an integral domain and suppose $p_1,\ldots,p_k$ and $q_1,\ldots,q_l \in R$ are finite collections of prime elements of R (where k, $l \in \mathbb{N}$ with $k = 0$ and $l = 0$ allowed) and let α, $\beta \in R^*$ be two units of R. Then the prime decompositions are essentially equal, that is

$$\alpha p_1 \ldots p_k = \beta q_1 \ldots q_l \quad \Longrightarrow \quad \begin{array}{l} k = l \text{ and } \exists\, \sigma \in S_k \text{ such that} \\ \forall\, i \in 1 \ldots k \;:\; p_i \approx q_{\sigma(i)} \end{array}$$

(x) Let $(R,+,\cdot)$ be an integral domain and $\emptyset \neq A \subseteq R$ be a non-empty subset of R. Further let d and $m \in R$ be two elements of R, then we find the equivalences

$$\begin{aligned} m \in \operatorname{lcm}(A) &\iff \operatorname{lcm}(A) = mR^* \\ d \in \gcd(A) &\iff \gcd(A) = dR^* \end{aligned}$$

(2.59) Theorem: (viz. 1041)
Let $(R,+,\cdot)$ be a noetherian integral domain and fix some elements a, b and $p \in R$ where p is prime. Then we obtain the following statements

(i) If $a \in R^\bullet$ then the order in which a divides b is finite. In formal terms we get

$$\langle a \mid b \rangle \;\in\; \mathbb{N}$$

(ii) The order of a prime element $p \in R$ has the properties of a logarithm - it turns multiplications into additions and powers ($n \in \mathbb{N}$) into multiples. That is

$$\begin{aligned} \langle p \mid ab \rangle &= \langle p \mid a \rangle + \langle p \mid b \rangle \\ \langle p \mid a^n \rangle &= n \cdot \langle p \mid a \rangle \end{aligned}$$

(iii) Any $a \neq 0$ admits an irreducible decomposition. That is there are some $\alpha \in R^*$ and finitely many irreducible elements $p_1,\ldots,p_k \in R$ such that a can be written, as

$$a \;=\; \alpha p_1 \ldots p_k$$

(iv) If $0 \neq \mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ is any prime ideal of R then $\mathfrak{p}$ is generated by finitely many irreducible elements. That is there are $p_1,\ldots,p_k \in R$ irreducible, such that

$$\mathfrak{p} \;=\; \langle p_1,\ldots,p_k \rangle_{\mathrm{i}}$$

(v) Let $P \subseteq R^\bullet$ be a set of pairwise non-associate non-zero non-units of R. That is we assume that for any p, $q \in P$ we get $p \approx q \implies p = q$. Then for any $a \neq 0$ the number of $p \in P$ that divide a is finite, formally again we get

$$\#\{\, p \in P \mid a \in pR \,\} \;<\; \infty$$

(vi) Let $b \in R^\bullet$ be a non-zero, non-unit of R. Further consider a finite collection $q_1, \ldots, q_k \in R$ of prime elements of R that are pairwise non-associate. That is we assume $q_i \approx q_j \implies i = j$ for any i, $j \in 1 \ldots k$. Then we obtain the divisibility relation

$$a \;:=\; \prod_{i=1}^{k} q_i^{\langle q_i | b \rangle} \;\Big|\; b$$

In particular, if $q_i \mid b$ for any $i \in 1 \ldots k$ then $q_1 \ldots q_k \mid a$ and hence $q_1 \ldots q_k \mid b$. If now $p \in R$ is any prime element of R, then we obtain another implication

$$p \mid b \quad\Longrightarrow\quad p \mid \frac{b}{a} \quad \text{xor} \quad \exists\, i \in 1 \ldots k : p \approx q_i$$

(2.60) Definition: (viz. 1044)
We call $(R, +, \cdot)$ an **unique factorisation domain** (which we will always abbreviate by **UFD**), iff R is an integral domain that further satisfies one of the following equivalent properties

(a) Every non-zero element admits a decomposition into prime elements. That is for any $0 \neq a \in R$ we get the following statement

$$\exists\ (\alpha, \mathbf{p}) = (\alpha, p_1, \ldots, p_k) \text{ prime decomposition of } a$$

(b) Every non-zero element admits an essentially unique decomposition into irreducible elements. That is for any $a \in R$ with $a \neq 0$ we have

(1) $\exists\, (\alpha, \mathbf{p}) = (\alpha, p_1, \ldots, p_k)$ irreducible decomposition of a

(2) $(\alpha, \mathbf{p}), (\beta, \mathbf{q})$ irreducible decompositions of $a \implies (\alpha, \mathbf{p}) \approx (\beta, \mathbf{q})$

(c) Every non-zero element admits a decomposition into irreducible elements and every irreducible element is prime. Formally these are both of the properties

(1) $\forall\, 0 \neq a \in R\ \ \exists\, (\alpha, \mathbf{p})$ irreducible decomposition of a

(2) $\forall\, p \in R \ :\ p$ prime $\iff p$ irreducible

(d) The principal ideals of R satisfy the ascending chain condition and every irreducible element is prime. Formally these are both of the properties

(1) for any family of elements $a_k \in R$ (where $k \in \mathbb{N}$) of R such that $a_0 R \subseteq a_1 R \subseteq \ldots \subseteq a_k R \subseteq a_{k+1} R \subseteq \ldots$ there is some $s \in \mathbb{N}$ such that for any $i \in \mathbb{N}$ we get $a_{s+i} R = a_s R$.

(2) $\forall\, p \in R \ :\ p$ prime $\iff p$ irreducible

(e) Any non-zero prime ideal of R contains a prime element of R. Let us add a formal version of this:

$$\forall\, \mathfrak{p} \in \operatorname{Spec}(R) \ :\ \mathfrak{p} \neq 0 \quad\Longrightarrow\quad \exists\, p \in R \text{ prime} \ :\ p \in \mathfrak{p}$$

(f) ($\diamondsuit$) Let $D := \{\alpha p_1 \dots p_k \mid \alpha \in R^*,\ k \in \mathbb{N},\ p_i \in R \text{ prime}\}$ denote the set of all elements $d \in R$ that allow a prime decomposition again. Then either $R = 0$ is the zero ring or the quotient field of R is precisely the localization of R in D, formally

$$\text{QUOT}(R) \ = \ D^{-1}R$$

(2.61) Remark:

- The zero-ring $R = 0$ trivially is an UFD. As it does not contain a single non-zero element such that condition (a) of UFDs is void (hence true).
- Property (b) guarantees that - in an UFD $(R, +, \cdot)$ - any nonzero element $0 \neq a \in R$ admits an irreducible (equivalently prime) decomposition $a = \alpha p_1 \dots p_k$, that even is essentially unique. And this uniqueness determines the number k of irreducible factors. Hence we may define the **length** of a to be precisely this number

$$\ell(a) \ := \ k \quad \text{where} \quad (\alpha, p_1, \dots, p_k) \text{ prime decomposition of } a$$

- Any field $(E, +, \cdot)$ is an UFD, as we allowed $k = 0$ for a prime decomposition $(\alpha, p_1, \dots, p_k)$. To be precise if $0 \neq a \in E$ then $a \in E^*$ already is a unit and hence (a) is a prime decomposition of a.
- In the next section we will prove that any PID (i.e. an integral domain in which every ideal can be generated by a single element) is an UFD.
- If $(R, +, \cdot)$ is a noetherian integral domain in which any irreducible element is prime, then R is an UFD. This is clear from property (d) in (2.60).
- If $(R, +, \cdot)$ is an UFD then so is the polynomial ring $R[t]$ (this is the one of the lemmas of Gauss that will be proved in (7.29), all of which are milestones).
- ($\diamondsuit$) If $(R, +, \cdot)$ is an UFD and $U \subseteq R$ is multiplicatively closed, then the localisation $U^{-1}R$ is an UFD too. In fact, if $p \in R$ is a prime element then $p/1$ either is a unit or a prime in $U^{-1}R$. This will be proved in (2.131).
- ($\diamondsuit$) A sub-ring $\mathcal{O} \ \leq_{\mathrm{r}} \ \mathbb{C}$ of the complex numbers is said to be an *algebraic number ring*, iff any $a \in \mathcal{O}$ satisfies an integral equation over $\mathbb{Z}$ (that is there is a monic polynomial $f \in \mathbb{Z}[t]$ such that $f(a) = 0$). We will see that any algebraic number ring $\mathcal{O}$ is a Dedekind domain. And it is also true, that $\mathcal{O}$ is an UFD if and only if it is a PID.
- This list of UFDs is almost exhaustive. At the end of this section we will append a list of counter examples, such that the reader may convince himself that the equivalences in the definition of an UFD cannot be generalized.

(2.62) Remark:
It is often useful not to regard all the prime (resp. irreducible) elements of R but to restrict to a representative set modulo associateness. That is a subset $\mathbb{P} \subseteq R$ such that we have bijection of the form

$$\mathbb{P} \ \longleftrightarrow \ \{\, p \in R \mid p \text{ prime} \,\} \Big/_{\approx} \ : \ p \mapsto pR^*$$

Prob this is possible since $\approx$ is an equivalence relation on R of which the equivalence classes are precisely aR^* by (2.51). In particular $\approx$ also is on equivalence relation on the subset P of prime elements of R. And by (2.58) we know that for any $p \in P$ we have $[p] = \{\, q \in P \mid p \approx q \,\} = pR^*$ again. Hence we may choose $\mathbb{P}$ as a representing system of $P/\approx$ by virtue of the axiom of choice.

(2.63) Example:

- The units of the integers $\mathbb{Z}$ are given to be $\mathbb{Z}^* = \{-1, +1\}$. That is associateness identifies all elements having the same absolute value, $a\mathbb{Z}^* = \{-a, a\}$. And thereby we can choose a representing system of $\mathbb{Z}$ modulo $\approx$ simply by choosing all *positive* elements $a \geq 0$. Thus we find a representing system of the prime elements of $\mathbb{Z}$ by

$$\mathbb{P} \;:=\; \{\, p \in \mathbb{Z} \mid p \text{ prime}, \; 0 \leq p \,\}$$

- ($\diamondsuit$) Now let $(E, +, \cdot)$ be any field and consider the polynomial $E[t]$. Then we will see that the units of $E[t]$ are given to be $E[t]^* = E^* = \{at^0 \mid 0 \neq a \in E\}$. Thus associateness identifies all polynomials having the same coefficients up to a common factor. That is we get $fE[t]^* = \{af \mid 0 \neq a \in E\}$. Thus by requiring a polynomial f to be *normed* (i.e. $f[\deg(f)] = 1$) we eliminate this ambiguity. Therefore we find a representing system of the prime elements of $E[t]$ by

$$\mathbb{P} \;:=\; \{\, p \in E[t] \mid p \text{ prime, normed} \,\}$$

(2.64) Theorem: (viz. 1045)
Let $(R, +, \cdot)$ be an UFD, $p \in R$ be a prime element and $0 \neq a, b \in R$ be any two non-zero elements. Then the following statements hold true

(i) Suppose $(\alpha, p_1, \ldots, p_k)$ is a prime decomposition of a. Then for any prime $p \in R$ the order of p in a can be expressed as the number of appearances of an associate of p in the decomposition:

$$\langle p \mid a \rangle \;=\; \#\{\, i \in 1 \ldots k \mid p \approx p_i \,\} \;\in\; \mathbb{N}$$

(ii) (As in noetherian integral domains) the order of a prime element $p \in R$ has the properties of a logarithm - it turns multiplications into additions and powers ($n \in \mathbb{N}$) into multiples

$$\begin{aligned} \langle p \mid ab \rangle &= \langle p \mid a \rangle + \langle p \mid b \rangle \\ \langle p \mid a^n \rangle &= n \cdot \langle p \mid a \rangle \end{aligned}$$

(iii) We can reformulate divisibility like: a divides b if and only if for any prime p the order of p in a does not exceed the order of p in b. Formally that is the equivalence of

$$a \mid b \quad\Longleftrightarrow\quad \forall\, p \in R \text{ prime} : \langle p \mid a \rangle \leq \langle p \mid b \rangle$$

(iv) If $d \in R$ divides ab but a and d are relatively prime, then d already divides b. Formally that is the following implication

$$d \mid ab \text{ and } 1 \in \gcd\{a, d\} \implies d \mid b$$

(v) Let $\mathbb{P}$ be a representing system of the prime elements modulo associateness. Then for any $0 \neq a \in R$ we obtain a unique representation

$$\exists!\, \alpha \in R^* \;\; \exists!\, n = (n(p)) \in \bigoplus_{p \in \mathbb{P}} \mathbb{N} \;\; : \;\; a = \alpha \prod_{p \in \mathbb{P}} p^{n(p)}$$

and thereby we even have $n(p) = \langle p \mid a \rangle$ such that the sum of all $n(p)$ is precisely the length of a (and in particular finite). Formally that is

$$\ell(a) \;\; = \;\; \sum_{p \in \mathbb{P}} n(p) \;\; < \;\; \infty$$

Nota that $n \in \oplus_p \mathbb{N}$, that is $n : \mathbb{P} \to \mathbb{N}$ is a map such that the number of $p \in \mathbb{P}$ with $n(p) \neq 0$ is finite. And hence the product over all $p^{n(p)}$ (where $p \in \mathbb{P}$) well-defined using the notations of section 1.3.

(vi) Let $\mathbb{P}$ be a representing system of the prime elements modulo associateness again. And consider a non-empty subset $\emptyset \neq A \subseteq R$ such that $0 \notin A$. Then A has a greatest common divisor, namely

$$\prod_{p \in \mathbb{P}} p^{m(p)} \in \gcd(A) \quad \text{where} \quad m(p) := \min\{\, \langle p \mid a \rangle \mid a \in A \,\}$$

Likewise if $A = \{a_1, \ldots, a_n\} \subseteq R$ is a non-empty, finite ($1 \leq n \in \mathbb{N}$) subset with $0 \notin A$ then A has a least common multiple, namely

$$\prod_{p \in \mathbb{P}} p^{n(p)} \in \operatorname{lcm}(A) \quad \text{where} \quad n(p) := \max\{\, \langle p \mid a \rangle \mid a \in A \,\}$$

(vii) Let $A := \{\, a, b \,\}$ and $d \in \gcd(A)$ be a greatest common divisor, $m \in \operatorname{lcm}(A)$ a least common multiple of a and b. Then we obtain

$$ab \;\; \approx \;\; dm$$

(vii) If $0 \neq a, b, c \in R$ are any three non-zero elements of R, then the least common multiple and greatest common divisor of these can be evaluated recursively. That is if $d \in \gcd\{a, b\}$ and $m \in \operatorname{lcm}\{a, b\}$ then we get the recursion formuale

$$\begin{aligned} \gcd\{\, a, b, c \,\} &= \gcd\{\, d, c \,\} \\ \operatorname{lcm}\{\, a, b, c \,\} &= \operatorname{lcm}\{\, m, c \,\} \end{aligned}$$

(2.65) Proposition: (viz. 1047) ($\diamondsuit$)
Any UFD R is a normal domain. Thereby a commutative ring $(R, +, \cdot)$ is said to be *normal* (or *integrally closed*), iff R is integrally closed in its total ring of fractions. That is R is a **normal domain**, iff it satisfies the following two properties:

(1) R is an integral domain

(2) R is **normal**, that is: For any a, $b \in R$ with $a \neq 0$ we get: If there is some monic polynomial $f \in R[t]$ such that $f(b/a) = 0 \in \mathrm{QUOT}(R)$, then we already had $a \mid b$.

(2.66) Example: (viz. 1048)

(i) *UFDs need not be noetherian!* As an example regard a field $(E, +, \cdot)$, then the polynomial ring in countably many variables $E[t_i \mid i \in \mathbb{N}]$ is an UFD by the lemma of Gauss (7.29). But it is not noetherian (by the examples in section 2.4).

(ii) *Noetherian integral domains need not be UFDs!* As an example we would like to present the following algebraic number ring

$$\mathbb{Z}[\sqrt{-3}] \;:=\; \left\{ a + ib\sqrt{3} \mid a, b \in \mathbb{Z} \right\} \;\subseteq\; \mathbb{C}$$

It is quite easy to see that in this ring $2 \in \mathbb{Z}[\sqrt{-3}]$ is an irreducible element, that is not prime. Hence $\mathbb{Z}[\sqrt{-3}]$ cannot be an UFD. Never the less it is an integral domain (being a sub-ring of $\mathbb{C}$) and noetherian (by Hilbert's basis theorem (2.42), as it is generated by $\sqrt{-3}$ over $\mathbb{Z}$).

(iii) *Residue rings (even integral domains) of UFDs need not be UFDs!* As an example let us start with the polynomial ring $\mathbb{R}[s, t]$ in two variables over the reals. Then $\mathbb{R}[s, t]$ is an UFD by the lemma of Gauss (7.29). Now consider the residue ring

$$R \;:=\; \mathbb{R}[s,t] \Big/ \mathfrak{p} \quad \text{where} \quad \mathfrak{p} \;:=\; (s^2 + t^2 - 1)\mathbb{R}[s,t]$$

Then $p(s, t) = s^2 + t^2 - 1 \in \mathbb{R}[s, t]$ is an irreducible (hence prime) polynomial, such that $\mathfrak{p}$ is a prime ideal. Yet we are able to prove that R is not an UFD (in fact we will prove that there is an irreducible, non-prime element in a certain localization of R).

2.6 Euclidean Domains

For now we have studied the internal structure of rings. But if we take a look at polynomial ring (we have introduced the easiest, but most important case in (1.33)) we see that these feature the degree as an external function that neatly defines the structure of the ring. The most noteworthy property of polynomials is division with remainder. We already encountered this with the integers $\mathbb{Z}$, as well. In this case the external function is the absolute value. So it seems worthwhile to study these external functions and their impact on the ring's internal structure in general. As an instructive example let us stick to the polynomials first:

(2.67) Lemma: (viz. 747)
Let $(R, +, \cdot)$ be any commutative ring and fix a monic polynomial $f \in R[t]$ (i.e. $\mathrm{lc}(f) = 1$) over R. Then for any other polynomial $g \in R[t]$ there are q, $r \in R[t]$ such that the following two properties hold true

(1) $g = qf + r$

(2) $\deg(r) < \deg(f)$ or $r = 0$

If R is an integral domain, then these polynomials q and r are uniquely determined and it is customary to introduce two binary operations, to denote them

$$\begin{aligned} g \text{ div } f &:= q \\ g \text{ mod } f &:= r \end{aligned}$$

(2.68) Remark:
The proof of the above lemma even provides an algorithm (that we present in *pseudo-code* here) how to iteratively compute these polynomials q and r

input	$f \in R[t]$ monic,
	$g \in R[t]$
initialisation	$q \leftarrow 0$
	$r \leftarrow g$
	$m \leftarrow \deg(f)$
algorithm	while $r \neq 0$ and $\deg(r) \geq \deg(f)$ do begin
	$\quad n \leftarrow \deg(r)$
	$\quad p \leftarrow q + \mathrm{lc}(r)\, t^{n-m}$
	$\quad q \leftarrow q + p$
	$\quad r \leftarrow r - p \cdot f$
	end-while
output	q, r

Let us take the division with remainder property of polynomials as a pattern how to generally define what a division with remainder should provide. As an ingredient we need an external function $\nu = \deg$ that gives a criterion whether the remainder r is smaller than the dividend f.

(2.69) Definition:
Let $(R,+,\cdot)$ be an integral domain and ν be a mapping of the form $\nu : R \setminus \{0\} \to \mathbb{N}$. Then the ordered pair (R,ν) is said to be an **Euclidean domain**, iff R allows *division with remainder* - that is for any a and $b \in R$ with $a \neq 0$ there are q, $r \in R$ such that we get

(1) $b = qa + r$

(2) $\nu(r) < \nu(a)$ or $r = 0$

(2.70) Remark:

- In this general setting the division with remainder need *not* be unique. Even in case $R = \mathbb{Z}$ of the integers we have $7 = 3 \cdot 2 + 1$ but also $7 = 4 \cdot 2 - 1$. It does get uniquely determined once we impose the additional condition $r \geq 0$, as we have seen in (1.28). However we will sometimes want to address these elements q and $r \in R$, even if there is no deterministic function to do so. Hence q is said to be the *quotient* and r is said to be the *remainder* of this operation. And we occasionally dare to employ the following notation, even if it suggests a functional correspondence that does not exist in the general setting!

$$\begin{aligned} b \text{ div } a &:= q \\ b \text{ mod } a &:= r \end{aligned}$$

- We will employ a notational trick to eliminate the distinction of the case $r = 0$ in the definition above. To do this we pick up a symbol $-\infty$ and set $-\infty < n$ for any $n \in \mathbb{N}$. Then we extend ν to

$$\nu \; : \; R \to \mathbb{N} \cup \{-\infty\} \; : \; a \mapsto \begin{cases} \nu(a) \text{ if } a \neq 0 \\ -\infty \text{ if } a = 0 \end{cases}$$

 Thereby the property to allow division with remainder simply reads as: For any a, $b \in R$ with $a \neq 0$ there are q, $r \in R$ such that we get both of the properties

 (1) $b = qa + r$
 (2) $\nu(r) < \nu(a)$

- In an Euclidean domain (R,ν) any $a \in R$ that satisfies $\nu(a) = 0$ already is a unit $a \in R^*$ of R. The converse need not be true however. That is we have the inclusion (but not necessarily equality)

$$\{\, a \in R \mid \nu(a) = 0 \,\} \quad \subseteq \quad R^*$$

 Prob using division with remainder we find q, $r \in R$ such that $1 = qa + r$ and $\nu(r) < \nu(a) = 0$. But the latter means $\nu(r) = -\infty$ and hence $r = 0$. We are left with $1 = qa$ and hence $a \in R^*$.

(2.71) Example: (viz. 1050)

(i) If $(E,+,\cdot)$ is a field, then (E,ν) is an Euclidean domain under any function $\nu : E \setminus \{0\} \to \mathbb{N}$. Because for any $0 \neq a \in E$ and $b \in E$ we may let $q := ba^{-1}$ and $r := 0$.

(ii) The ring $\mathbb{Z}$ of integers is an Euclidean domain $(\mathbb{Z}, \alpha)$ under the (slightly modified) absolute value α as an Euclidean function

$$\alpha \ : \ \mathbb{Z} \to \mathbb{N} \cup \{ -\infty \} \ : \ a \mapsto \begin{cases} a \text{ if } a > 0 \\ -a \text{ if } a < 0 \\ -\infty \text{ if } a = 0 \end{cases}$$

In fact consider $1 \leq a \in \mathbb{Z}$ and any $b \in \mathbb{Z}$ then for $q := b \text{ div } a$ and $r := b \bmod a$ (see below for a definition) we have $b = aq + r$ and $0 \leq r < a$ (in particular $\alpha(r) < \alpha(a)$). And in case $a < 0$ we can choose q and r similarly to have division with remainder.

$$\begin{aligned} b \text{ div } a &:= \max\{ q \in \mathbb{Z} \mid aq \leq b \} \\ b \bmod a &:= b - (b \text{ div } a) \cdot a \end{aligned}$$

(iii) If $(E, +, \cdot)$ is a field then the polynomial ring $E[t]$ in one variable over E is an Euclidean domain $(E[t], \deg)$ under the *degree* function

$$\deg \ : \ E[t] \setminus \{0\} \ : \ f \mapsto \max\{ k \in \mathbb{N} \mid f[k] \neq 0 \}$$

This is true because of the division algorithm for polynomials - see (2.67). Note that the division algorithm can be applied, as any non-zero polynomial can be made monic, since E is a field. However $R[t]$ will not be a Euclidean ring, unless R is a field. Also, though the division algorithm for polynomials can be generalized to Buchberger's algorithm, it is *untrue* that the polynomial ring $E[t_1, \ldots, t_n]$ is an Euclidean domain (for $n \geq 2$) under some Euclidean function ν.

(iv) Consider any $d \in \mathbb{Z}$ that is not the square of another integer, that is $\sqrt{d} \notin \mathbb{Z}$. Then we consider the sub-ring of $\mathbb{C}$ generated by $\sqrt{d}$

$$\mathbb{Z}[\sqrt{d}] \ := \ \left\{ a + b\sqrt{d} \mid a, b \in \mathbb{Z} \right\} \ \subseteq \ \mathbb{C}$$

Then the representation $x = a + b\sqrt{d} \in \mathbb{Z}[\sqrt{d}]$ is unique (that is for any a, b, f and $g \in \mathbb{Z}$ we get $a + b\sqrt{d} = f + g\sqrt{d} \iff (a, b) = (f, g)$). And thereby we obtain a well-defined ring-automorphism on $\mathbb{Z}[\sqrt{d}]$ by virtue of $x = a + b\sqrt{d} \mapsto \overline{x} := a - b\sqrt{d}$. Now define

$$\nu \ : \ \mathbb{Z}[\sqrt{d}] \setminus \{0\} \to \mathbb{N} \ : \ x = a + b\sqrt{d} \mapsto |x\overline{x}| = |a^2 - db^2|$$

Then ν is multiplicative, that is $\nu(xy) = \nu(x)\nu(y)$ for any x, $y \in \mathbb{Z}[\sqrt{d}]$. And it is quite easy to see that the units of $\mathbb{Z}[\sqrt{d}]$ is given to be

$$\mathbb{Z}[\sqrt{d}]^* \ = \ \left\{ x \in \mathbb{Z}[\sqrt{d}] \ \middle| \ \nu(x) = 1 \right\}$$

We will prove that for $d \leq -3$ the ring $\mathbb{Z}[\sqrt{d}]$ will not be an UFD, as 2 is an irreducible element, that is not prime. Yet for $d \in \{-2, -1, 2, 3\}$, we find that $(\mathbb{Z}[\sqrt{d}], \nu)$ is an Euclidean domain.

(2.72) Proposition: (viz. 1052)
Let (R,ν) be an Euclidean domain and $0 \neq a, b \in R$ be two non-zero elements. Then a and b have a greatest common divisor $g \in R$ that can be computed by the following (so called *Euclidean*) *algorithm*

input	$0 \neq a, b \in R$
initialisation	if $\nu(a) \leq \nu(b)$
	then $(f \leftarrow a, g \leftarrow b)$
	else $(f \leftarrow b, g \leftarrow a)$
algorithm	while $f \neq 0$ do begin
	choose $q, r \in R$ with
	$(g = qf + r$ and $\nu(r) < \nu(f))$
	$g \leftarrow f, f \leftarrow r$
	end-while
output	g

That is given $0 \neq a, b \in R$ we start the above algorithm that returns $g \in R$ and for this g we get $g \in \gcd\{a,b\}$. If now g denotes the greatest common divisor $g \in \gcd\{a,b\}$ of a and b, then there are r and $s \in R$ such that $g = ra + sb$. And these r and s can be computed (along with g) using the following enhancement of the *Euclidean algorithm*

input	$0 \neq a, b \in R$
initialisation	if $\nu(a) \leq \nu(b)$
	then $(f_1 \leftarrow b, f_2 \leftarrow a)$
	else $(f_1 \leftarrow a, f_2 \leftarrow b)$
algorithm	$k \leftarrow 1$
	repeat
	$k \leftarrow k + 1$
	choose q_k and $f_{k+1} \in R$ with
	$(f_{k-1} = q_k f_k + f_{k+1}$
	and $\nu(f_{k+1}) < \nu(f_k))$
	until $f_{k+1} = 0$
	$n \leftarrow k, g \leftarrow f_n$
	$r_2 \leftarrow 1, s_2 \leftarrow 0$
	$r_3 \leftarrow -q_2, s_3 \leftarrow 1$
	for $k = 3$ to $n-1$ step 1 do begin
	$r_{k+1} \leftarrow r_{k-1} - q_k r_k$
	$s_{k+1} \leftarrow s_{k-1} - q_k s_k$
	end-for
	if $\nu(a) \leq \nu(b)$
	then $(r \leftarrow r_n, s \leftarrow s_n)$
	else $(r \leftarrow s_n, s \leftarrow r_n)$
output	g, r and s

(2.73) Remark: $(\diamondsuit)$
In the case of $R = \mathbb{Z}$ it is well-known, that the units of $\mathbb{Z}_a = \mathbb{Z}/a\mathbb{Z}$ are precisely those $b + a\mathbb{Z}$ that satisfy $\gcd(a, b) = \pm 1$. And thereby the enhanced Euclidean algorithm even provides an efficient way of finding the inverse of $b + a\mathbb{Z}$. Use the algorithm to obtain r and $s \in \mathbb{Z}$ such that $1 = g = ra + sb$, then $1 + a\mathbb{Z} = (bs + a\mathbb{Z}) = (b + a\mathbb{Z})(s + a\mathbb{Z})$. Hence $s + a\mathbb{Z}$ is the inverse of $b + a\mathbb{Z}$. This is not purely theoretic, this computation is part of the RSA algorithm.

(2.74) Remark:
Presented in pseudo-code (as we did here) the Euclidean algorithm may seem a little artificial, but the idea behind it is quite simple: Given a and $b \in R$ we first look for a greatest common divisor g of a and b. First we arrange a and b in ascending order, that is we let $\{ f_1, f_2 \} = \{ a, b \}$ such that $\nu(f_2) \leq \nu(f_1)$. Then we use division with remainder successively, denoting $q_k := f_{k-1} \text{ div } f_k$ and $f_{k+1} := f_{k-1} \bmod f_k$. That is the next f_{k+1} is the remainder under the division of f_{k-1} by f_k. Hence we get a sequel of equations

$$\begin{aligned} f_1 &= q_2 f_2 + f_3 \\ f_2 &= q_3 f_3 + f_4 \\ &\vdots \\ f_{n-2} &= q_{n-1} f_{n-1} + f_n \\ f_{n-1} &= q_n f_n + 0 \end{aligned}$$

The thing is that at some point $n \in \mathbb{N}$ we find the remainder $f_{n+1} = 0$, that is f_n divides f_{n-1}. Once we have arrived here $g := f_n$ is a greatest common divisor of a and b. In other words: The greatest common divisor of a and b is the last non-zero remainder f_n in this chain of divisions with remainder.
But the enhanced Euclidean algorithm yields even more: Some r and $s \in R$ such that $g = ra + sb$. And the idea to find these coefficients r and s is quite simple again: Solve the above equations for the respective remainders, that is we compute

$$\begin{aligned} f_3 &= f_1 - q_2 f_2 \\ f_4 &= f_2 - q_3 f_3 \\ f_5 &= f_3 - q_4 f_4 \\ &\vdots \\ f_n &= f_{n-2} - q_{n-1} f_{n-1} \end{aligned}$$

Then we may replace f_3 in the equation for f_4 using the equation beforehand. This results in the equation $f_4 = f_2 - q_3(f_1 - q_2 f_2) = (1 + q_2)f_2 - q_3 f_1$. Now f_3 and f_4 appear in the equation for f_5 again. Replacing both with the previous two equations we find $f_5 = (f_1 - q_2 f_2) - q_4((1 + q_2)f_2 - q_3 f_1) = (1 + q_3 q_4)f_1 - (q_2 + q_4 + q_2 q_4)f_2$. Continuing like this we finally arrive at some equation of the form $f_n = \square f_1 + \square f_2$. And as $g = f_n$ is the greatest common divisor and f_1 and f_2 are just a and b this is precisely what we sought.

All this can be summarized in the following table: Let us assume $v(a) \leq v(b)$ and recall the notation $b \text{ div } a := q$ and $b \text{ mod } a := r$ where q and $r \in R$ are some (not uniquely determined) elements such that $b = qa + r$ and $v(r) < v(a)$. Then we can compute a greates common divisor $g \in \gcd(a, b)$

k	f_{k-1}	f_k	f_{k+1}	q_k
2	b	a	$b \text{ mod } a$	$b \text{ div } a$
3	a	$b \text{ mod } a$	$*$	$*$
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$
k	f_{k-1}	f_k	$f_{k-1} \text{ mod } f_k$	$f_{k-1} \text{ div } f_k$
k+1	f_k	f_{k+1}	$f_k \text{ mod } f_{k+1}$	$f_k \text{ div } f_{k+1}$
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$
n-1	f_{n-2}	f_{n-1}	g	$*$
n	f_{n-1}	g	0	f_{n-1}/g

The expanded Euclidean algorithm appends this table by the columns r_k and s_k in order to compute the elements $r, s \in R$ such that $g = ra + sb$

k	q_k	r_k	s_k
2	$b \text{ div } a$	1	0
3	$*$	$-(b \text{ div } a)$	1
$\vdots$	$\vdots$	$\vdots$	$\vdots$
k	$f_{k-1} \text{ div } f_k$	$r_{k-2} - q_{k-1}r_{k-1}$	$s_{k-2} - q_{k-1}s_{k-1}$
k+1	$f_k \text{ div } f_{k+1}$	$r_{k-1} - q_k r_k$	$r_{k-1} - q_k r_k$
$\vdots$	$\vdots$	$\vdots$	$\vdots$
n	f_{n-1}/g	r	s

(2.75) Example:
As an application we want to compute the greatest common divisor of $a = 84$ and $b = 1330$ in $\mathbb{Z}$. That is we initialize the algorithm with $f_1 := b = 1330$ and $f_2 := a = 84$. Then we find $1330 = 15 \cdot 84 + 70$ (at $k = 2$), which is $q_2 = 15$ and $f_3 = 70$. Thus in the next step (now $k = 3$) we observe $84 = 1 \cdot 70 + 14$, that is we may choose $q_3 := 1$ and $f_4 := 14$. Now (at counter $k = 4$) we have $70 = 5 \cdot 14 + 0$ which means $q_4 = 5$ and $f_5 = 0$. Thus for $n := k = 4$ we have finally arrived at $f_{k+1} = 0$ terminating the first part of the algorithm. It returns $g = f_n = 14$ the greatest common divisor of $a = 84$ and $b = 1330$. The following table summarizes the computations

k	f_{k-1}	f_k	f_{k+1}	q_k
2	1330	84	70	15
3	84	70	14	1
4	70	14	0	5

Now in the second part of the algorithm we initialize $r_2 := 1$, $s_2 := 0$, $r_3 := -q_2 = -15$ and $s_3 := 1$. Then we compute $r_4 := r_2 - q_3 r_3 = 16$ and $s_4 := s_2 - q_3 s_3 = -1$. As $n = 4$ this already is $r = r_4 = 16$ and $s = s_4 = -1$. And in fact $ra + bs = 14 = g$. Again we summarize these computations in

k	q_k	r_k	s_k
2	15	1	0
3	1	-15	1
4	5	16	-1

(2.76) Proposition: (viz. 1053)
Consider an integral domain $(R,+,\cdot)$ and let $n \in \mathbb{N}$, then we recursively define a subset R_n of n-th level elements of R. The 0-th level elements are the units of R. The $(n+1)$-th level elements are those $a \in R$, that divide all $b \in R$ up to some n-th level element $r \in R_n$. Formally that is

$$\begin{aligned} R_0 &:= R^* = \{\, a \in R \mid \exists\, b \in R : ab = 1 \,\} \\ R_{n+1} &:= \{\, a \in R \setminus \{0\} \mid \forall\, b \in R\ \exists\, r \in R_n \cup \{0\} : a \mid b - r \,\} \end{aligned}$$

(i) The subsets $R_n \subseteq R$ form an ascending chain $R_0 \subseteq R_1 \subseteq \ldots \subseteq R_n \subseteq R_{n-1} \subseteq \ldots$

(ii) If (R,ν) is an Euclidean domain that for any $n \in \mathbb{N}$ the set of $a \in R$ with $a \neq 0$ and $\nu(a) \leq n$ is contained in R_n, formally that is the inclusion

$$\{\, a \in R \mid \nu(a) \leq n \,\} \subseteq R_n \cup \{0\}$$

(iii) Conversely if the R_n cover R, that is $R \setminus \{0\} = \bigcup_n R_n$, then (R,μ) becomes an Euclidean domain under the following Euclidean function

$$\mu : R \setminus \{0\} : a \mapsto \min\{\, n \in \mathbb{N} \mid a \in R_n \,\}$$

And thereby μ satisfies the following two statements for any $a, b \in R$ where $b \neq 0$

$$\mu(a) \leq \mu(ab)$$

$$\mu(b) = \mu(ab) \iff a \in R^*$$

(iv) In particular R is an Euclidean domain, if and only if these sets R_n cover $R \setminus \{0\}$. Put formally

$$R \setminus \{0\} = \bigcup_{n \in \mathbb{N}} R_n \iff \exists\, \nu : (R,\nu) \text{ Euclidean domain}$$

(v) If (R,ν) is an Euclidean domain, then (R,μ) is an Euclidean domain, too and for any $a \in R$ we get $\mu(a) \leq \nu(a)$. In this sense μ is the *minimal Euclidean function* on R.

2.7 Principal Ideal Domains

(2.77) Definition:
Let $(R,+,\cdot)$ be any commutative ring, then an ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is said to be **principal**, iff it can be generated by a single element, i.e. $\mathfrak{a} = aR$ for some $a \in R$. And R is said to be a **principal ring** iff every ideal of R is principal, that is iff

$$\forall\, \mathfrak{a} \trianglelefteq_{\mathrm{i}} R \;\; \exists\, a \in R \;\; : \;\; \mathfrak{a} = aR$$

Finally R is said to be a **principal ideal domain** (which we will always abbreviate by **PID**), iff it is an integral domain in which every ideal is generated by a single element:

(1) R is an integral domain and

(2) $\forall\, \mathfrak{a} \trianglelefteq_{\mathrm{i}} R\; \exists\, a \in R \;:\; \mathfrak{a} = aR$

(2.78) Remark:

- Clearly the trivial ideals $\mathfrak{a} = 0$ and $\mathfrak{a} = R$ always are principal, as they can be generated by the elements $0 = 0R$ and $R = 1R$ respectively.
- If R is a principal ring and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is any ideal, then the quotient ring $R/\mathfrak{a}$ is principal, too. Prob due to the correspondence theorem (1.66) any ideal $\mathfrak{u} \trianglelefteq_{\mathrm{i}} R/\mathfrak{a}$ is of the form $\mathfrak{u} = \mathfrak{b}/\mathfrak{a}$ for some ideal $\mathfrak{a} \subseteq \mathfrak{b} \trianglelefteq_{\mathrm{i}} R$. Thus there is some $b \in R$ with $\mathfrak{b} = bR$. Now let $u := b + \mathfrak{a}$, then clearly $\mathfrak{u} = \{\, bh + \mathfrak{a} \mid h \in R \,\} = u(R/\mathfrak{a})$ is a principal ideal, too.
- Let $R_1, \ldots, R_n$ be principal rings, then the direct sum $R_1 \oplus \cdots \oplus R_n$ is a principal ring, too. Prob by (1.97) the ideals of the direct sum are of the form $\mathfrak{a}_1 \oplus \cdots \oplus \mathfrak{a}_n$ for some ideals $\mathfrak{a}_i \trianglelefteq_{\mathrm{i}} R_i$. Thus by assumption there are some $a_i \in R_i$ such that $\mathfrak{a}_i = a_i R_i$. And thereby it is clear, that $\mathfrak{a}_1 \oplus \cdots \oplus \mathfrak{a}_n = (a_1, \ldots, a_n)R_1 \oplus \cdots \oplus R_n$ is principal again.

(2.79) Lemma: (viz. 1054)

(i) If $(R,+,\cdot)$ is a PID (in particular non-zero), then all non-zero prime ideals of R already are maximal, formally (in a fancier language this can be put as $\mathrm{kdim} R \leq 1$). That is

$$\mathrm{Spec}(R) \;\; = \;\; \mathrm{Smax}(R) \cup \{0\}$$

(ii) If $(R,+,\cdot)$ is a PID then R already is a noetherian ring and an UFD. That is any $0 \neq a \in R$ admits an (essentially uniqe) decomposition $a = \alpha p_1 \ldots p_k$ into prime elements p_i - viz. (2.60).

(iii) If (R,ν) is an Euclidean domain then R already is a PID. In fact if $0 \neq \mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is a non-zero ideal then $\mathfrak{a} = aR$ for any $a \in \mathfrak{a}$ satisfying

$$\nu(a) \;\; = \;\; \min\{\, \nu(b) \mid 0 \neq b \in \mathfrak{a} \,\}$$

(iv) If $(R,+,\cdot)$ is an integral domain such that any prime ideal is principal, then R already is a PID. Put formally that is the equivalence of the statements

$$R \text{ PID} \;\; \Longleftrightarrow \;\; \forall\, \mathfrak{p} \in \mathrm{Spec}(R) \;\; \exists\, p \in R \;:\; \mathfrak{p} = pR$$

(2.80) Proposition: (viz. 1055)
Let $(F,+,\cdot)$ be any (even a finite) field, then for any $1 \leq n \in \mathbb{N}$ the polynomial ring $F[t_1,\ldots,t_n]$ in finitely many variables over F has infinitely many maximal ideals. In terms of the sprectrum

$$\#\mathrm{Smax}\big(F[t_1,\ldots,t_n]\big) \;=\; \infty$$

(2.81) Remark:

- In (2.71.(i)) we have seen that any field E is an Euclidean domain (under any ν). Hence any field is a PID due to (iii) above. But this is also clear from the fact that the only ideals of a field E are 0 and E itself. And these are principal due to $0 = 0E$ and $E = 1E$. Also (i) is trivially satisfied: The one and only prime ideal of a field is 0.

- The items (i) and (ii) in the above lemma are very useful and will yield a multitude of corollaries (e.g. the lemma of Kronecker that gives birth to field theory). And (iii) provides one of the reasons why we have introduced Euclidean domains: Combining (iii) and (ii) we see that any Euclidean domain is an UFD. And this yields an elegant way of proving that a certain integral domain R is an UFD. Just establish an Euclidean function ν on R and voilà R is an UFD.

- Due to example (2.71.(ii)) we know that $(\mathbb{Z},\alpha)$ is an Euclidean domain. By (iii) above this means that $\mathbb{Z}$ is a PID and (ii) then implies that $\mathbb{Z}$ is an UFD. By definition of UFDs this means that $\mathbb{Z}$ allows essentially unique prime decomposition. This now is a classical result that is known as the *Fundamental Theorem of Arithmetic*. We have proved an even stronger version, namely

$$(R,\nu) \text{ Euclidean domain} \quad\Longrightarrow\quad R \text{ is an UFD}$$

- In the subsequent proposition we will discuss how far a PID deviates from being an Euclidean domain (though this is of little practical value). To do this we will introduce the notion of a Dedekind-Hasse norm. We will then see that an Euclidean function can be easily turned into a Dedekind-Hasse norm and that R is a PID if and only if it admits a Dedekind-Hasse norm. This of course is another way of proving that any Euclidean domain is a PID.

(2.82) Proposition: (viz. 1056)

(i) If $(R,+,\cdot)$ is a PID then R admits a multiplicative *Dedekind-Hasse* norm. That is there is a function $\delta : R \to \mathbb{N}$ satisfying the following three properties for any $a, b \in R$

(1) $\delta(ab) \;=\; \delta(a)\delta(b)$

(2) $\delta(a) = 0 \iff a = 0$

(3) if $a, b \neq 0$ then $b \in aR$ or $\exists\, r \in aR + bR$ such that $\delta(r) < \delta(a)$

Nota to be precise we may define $\delta(0) := 0$ and for any $0 \neq a \in R$ we let $\delta(a) := 2^k$ for $k := \ell(a)$ the length of any decomposition of $a = \alpha p_1 \ldots p_k$ into prime elements.

(ii) If $(R,+,\cdot)$ is an integral domain and δ is a Dedekind-Hasse norm on R (that is $\delta : R \to \mathbb{N}$ is a function satisfying (2) and (3) in (i)), then R already is a PID. In fact if $0 \neq \mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ is a non-zero ideal then we get $\mathfrak{a} = aR$ for any $0 \neq a \in \mathfrak{a}$ satisfying

$$\delta(a) \quad = \quad \min\{\, \delta(b) \mid 0 \neq b \in \mathfrak{a} \,\}$$

(iii) If (R,ν) is an Euclidean domain then we obtain a Dedekind-Hasse norm on R (that is $\delta : R \to \mathbb{N}$ satisfies (2) and (3) in (i)) by letting

$$\delta \;:\; R \to \mathbb{N} \;:\; a \mapsto \begin{cases} 0 \text{ if } a = 0 \\ \nu(a) + 1 \text{ if } a \neq 0 \end{cases}$$

(2.83) Lemma: (viz. 1056) **of Bezout**
Let $(R,+,\cdot)$ be an integral domain and $A \subseteq R$ be a non-empty $A \neq \emptyset$ subset of R. Then we obtain the following statements

(i) The intersection of the ideals aR (where $a \in A$) is a principal ideal if and only if A admits a least common multiple. More precisely for any $m \in R$ we obtain the following equivalence

$$\bigcap_{a \in A} aR = mR \quad \Longleftrightarrow \quad m \in \operatorname{lcm}(A)$$

(ii) If the sum of the ideals aR (where $a \in A$) is a principal ideal then A admits a greatest common divisor. More precisely for any $d \in R$ we obtain the following equivalence

$$\sum_{a \in A} aR = dR \quad \Longrightarrow \quad d \in \gcd(A)$$

Nota the converse implication is *untrue* in general. E.g. regard the polynomial ring $R = \mathbb{Z}[t]$, then $1 \in \gcd(2,t)$ but the ideal $2R + tR$ is not principal. The converse is true in PIDs however:

(iii) If R even is a PID then the sum of the ideals aR (where $a \in A$) is the principal ideal generated by the greatest common divisor of A. More precisely for any $d \in R$ we obtain the following equivalence

$$\sum_{a \in A} aR = dR \quad \Longleftrightarrow \quad d \in \gcd(A)$$

In particular in a PID a greatest common divisor $d \in \gcd(A)$ can be written as a linear combination of elements of $a \in A$, formally this is the property

$$\exists\, (b_a) \in R^{\oplus A} \;\; : \;\; d \;=\; \sum_{a \in A} a b_a$$

Nota in an Euclidean ring (R,ν) (supposed that A is finite) the Euclidean algorithm (2.72) provides an effective method to (recursively, using (2.64.(viii))) compute these elements b_a.

(iv) Let R be a PID again and consider finitely many non-zero elements $0 \neq a_1, \ldots, a_n \in R$ such that the a_i are pairwise relatively prime (that is $i \neq j \in 1 \ldots n \implies 1 \in \gcd(a_i, a_j)$). If now $b \in R$ then there are $b_1, \ldots, b_n \in R$ such that we obtain the equality (in the quotient field $\mathrm{QUOT}(R)$ of R)

$$\frac{b}{a_1 \ldots a_n} = \frac{b_1}{a_1} + \cdots + \frac{b_n}{a_n}$$

In an UFD R any collection $A \subseteq R$, $A \neq \emptyset$ of elements of R has a greatest common divisor d, due to (2.64.(v)). And we have just seen that in a PID the greatest common divisor d, that can even be written as a linear combination $d = \sum_a ab_a$. In an Euclidean domain d and the b_a can even be computed algorithmically, using the Euclidean algorithm. We now ask for the converse, that is: If any finite collection of elements of R has a greatest common divisor, that is a linear combination of the collection, can we then conclude that R a PID already? The answer will be *yes* for noetherian rings, but *no* in general.

(2.84) Definition: (viz. 1057)
Let $(R, +, \cdot)$ be an integral domain, then R is said do be a **Bezout domain** iff it satisfies one of the following three equivalent properties

(a) Any two elements a, $b \in R$ admit a greatest common divisor, that can be written as a linear combination of a and b. Formally that is

$$\forall\, a, b \in R \;\; \exists\, r, s \in R \;\; : \;\; ra + sb \in \gcd\{a, b\}$$

(b) For any a, $b \in R$ the ideal $aR + bR$ is principal, that is there is some $d \in R$ such that we get $dR = aR + bR$. Formally again that is

$$\forall\, a, b \in R \;\; \exists\, d \in R \;\; : \;\; dR = aR + bR$$

(c) Any finitely generated ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ of R is principal. We write this as a formal implication again:

$$\forall\, \mathfrak{a} \trianglelefteq_{\mathrm{i}} R \;\; : \;\; \mathfrak{a} \text{ finitely generated} \implies \mathfrak{a} \text{ principal}$$

(2.85) Corollary: (viz. 1058)
Let $(R, +, \cdot)$ be any ring ring, then the following statements are equivalent

(a) R is a PID

(b) R is an UFD and Bezout domain

(c) R is a noetherian ring and Bezout domain

(2.86) Example:

(i) Let $R := \mathbb{Z} + t\mathbb{Q}[t] := \{f \in \mathbb{Q}[t] \mid f(0) \in \mathbb{Z}\} \subseteq \mathbb{Q}[t]$ be the sub-ring of polynomials over $\mathbb{Q}$ with constant term in $\mathbb{Z}$. Then R is an integral domain, as it is a sub-ring of $\mathbb{Q}[t]$. And the units units of R are $R^* = \{-1, 1\}$ only, as $fg = 1$ implies both $f(0)g(0) = 1$ and $\deg(f) = 0 = \deg(g)$. However R neither is noetherian, nor an UFD, as it contains the following infinitely ascending chain of principal ideals

$$tR \subset \frac{1}{2}tR \subset \ldots \subset \frac{1}{2^n}tR \subset \frac{1}{2^{n+1}}tR \subset \ldots$$

[the inclusion is strict, as 2 is not a unit of R]. (Also the ideal $t\mathbb{Q}[t] \trianglelefteq_{\mathrm{i}} R$ is not finitely generated, as else there would be some $a \in \mathbb{Z}$ such that $at\mathbb{Q}[t] \subseteq t\mathbb{Z}[t]$, which is absurd). Yet it can be proved that R is a Bezout domain (see [Dummit, Foote, 9.3, exercise 5] for hints on this).

(ii) We want to present another example of a Bezout domain: Fix any field $(E, +, \cdot)$ and let S be the polynomial ring in countably many variables $S := E[t_k \mid k \in \mathbb{N}]$. Let us denote the ideal

$$\mathfrak{u} := \langle t_k - t_{k+1}^2 \mid k \in \mathbb{N} \rangle_{\mathrm{i}} \trianglelefteq_{\mathrm{i}} S$$

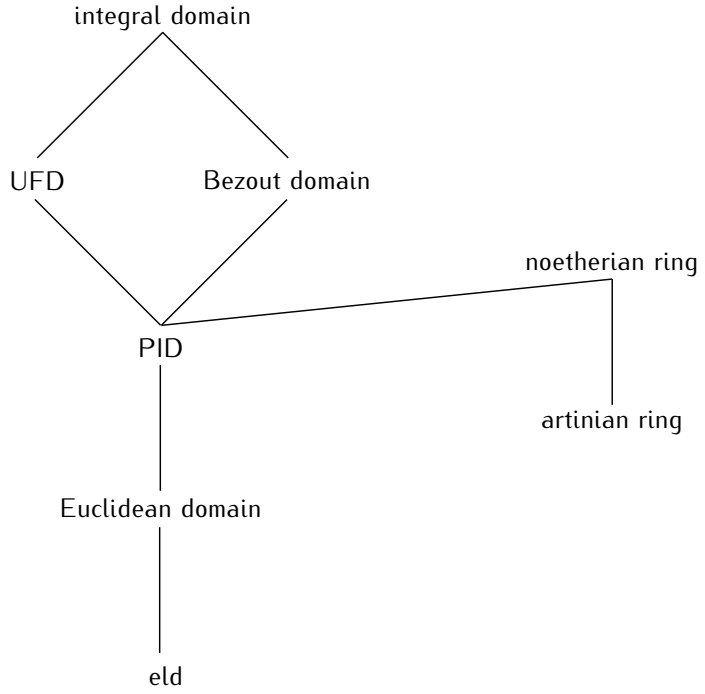
Then $R := S/\mathfrak{u}$ is a Bezout domain (refer to [Dummit, Foote, 9.2, exercise 12] for hints). However it is no noetherian ring (in particular no PID), as the following ideal $\mathfrak{a}$ of R is *not* finitely generated

$$\mathfrak{a} := \langle t_k + \mathfrak{u} \mid k \in \mathbb{N} \rangle_{\mathrm{i}} \trianglelefteq_{\mathrm{i}} R$$

(iii) ($\diamondsuit$) Let us denote denote the integral closure of $\mathbb{Z}$ in $\mathbb{C}$ by $\mathcal{O}$: To stay self-contained: Let us denote $\mathbb{Z}[t]_1 := \{t^n + a_1 t^{n-1} + \cdots + a_n \in \mathbb{Z}[t] \mid n \in \mathbb{N},\ a_i \in \mathbb{Z}\}$) the set of monic polynomials over $\mathbb{Z}$, then $\mathcal{O}$ is the set of $z \in \mathbb{C}$ that satisfy an equation of the form $f(z) = 0$ for some $f \in \mathbb{Z}[t]_1$

$$\mathcal{O} := \{z \in \mathbb{C} \mid \exists f \in \mathbb{Z}[t]_1 : f(z) = 0\}$$

E.g. $\sqrt{2} \in \mathcal{O}$, as $\sqrt{2}$ satisfies the equation $t^2 - 1$, but $1/2 \notin \mathcal{O}$, as this would require $2t - 1$ to be a factor of the equation. The integral closure always is a sub-ring (and in particular an integral domain, as $\mathbb{C}$ is a field). In fact $\mathcal{O}$ is a Bezout domain that satisfies $\mathrm{Spec}(\mathcal{O}) = \mathrm{Smax}(\mathcal{O}) \cup \{0\}$ (see [Dummit, Foote, chapter 16.3, exercise 23] for hints on how to prove this). However $\mathcal{O}$ neither is noetherian, nor an UFD, as it contains the following infinitely ascending chain of principal ideals



$$2\mathcal{O} \subset \sqrt{2}\mathcal{O} \subset \sqrt[4]{2}\mathcal{O} \subset \ldots \subset \sqrt[2^n]{2}\mathcal{O} \subset \sqrt[2^{n+1}]{2}\mathcal{O} \subset \ldots$$

(iv) Consider $\omega := (1 + i\sqrt{19})/2 \in \mathbb{C}$ and consider the following sub-ring $\mathbb{Z}[\omega] := \{a + b\omega \mid a, b \in \mathbb{Z}\}$ of $\mathbb{C}$. Then we obtain a Dedekind-Hasse norm on $\mathbb{Z}[\omega]$ by letting

$$\delta : \mathbb{Z}[\omega] \to \mathbb{N} : a + b\omega \mapsto a^2 + ab + 5b^2$$

(this is proved in [Dummit, Foote, page 282]). In particular $\mathbb{Z}[\omega]$ is a PID by virtue of (2.82.(ii)). However $\mathbb{Z}[\omega]$ is *not* an Euclidean domain (under any function ν whatsoever). The latter statement is proved in [Dummit, Foote, page 277].

(2.87) Remark:
By now we have studied a quite respectable list of different kinds of commutative rings from integral domains and fields over noetherian rings to Bezout domains. Thereby we have found several inclusions, that we wish to summarize in the diagram below:

Note however that every single inclusion in this diagram is strict. E.g. there are integral domains that are not Bezout domains and there are PIDs that are not Euclidean domains. The following table presents examples of rings R that satisfy one property, but not the next stronger one

R	is	is not
$\mathbb{Z}[\sqrt{-3}]$	noetherian integral domain	UFD
$\mathbb{Z}+t\mathbb{Q}[t]$	Bezout domain	noetherian, UFD
$\mathbb{Q}[s,t]$	noetherian UFD	Bezout domain
$\mathbb{Z}[(1+\sqrt{-19})/2]$	PID	Euclidean domain
$\mathbb{Z}$	Euclidean domain	field, artinian ring

2.8 Lasker-Noether Decomposition

Primary decomposition is a very strong property and as such something that is not satisfied often. Historically ideals have been introduced by Richard Dedekind to be ideal numbers, that are better behaved, than the elements of the algebraic number fields themselves. For example take a look at the following ring

$$\mathbb{Z}[\sqrt{-5}] \;:=\; \mathbb{Z}[t] \Big/ (t^2+5)\mathbb{Z}[t]$$

The element $x := t + (t^2+5)\mathbb{Z}[t]$ satisfies $x^2 + 5 = 0$ and is hence denoted as $\sqrt{-5} := x$. An isomorphic realization of this ring is the sub-ring of $\mathbb{C}$ generated by the single element $x := 5i \in \mathbb{C}$. This element can be used to present two primary decompositions of 6 that are *not* essentially equal:

$$6 \;=\; 2 \cdot 3 \;=\; \left(1-\sqrt{-5}\right)\left(1+\sqrt{-5}\right)$$

Remember that according to (2.59) in a noetherian integral domain we always have a decomposition of an element into irreducible elements - problem is that this decomposition is far from unique. That is the reason why we had to regard prime elements instead. In this section we will try to remedy this by decomposing whole ideals instead of elements of a noetherian ring.

It turns out that this decomposition of ideals is closely related to decomposing geometric objects (varieties) into smaller parts. That also is the application where the notions of *isolated* and *embedded* components come from (which will be introduced, later on). But this has to be left for a course in algebraic geometry.

Note that the noetherian and factorial properties are completely independent of one and another: E.g. $\mathbb{Z}[\sqrt{-5}]$ is noetherian, but not factorial, whereas $\mathbb{Z}[t_i \mid i \in \mathbb{N}]$ is factorial, but not noetherian. But we will see, that in case of noetherian UFDs both theories coincide.

In order to begin by defining the basic notion of a primary ideal, we will use the set $\mathrm{ZD}(R)$ of *zero-divisors* and the *nil-radical* $\mathrm{NIL}(R)$ of a ring R and the set $\mathrm{ZD}_R(M)$ of *zero-divisors* of an R-module M. This has not been introduced yet, but we will only use it in the case $M = R/\mathfrak{a}$. Also we give a survey of these notions in the remark following the definition.

In the definition to come, we will see, that a primary ideal is similar to a prime ideal, but somewhat weaker: If a product ab is contained in the primary ideal $\mathfrak{a}$ then only one of them needs to be contained in $\mathfrak{a}$, the other may belong to the radical $\sqrt{\mathfrak{a}}$ only:

(2.88) Definition: (viz. 1058)
Let $(R, +, \cdot)$ be a commutative ring and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be a proper (i.e. $\mathfrak{a} \neq R$) ideal of R. Then $\mathfrak{a}$ is said to be a **primary** ideal of R, iff it satisfies one of the following equivalent conditions

(a) The radical of $\mathfrak{a}$ contains the set of zero-divisors of $R/\mathfrak{a}$ (as an R-module)

$$\mathrm{ZD}_R\left(R \Big/ \mathfrak{a}\right) \;\subseteq\; \sqrt{\mathfrak{a}}$$

(b) In the ring $R/\mathfrak{a}$ the set of zero-divisors is contained in the nil radical

$$\mathrm{ZD}\left(R \Big/ \mathfrak{a}\right) \;\subseteq\; \mathrm{NIL}\left(R \Big/ \mathfrak{a}\right)$$

(c) The set of zero-divisors of $R/\mathfrak{a}$ (as a ring) equals the nil-radical of $R/\mathfrak{a}$

$$\text{ZD}\left(R\Big/\mathfrak{a}\right) \;=\; \text{NIL}\left(R\Big/\mathfrak{a}\right)$$

(d) For any two elements $a, b \in R$ of R we obtain the following implication

$$ab \in \mathfrak{a},\ b \notin \mathfrak{a} \quad\Longrightarrow\quad a \in \sqrt{\mathfrak{a}}$$

(e) For any two elements $a, b \in R$ of R we obtain the following implication

$$ab \in \mathfrak{a},\ b \notin \sqrt{\mathfrak{a}} \quad\Longrightarrow\quad a \in \mathfrak{a}$$

And if $\mathfrak{a}$ is a primary ideal, then it is customary to say that $\mathfrak{a}$ is **associated** to (the prime ideal) $\sqrt{\mathfrak{a}}$. Finally the set of all primary ideals of R is said to be the **primary spectrum** of R and we will abbreviate this by $\text{Spri}(R)$. And if $\mathfrak{p} \in \text{Spec}(R)$ is a prime ideal of R, then we denote the set of all primary ideals of R associated to $\mathfrak{p}$, by $\text{Spri}_{\mathfrak{p}}(R)$

$$\begin{aligned}\text{Spri}(R) &:= \{\,\mathfrak{a} \trianglelefteq_{\text{i}} R \mid \mathfrak{a} \neq R,\ (\text{a})\,\}\\ \text{Spri}_{\mathfrak{p}}(R) &:= \left\{\,\mathfrak{a} \in \text{Spri}(R) \;\middle|\; \sqrt{\mathfrak{a}} = \mathfrak{p}\,\right\}\end{aligned}$$

Nota clearly associateness is an equivalence relation on $\text{Spri}(R)$. That is for any primary ideals $\mathfrak{a}$ and $\mathfrak{b} \trianglelefteq_{\text{i}} R$ we let $\mathfrak{a} \approx \mathfrak{b} :\Longleftrightarrow \sqrt{\mathfrak{a}} = \sqrt{\mathfrak{b}}$ and thereby $\approx$ is an equivalence relation on $\text{Spri}(R)$. Further if $\mathfrak{p} = \sqrt{\mathfrak{a}}$, then $\text{Spri}_{\mathfrak{p}}(R)$ is precisely the equivalence class of $\mathfrak{a}$ under $\approx$.

(2.89) Remark:
In the definition above there already appeared the notion of zero-divisors of a module (which will be introduced in 3.2). Thus we wish to shortly present what this means in the context here. Let $(R, +, \cdot)$ be a commutative ring and $\mathfrak{a} \trianglelefteq_{\text{i}} R$ be an ideal [and M be an R-module]. Then the set of *zero-divisors* of $M = R/\mathfrak{a}$ as an R-module will be defined to be

$$\begin{aligned}\text{ZD}_R(M) &= \{\,a \in R \mid x \in M\ :\ x \neq 0 \text{ and } ax = 0\,\}\\ \text{ZD}_R\left(R\Big/\mathfrak{a}\right) &= \left\{\,a \in R \;\middle|\; \exists\, b+\mathfrak{a} \in R\Big/\mathfrak{a}\ :\ b+\mathfrak{a} \neq 0+\mathfrak{a} \text{ and } a(b+\mathfrak{a}) = 0\,\right\}\\ &= \left\{\,a \in R \;\middle|\; \exists\, b+\mathfrak{a} \in R\Big/\mathfrak{a}\ :\ b \notin \mathfrak{a} \text{ and } ab \in \mathfrak{a}\,\right\}\end{aligned}$$

as $b + \mathfrak{a} = 0 + \mathfrak{a}$ is equivalent to $b \in \mathfrak{a}$ [by construction of $R/\mathfrak{a}$] and because of the identity $a(b+\mathfrak{a}) = ab + \mathfrak{a} = (a+\mathfrak{a})(b+\mathfrak{a})$ [which is just the definition of the scalar multiplication of $R/\mathfrak{a}$ as an R-module, resp. of the multiplication in the ring $R/\mathfrak{a}$]. Now take a look at the set of zero-divisors of $R/\mathfrak{a}$ as a ring

$$\begin{aligned}\text{ZD}\left(R\Big/\mathfrak{a}\right) &= \left\{\,a+\mathfrak{a} \in R\Big/\mathfrak{a} \;\middle|\; \exists\, b+\mathfrak{a} \in R\Big/\mathfrak{a}\ :\ b+\mathfrak{a} \neq 0+\mathfrak{a} \text{ and } (a+\mathfrak{a})(b+\mathfrak{a}) = 0\,\right\}\\ &= \left\{\,a+\mathfrak{a} \in R\Big/\mathfrak{a} \;\middle|\; \exists\, b+\mathfrak{a} \in R\Big/\mathfrak{a}\ :\ b \notin \mathfrak{a} \text{ and } ab \in \mathfrak{a}\,\right\}\end{aligned}$$

We find that the condition $b \notin \mathfrak{a}$ and $ab \in \mathfrak{a}$ in both of these sets coincides. From this we find, that $a \in \mathrm{zd}_R(R/\mathfrak{a})$ is equivalent to $a + \mathfrak{a} \in \mathrm{zd}(R/\mathfrak{a})$. In a more compact notation, this can be put as

$$\mathrm{zd}\left(R\Big/\mathfrak{a}\right) \;=\; \mathrm{zd}_R(R/\mathfrak{a})\Big/\mathfrak{a}$$

(2.90) Proposition: (viz. 1059)
Let $(R,+,\cdot)$ be a commutative ring and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be an ideal. Then we the following statements are true

(i) Any prime ideal of R already is primary. That is we obtain the following inclusion of the spectra

$$\mathrm{Spec}(R) \;\subseteq\; \mathrm{Spri}(R)$$

(ii) If $\mathfrak{a}$ is a primary ideal of R, then the radical $\sqrt{\mathfrak{a}}$ is a prime ideal of R. In fact it is the uniquely determined, smallest prime ideal containing $\mathfrak{a}$, that is we obtain the following implications

$$\mathfrak{a} \in \mathrm{Spri}(R) \;\Longrightarrow\; \sqrt{\mathfrak{a}} \in \mathrm{Spec}(R)$$

$$\mathfrak{a} \in \mathrm{Spri}(R) \;\Longrightarrow\; \left\{\sqrt{\mathfrak{a}}\right\} = \{\,\mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p}\,\}_*$$

(iii) If $\mathfrak{m} := \sqrt{\mathfrak{a}}$ is a maximal ideal of R, then $\mathfrak{a}$ is a primary ideal of R associated to $\mathfrak{m}$. Put formally

$$\sqrt{\mathfrak{a}} \in \mathrm{Smax}(R) \;\Longrightarrow\; \mathfrak{a} \in \mathrm{Spri}(R)$$

(iv) Suppose that $\mathfrak{m} \in \mathrm{Smax}(R)$ is a maximal ideal of R, such that there is some $k \in \mathbb{N}$ such that $\mathfrak{m}^k \subseteq \mathfrak{a} \subseteq \mathfrak{m}$. Then $\mathfrak{a}$ is a primary ideal of R associated to $\mathfrak{m}$. That is we obtain the implication

$$\mathfrak{m}^k \subseteq \mathfrak{a} \subseteq \mathfrak{m} \;\Longrightarrow\; \mathfrak{a} \in \mathrm{Spri}_{\mathfrak{m}}(R)$$

(v) If $\mathfrak{a}_1, \ldots, \mathfrak{a}_k \trianglelefteq_{\mathrm{i}} R$ are finitely many primary ideals of R, all associated to the same pirme ideal $\mathfrak{p} = \sqrt{\mathfrak{a}_i}$. Then their intersection is a primary ideal associated to $\mathfrak{p}$, too

$$\{\,\mathfrak{a}_1, \ldots, \mathfrak{a}_k\,\} \subseteq \mathrm{Spri}_{\mathfrak{p}}(R) \;\Longrightarrow\; \bigcap_{i=1}^{k} \mathfrak{a}_i \in \mathrm{Spri}_{\mathfrak{p}}(R)$$

(vi) If $u \in R$ and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is a primary ideal, with $\mathfrak{p} := \sqrt{\mathfrak{a}}$, then we get the following statements concerning the ideal $\mathfrak{a} : u = \{\, a \in R \mid au \in \mathfrak{a}\,\}$

(1) if $u \in \mathfrak{a}$ then $\mathfrak{a} : u = R$

(2) if $u \notin \mathfrak{a}$ then $\mathfrak{a} : u \in \mathrm{Spri}_{\mathfrak{p}}(R)$

(3) if $u \notin \mathfrak{p}$ then $\mathfrak{a} : u = \mathfrak{a}$

(vii) Consider a homomorphism $\varphi : R \to S$ between the commutative rings $(R,+,\cdot)$ and $(S,+,\cdot)$. If now $\mathfrak{b} \trianglelefteq_{\mathrm{i}} S$ is a primary ideal of S, then $\mathfrak{a} := \varphi^{-1}(\mathfrak{b})$ is a primary ideal of R. And if $\mathfrak{q} := \sqrt{\mathfrak{b}}$ denotes the ideal $\mathfrak{b}$ is associated to, then $\mathfrak{a}$ is associated to $\varphi^{-1}(\mathfrak{q})$. Formally that is

$$\mathfrak{b} \in \mathrm{Spri}_{\mathfrak{q}}(S) \;\Longrightarrow\; \varphi^{-1}(\mathfrak{b}) \in \mathrm{Spri}_{\varphi^{-1}(\mathfrak{q})}(R)$$

(viii) ($\diamondsuit$) Let $U \subseteq R$ be a multiplicatively closed set, $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ be a prime ideal of R with $\mathfrak{p} \cap U = \emptyset$ and denote by $\mathfrak{q} := U^{-1}\mathfrak{p} \trianglelefteq_{\mathrm{i}} U^{-1}R$ the corresponding prme ideal of $U^{-1}R$. Then we obtain a one-to-one correspondence, by

$$\begin{array}{rcl} \mathrm{Spri}_{\mathfrak{p}}(R) & \longleftrightarrow & \mathrm{Spri}_{\mathfrak{q}}(U^{-1}R) \\ \mathfrak{a} & \mapsto & U^{-1}\mathfrak{a} \\ \mathfrak{b} \cap R & \hookleftarrow & \mathfrak{b} \end{array}$$

(2.91) Example: (viz. 1060)

(i) Let $(R, +, \cdot)$ be an integral domain and $p \in R$ be a prime element of R. Then for any $1 \leq n \in \mathbb{N}$ the ideal $\mathfrak{a} := p^n R$ is primary and associated, to the prime ideal $\sqrt{\mathfrak{a}} = pR$.

(ii) In a PID $(R, +, \cdot)$ the primary ideals are precisely the ideals 0 and $p^n R$ for some $p \in R$ prime. Formally that is the identity

$$\mathrm{Spri}(R) \;=\; \{\, p^n R \mid 1 \leq n \in \mathbb{N},\ p \in R \text{ prime} \,\} \cup \{0\}$$

(iii) Primary ideals do *not* need to be powers of prime ideals. As an example let $(E, +, \cdot)$ be any field and consider $R := E[s,t]$. Then the ideal $\mathfrak{a} := \langle s, t^2 \rangle_{\mathrm{i}}$ is primary and associated to the maximal ideal $\mathfrak{m} := \langle s, t \rangle_{\mathrm{i}}$. In fact we get $\mathfrak{m}^2 \subset \mathfrak{a} \subset \mathfrak{m}$ and hence there is *no* prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ such that $\mathfrak{a} = \mathfrak{p}^k$ for some $k \in \mathbb{N}$.

(iv) Powers of prime ideals do *not* need to be primary ideals. As an example let $(E, +, \cdot)$ be any field again and consider $R := E[s,t,u]/\mathfrak{u}$ where $\mathfrak{u} := \langle u^2 - st \rangle_{\mathrm{i}}$. Let us denote $a := s + \mathfrak{u}$, $b := t + \mathfrak{u}$ and $c := u + \mathfrak{u}$. Then we obtain a prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ by letting $\mathfrak{p} := \langle b, c \rangle_{\mathrm{i}}$. However we will see that $\mathfrak{a} := \mathfrak{p}^2$ is no primary ideal.

(2.92) Proposition: (viz. 1061)
Let $(R, +, \cdot)$ be a commutative ring and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be a proper ideal of R, i.e. $\mathfrak{a} \neq R$. For any $n \in \mathbb{N}$ we define the n-th *symbolic power* $\mathfrak{a}^{(n)}$ of $\mathfrak{a}$ to be the following subset of R:

$$\mathfrak{a}^{(n)} \;:=\; \{\, a \in R \mid \exists\, u \in R \setminus \mathfrak{a} : au \in \mathfrak{a}^n \,\}$$

If $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ is a prime ideal of R and $n \geq 1$, then the n-th symbolic power of $\mathfrak{p}$ is an ideal of R, that contains $\mathfrak{p}^n$ and that satisfies some further properties, namely

(i) $\mathfrak{p}^n \subseteq \mathfrak{p}^{(n)} \subseteq \mathfrak{p}$

(ii) $\forall\, n \in \mathbb{N}$ we get $\mathfrak{p}^{(n+1)} \subseteq \mathfrak{p}^{(n)}$

(iii) $\mathfrak{p}^{(n)}$ is a primary ideal, with $\sqrt{\mathfrak{p}^{(n)}} = \mathfrak{p}$

(iv) Recall the notion of the ideal $\mathfrak{a}R_{\mathfrak{p}} = \{\, a/u \in R_{\mathfrak{p}} \mid a \in \mathfrak{a}, u \in R \setminus \mathfrak{p} \,\}$ in the localisation $R_{\mathfrak{p}}$, then

$$\mathfrak{p}^{(n)} R_{\mathfrak{p}} \;=\; \mathfrak{p}^n R_{\mathfrak{p}}$$

(2.93) Definition:
Let $(R,+,\cdot)$ be a commutative ring, then a proper ideal $\mathfrak{p}$ is said to be **irreducible** iff it is not the intersection of finitely many larger ideals. That is iff $\mathfrak{p}$ satisfies the following three properties

(1) $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ is an ideal

(2) $\mathfrak{p} \neq R$ is proper

(3) for any $\mathfrak{a}, \mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ we have $\mathfrak{p} = \mathfrak{a} \cap \mathfrak{b} \implies \mathfrak{p} = \mathfrak{a}$ or $\mathfrak{p} = \mathfrak{b}$

(2.94) Theorem: (viz. 1062)

(i) Let $(R,+,\cdot)$ be a commutative ring, then any prime ideal of R already is irreducible. That is for any ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ we get the implication

$$\mathfrak{p} \text{ prime} \implies \mathfrak{p} \text{ irreducible}$$

(ii) Let $(R,+,\cdot)$ be a noetherian ring, then any irreducible ideal of R already is primary. That is for any ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ we get the implication

$$\mathfrak{p} \text{ irreducible} \implies \mathfrak{p} \text{ primary}$$

(iii) Let $(R,+,\cdot)$ be a noetherian ring, then any proper ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$, $\mathfrak{a} \neq R$ admits an irreducible decomposition $(\mathfrak{p}_1,\ldots,\mathfrak{p}_k)$: There are ideals $\mathfrak{p}_i \trianglelefteq_{\mathrm{i}} R$ (where $i \in 1\ldots k$ and $1 \leq k \in \mathbb{N}$) such that

(1) $\forall\, i \in 1\ldots k \,:\, \mathfrak{p}_i$ is an irreducible ideal

(2) $\mathfrak{a} = \mathfrak{p}_1 \cap \cdots \cap \mathfrak{p}_k$

(2.95) Definition:
Let $(R,+,\cdot)$ be a commutative ring and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be an ideal of R. Then a tupel $\mathcal{A} = (\mathfrak{a}_1,\ldots,\mathfrak{a}_k)$ is said to be a **primary decomposition** of $\mathfrak{a}$, iff it satisfies both of the properties

(1) $\forall\, i \in 1\ldots k \,:\, \mathfrak{a}_i \in \mathrm{Spri}(R)$ is a primary ideal of R

(2) $\mathfrak{a} = \mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_k$

And $(\mathfrak{a}_1,\ldots,\mathfrak{a}_k)$ is said to be **minimal** (or **irredundant**) iff we further get the following two properties

(3) $\forall\, j \in 1\ldots k \,:\, \mathfrak{a} \neq \bigcap_{i\neq j} \mathfrak{a}_i$

(4) $\forall\, i \neq j \in 1\ldots k \,:\, \sqrt{\mathfrak{a}_i} \neq \sqrt{\mathfrak{a}_j}$

Finally if $\mathcal{A} = (\mathfrak{a}_1,\ldots,\mathfrak{a}_k)$ is a minimal primary decomposition of $\mathfrak{a}$, then let us denote $\mathfrak{p}_i := \sqrt{\mathfrak{a}_i}$. These ideals are called the *associated prime ideals* of $\mathfrak{a}$. Those $\mathfrak{a}_i$ that belong to minimal $\mathfrak{p}_i$ are known as *isolated components*. Those $\mathfrak{a}_i$ that are not isolated components, are said to be *embedded components*:

$$\begin{aligned} \mathrm{ass}(\mathcal{A}) &:= \{\, \mathfrak{p}_1,\ldots,\mathfrak{p}_k \,\} \\ \mathrm{iso}(\mathcal{A}) &:= \{\, \mathfrak{a}_i \mid i \in 1\ldots k,\ \mathfrak{p}_i \in \mathrm{ass}(\mathcal{A})_* \,\} \end{aligned}$$

$$\begin{aligned} &= \left\{ \mathfrak{a}_i \;\middle|\; i \in 1\ldots k,\ \forall j \in 1\ldots k : \mathfrak{p}_j \subseteq \mathfrak{p}_i \implies j = i \right\} \\ \operatorname{emb}(\mathcal{A}) &:= \{\, \mathfrak{a}_1, \ldots, \mathfrak{a}_k \,\} \setminus \operatorname{iso}(\mathcal{A}) \end{aligned}$$

(2.96) Example:
Let $(R, +, \cdot)$ be an UFD and $a \in R$ with $0 \neq a \notin R^*$. Then we pick up a primary decomposition of a, that is $a = p_1^{n_1} \ldots p_k^{n_k}$ where $1 \leq k \in \mathbb{N}$ and for any $i, j \in 1\ldots k$ we have $p_i \in R$ is prime, $1 \leq n_i \in \mathbb{N}$ and $p_i R = p_j R$ implies $i = j$. Then we obtain a minimal primary decomposition of $\mathfrak{a} = aR$

$$(\mathfrak{a}_1, \ldots, \mathfrak{a}_k) \quad \text{where} \quad \mathfrak{a}_i := p_i^{n_i} R$$

And for this primary decomposition we find $\mathfrak{p}_i := \sqrt{\mathfrak{a}_i} = p_i R$ and hence no embedded components, but

$$\begin{aligned} \operatorname{ass}(\mathfrak{a}_1, \ldots, \mathfrak{a}_k) &= \{\, \mathfrak{p}_1, \ldots, \mathfrak{p}_k \,\} \\ \operatorname{iso}(\mathfrak{a}_1, \ldots, \mathfrak{a}_k) &= \{\, \mathfrak{a}_1, \ldots, \mathfrak{a}_k \,\} \end{aligned}$$

(2.97) Remark:
So why would we call an intersection $\mathfrak{a} = \mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_k$ a *decomposition* of $\mathfrak{a}$? As in fact we think of a decomposition of $R/\mathfrak{a}$. Clearly, if $\mathfrak{a} = \mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_k$ then we find an injective homomorphism of rings

$$R \Big/ \mathfrak{a} \hookrightarrow \bigoplus_{i=1}^{k} R \Big/ \mathfrak{a}_i \ : \ b + \mathfrak{a} \mapsto (b + \mathfrak{a}_1, \ldots, b + \mathfrak{a}_k)$$

Prob the well-definedness is due to $\mathfrak{a} \subseteq \mathfrak{a}_i$ and (1.75) and the homomorphism properties are clear. And if $(b + \mathfrak{a}_i) = (c + \mathfrak{a}_i)$ then $b - c \in \mathfrak{a}_i$ for any $i \in 1\ldots k$ such that $b - c \in \mathfrak{a}$, which is $b + \mathfrak{a} = c + \mathfrak{a}$, whence we get the injectivity.
And if any $\mathfrak{a}_i$ is primary, then $\operatorname{zd}(R/\mathfrak{a}_i) = \operatorname{nil}(R/\mathfrak{a}_i)$ so $R/\mathfrak{a}$ is contained in a somewhat special ring. In this sense we will generalize this to the primary decomposition of modules, in section 5.1.

(2.98) Proposition: (viz. 1063)
Let $(R, +, \cdot)$ be a commutative ring and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be an ideal of R. If $\mathfrak{a}$ admits any primary decomposition, then it already admits a minimal primary decomposition. To be precise: Let $(\mathfrak{a}_1, \ldots, \mathfrak{a}_n)$ be any primary decomposition of $\mathfrak{a}$ then we obtain a minimal primary decomposition of $\mathfrak{a}$ by

(1) For any (non-empty) subset $N \subseteq 1\ldots n$ let us denote the intersection of all the $\mathfrak{a}_i$ for $i \in N$ by

$$\mathfrak{a}_N := \bigcap_{i \in N} \mathfrak{a}_i$$

Then we choose some $M \subseteq 1\ldots n$ with a minimal number of elements, such that $\mathfrak{a}_M = \mathfrak{a}$. That is $\mathfrak{a}_M = \mathfrak{a}$ but for any $L \subset M$ we have $\mathfrak{a}_L \neq \mathfrak{a}$.

(2) Now intersect all $\mathfrak{a}_i$ (where $i \in M$) that belong to the same prime ideal. That is we define an equivalence relation on M letting $i \approx j \ :\Longleftrightarrow\ \sqrt{\mathfrak{a}_i} = \sqrt{\mathfrak{a}_j}$. If we take to the quotient set $A := M/\approx$, then we have found a minimal primary decomposition $(\mathfrak{a}_\alpha)$ of $\mathfrak{a}$ (where $\alpha \in A$).

(2.99) Proposition: (viz. 1063)
Let $(R,+,\cdot)$ be a commutative ring, $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be a proper $\mathfrak{a} \neq R$ ideal and consider $(\mathfrak{a}_1,\ldots,\mathfrak{a}_k)$ a minimal primary decomposition of $\mathfrak{a}$. Let us further denote $\mathfrak{p}_i := \sqrt{\mathfrak{a}_i}$, then we obtain the following statements

(i) Clearly all the primary ideals and all the associated primary ideals of the decomposition are pairwise distinct, that is we have

$$\#\{\,\mathfrak{a}_1,\ldots,\mathfrak{a}_k\,\} \;=\; \#\{\,\mathfrak{p}_1,\ldots,\mathfrak{p}_k\,\} \;=\; k$$

(ii) For any $u \in R$ we obtain the following identity (where by convention the intersection over the empty set is defined to be the ring R itself)

$$\sqrt{\mathfrak{a} : u} \;=\; \bigcap \{\,\mathfrak{p}_i \mid i \in 1\ldots k,\; u \notin \mathfrak{a}_i\,\}$$

(iii) The prime ideals associated to $\mathfrak{a}$ are independent of the specific primary decomposition $(\mathfrak{a}_1,\ldots,\mathfrak{a}_k)$ chosen, as they can be described, as

$$\mathrm{ass}(\mathfrak{a}_1,\ldots,\mathfrak{a}_k) \;=\; \mathrm{Spec}(R) \cap \left\{\, \sqrt{\mathfrak{a} : u} \;\middle|\; u \in R \,\right\}$$

(iv) $(\diamondsuit)$ If $\mathfrak{p}_i$ is minimal among $\mathrm{ass}(\mathfrak{a}_1,\ldots,\mathfrak{a}_k)$ then we can reconstruct $\mathfrak{a}_i$ from $\mathfrak{a}$ and $\mathfrak{p}_i$. To be precise for any $i \in 1\ldots k$ we get

$$\mathfrak{p}_i \in \mathrm{ass}(\mathfrak{a}_1,\ldots,\mathfrak{a}_k)_* \quad\Longrightarrow\quad \mathfrak{a} : (R \setminus \mathfrak{p}_i) = \mathfrak{a}_i$$

(v) $(\diamondsuit)$ The isolated components of $\mathfrak{a}$ are independent of the specific primary decomposition $(\mathfrak{a}_1,\ldots,\mathfrak{a}_k)$ chosen, as they can be described, as

$$\mathrm{iso}(\mathfrak{a}_1,\ldots,\mathfrak{a}_k) \;=\; \{\,\mathfrak{a} : (R \setminus \mathfrak{p}) \;\mid\; \mathfrak{p} \in \mathrm{ass}(\mathfrak{a}_1,\ldots,\mathfrak{a}_k)_*\,\}$$

(2.100) Remark: $(\diamondsuit)$
In the items (iii) and (v) of the proposition we have seen, that the sets of associated prime ideals resp. of isolated components of an ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ are given to be the following:

$$\begin{aligned}
\mathrm{ass}(\mathfrak{a}) &:= \mathrm{Spec}(R) \cap \left\{\, \sqrt{\mathfrak{a} : u} \;\middle|\; u \in R \,\right\} \\
\mathrm{iso}(\mathfrak{a}) &:= \{\,\mathfrak{a} : (R \setminus \mathfrak{p}) \;\mid\; \mathfrak{p} \in \mathrm{ass}(\mathfrak{a})_*\,\}
\end{aligned}$$

That is if $(\mathfrak{a}_1,\ldots,\mathfrak{a}_k)$ is *any* minimal primary decomposition of $\mathfrak{a}$, then $\mathrm{ass}(\mathfrak{a}_1,\ldots,\mathfrak{a}_k) = \mathrm{ass}(\mathfrak{a})$ and $\mathrm{iso}(\mathfrak{a}_1,\ldots,\mathfrak{a}_k) = \mathrm{iso}(\mathfrak{a})$. In section 5.1 we will introduce the notion of a prime ideal *associated* to an R-module M. Thus if $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is an ideal, then it makes sense to the regard the prime ideals associated to $\mathfrak{a}$ as an R-module. And by definition this is just

$$\begin{aligned}
\mathrm{Sann}(\mathfrak{a}) &= \mathrm{Spec}(R) \cap \{\,\mathrm{ann}(a) \mid a \in \mathfrak{a}\,\} \\
&= \mathrm{Spec}(R) \cap \{\,0 : a \mid a \in \mathfrak{a}\,\}
\end{aligned}$$

(where the equality is due to $\mathrm{ann}(a) = 0 : a$ for any $a \in R$). Thus we find that at a first glance $\mathrm{Sann}(\mathfrak{a})$ has *absolutely nothing* to do with $\mathrm{ass}(\mathfrak{a})$. However it will turn out that the set $\mathrm{ass}(\mathfrak{a})$ is closely related to the set of associated prime ideals of the R-module $R/\mathfrak{a}$. By definition that is

$$\begin{aligned}\mathrm{Sann}_R\left(R\Big/\mathfrak{a}\right) &:= \mathrm{Spec}(R) \cap \left\{ \mathrm{ann}_R(x) \;\middle|\; x \in R\Big/\mathfrak{a} \right\} \\ &= \mathrm{Spec}(R) \cap \{\, \mathrm{ann}_R(b+\mathfrak{a}) \mid b \in R \,\} \\ &= \mathrm{Spec}(R) \cap \{\, \mathfrak{a} : b \mid b \in R \,\}\end{aligned}$$

(the latter equality is due to $\mathrm{ann}_R(b+\mathfrak{a}) = \mathfrak{a} : b$ for any $b \in R$ again). Thus the difference between this set and $\mathrm{ass}(\mathfrak{a})$ lies in the fact that $\mathrm{ass}(\mathfrak{a})$ allows the taking of radicals. Hence it is easy to see that $\mathrm{Sann}_R(R/\mathfrak{a}) \subseteq \mathrm{ass}(\mathfrak{a})$. In section 5.1 we will prove that for noetherian rings R we even have

$$\mathrm{Sann}_R\left(R\Big/\mathfrak{a}\right) = \mathrm{ass}(\mathfrak{a})$$

(2.101) Corollary: (viz. 1065) **Lasker-Noether**
Let $(R,+,\cdot)$ be a noetherian ring, then any proper ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$, $\mathfrak{a} \neq R$ admits a minimal primary decomposition. And in this decomposition the associated prime ideals and the isolated components are uniquely determined by $\mathfrak{a}$. Formally that is

(1) There are ideals $\mathfrak{a}_i \trianglelefteq_{\mathrm{i}} R$ (where $i \in 1 \ldots k$ and $1 \leq k \in \mathbb{N}$) such that $(\mathfrak{a}_1, \ldots, \mathfrak{a}_k)$ is a minimal primary decomposition of $\mathfrak{a}$.

(2) If $(\mathfrak{a}_1, \ldots, \mathfrak{a}_k)$ and $(\mathfrak{b}_1, \ldots, \mathfrak{b}_l)$ are any two minimal primary decompositions of $\mathfrak{a}$ then we obtain the following three identities

$$\begin{aligned} k &= l \\ \mathrm{ass}(\mathfrak{a}_1, \ldots, \mathfrak{a}_k) &= \mathrm{ass}(\mathfrak{b}_1, \ldots, \mathfrak{b}_l) \\ \mathrm{iso}(\mathfrak{a}_1, \ldots, \mathfrak{a}_k) &= \mathrm{iso}(\mathfrak{b}_1, \ldots, \mathfrak{b}_l) \end{aligned}$$

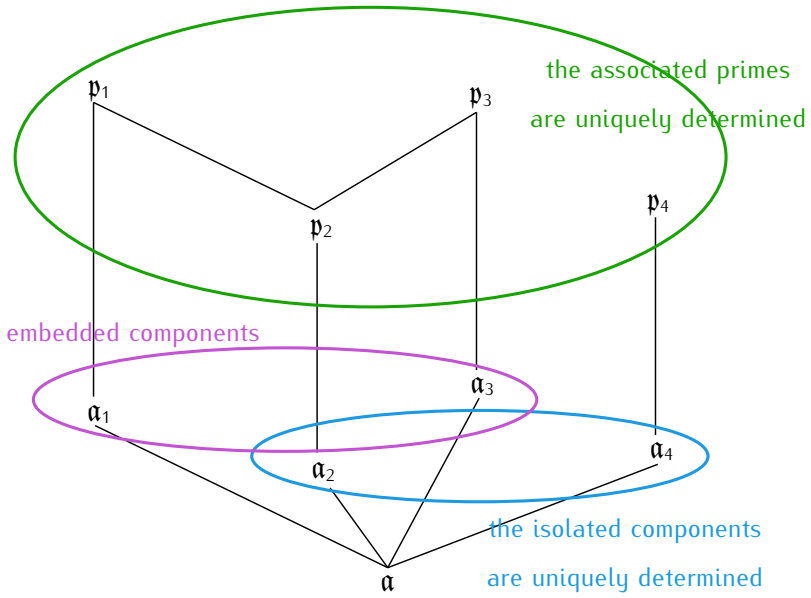
(3) If $\mathfrak{a} = \sqrt{\mathfrak{a}}$ is a radical ideal, then the minimal primary decomposition $(\mathfrak{a}_1, \ldots, \mathfrak{a}_k)$ of $\mathfrak{a}$ is uniquely determined (up to ordering) and consists precisely of the prime ideals minimal over $\mathfrak{a}$, formally

$$\{\, \mathfrak{a}_1, \ldots, \mathfrak{a}_k \,\} = \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p} \,\}_*$$

(2.102) Corollary: (viz. 1066)
Let $(R,+,\cdot)$ be a noetherian ring and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be a proper ideal of R (that is $\mathfrak{a} \neq R$). If now $\mathfrak{q} \trianglelefteq_{\mathrm{i}} R$ is any prime ideal of R then we obtain

(i) $\mathfrak{a}$ is contained in $\mathfrak{q}$ iff $\mathfrak{q}$ contains an associated prime ideal of $\mathfrak{a}$ iff $\mathfrak{q}$ contains an isolated component of $\mathfrak{a}$. Formally that is

$$\begin{aligned} \mathfrak{a} \subseteq \mathfrak{q} &\iff \exists\, \mathfrak{p} \in \mathrm{ass}(\mathfrak{a}) \,:\, \mathfrak{p} \subseteq \mathfrak{q} \\ &\iff \exists\, \mathfrak{i} \in \mathrm{iso}(\mathfrak{a}) \,:\, \mathfrak{i} \subseteq \mathfrak{q} \end{aligned}$$



(ii) The set of primes lying minimally over $\mathfrak{a}$ is precisely the set of primes belonging to the isolated components of $\mathfrak{a}$. Formally again

$$\{\, \mathfrak{q} \in \operatorname{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{q} \,\}_* \;=\; \operatorname{ass}(\mathfrak{a})_*$$

(iii) And thereby the radical of $\mathfrak{a}$ is precisely the intersection of all (minimal) associated prime ideals of $\mathfrak{a}$. Put formally that is

$$\sqrt{\mathfrak{a}} \;=\; \bigcap \operatorname{ass}(\mathfrak{a}) \;=\; \bigcap \operatorname{ass}(\mathfrak{a})_*$$

(2.103) Remark:
The following diagram should help to illustrate the situation a little: Suppose $(R, +, \cdot)$ is a noetherian ring and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is a proper $\mathfrak{a} \neq R$ ideal of R and pick up a minimal primary decomposition on $\mathfrak{a}$. As an example consider a decomposition of the following form: In this diagram

there are 4 associated primes $\mathfrak{p}_1$ to $\mathfrak{p}_4$. However both $\mathfrak{p}_1$ and $\mathfrak{p}_3$ contain $\mathfrak{p}_2$. Conversely $\mathfrak{p}_2$ and $\mathfrak{p}_4$ are the minimal associated primes of $\mathfrak{a}$. Hence $\mathfrak{q}_2$ and $\mathfrak{q}_4$ are the isolated components of $\mathfrak{a}$, whereas $\mathfrak{q}_1$ and $\mathfrak{q}_3$ are embedded components of $\mathfrak{a}$. From this we know that $\mathfrak{q}_2$ and $\mathfrak{q}_4$ are part of any minimal primary decomposition of $\mathfrak{a}$, whereas $\mathfrak{q}_1$ and $\mathfrak{q}_3$ may vary. Also the associated primes $\mathfrak{p}_1$ to $\mathfrak{p}_4$ always are uniquely determined. Thereby $\mathfrak{p}_2$ and $\mathfrak{p}_4$ are the prime ideals of R lying minimally over $\mathfrak{a}$ and hence

$$\sqrt{\mathfrak{a}} \;=\; \mathfrak{p}_2 \cap \mathfrak{p}_4$$

(2.104) Example:
Fix any field $(F,+,\cdot)$ and let $R := F[s,t]$ be the polynomial ring over E in s and t (note that R is noetherian due to Hilbert's basis theorem). Now consider the ideal $\mathfrak{a} := \langle s^2, st\rangle_{\mathfrak{i}}$. Then we obtain two distinct primary decompositions $(\mathfrak{a}_1,\mathfrak{a}_2)$ and $(\mathfrak{b}_1,\mathfrak{b}_2)$ of $\mathfrak{a}$ by letting

$$\begin{array}{lccc} & \mathfrak{a}_i & \mathfrak{b}_i & \mathfrak{p}_i \\ i=1 & \langle s\rangle_{\mathfrak{i}} & \langle s\rangle_{\mathfrak{i}} & \langle s\rangle_{\mathfrak{i}} \\ i=2 & \langle s^2,st,t^2\rangle_{\mathfrak{i}} & \langle s^2,t\rangle_{\mathfrak{i}} & \langle s,t\rangle_{\mathfrak{i}} \end{array}$$

where $\mathfrak{p}_i := \sqrt{\mathfrak{a}_i} = \sqrt{\mathfrak{b}_i}$. It is no coincidence that both primary decompositions have 2 elements and that the radicals $\mathfrak{p}_i$ are equal. Further $\mathfrak{p}_1 \subset \mathfrak{p}_2$, that is $\mathfrak{a}_1 = \mathfrak{b}_1$ are isolated components of $\mathfrak{a}$ and $\mathfrak{a}_2 \neq \mathfrak{b}_2$ are embedded components (of the decompositions). In fact this example demonstrates that the embedded components may be different.

$$\begin{aligned} \operatorname{ass}(\mathfrak{a}) &= \{\, sR, sR+tR \,\} \\ \operatorname{iso}(\mathfrak{a}) &= \{\, sR \,\} \end{aligned}$$

2.9 Finite Rings

(2.105) Definition: (viz. 1066)
Let $(R,+,\cdot)$ be any ring, denote its zero element by 0_R and its unit element by 1_R. For any $1 \leq k \in \mathbb{N}$ let us denote $k_R := k1_R = 1_R + \cdots + 1_R$ (k-times). Then there exists a uniquely determined homomrphism of rings ζ from $\mathbb{Z}$ to R, and this is given to be

$$\zeta \ : \ \mathbb{Z} \to R \ : \ k \mapsto \begin{cases} k_R \text{ if } k > 0 \\ 0_R \text{ if } k = 0 \\ -(-k)_R \text{ if } k < 0 \end{cases}$$

The image of ζ in R is said to be the **prime ring** of R and denoted by $\text{PRR}(R)$. In fact it is the smallest sub-ring of R in the following sense: it is the intersection of *all* sub-rings of R. Formally

$$\text{PRR}(R) \ := \ \text{im}(\zeta) \ = \ \bigcap \{ P \mid P \ \leq_{\text{r}} \ R \}$$

And the kernel of ζ is an ideal in $\mathbb{Z}$. Hence (as $\mathbb{Z}$ is a PID) there is a uniquely determined $n \in \mathbb{N}$ such that $\text{kn}(\zeta) = n\mathbb{Z}$. This number n is said to be the **characteristic** of R, denoted by

$$\text{CHAR}(R) \ := \ n \quad \text{where} \quad \text{kn}(\zeta) \ = \ n\mathbb{Z}$$

That is if R has characteristic zero $n = 0$, then we get $k_R = 0 \implies k = 0$. And if R has non-zero characteristic $n \neq 0$, then n is precisely the smallest number such that $n_R = 0$. Formally that is

$$\text{CHAR}(R) \ = \ \min\{ 1 \leq k \in \mathbb{N} \mid k_R = 0 \}$$

Also by construction of ζ and the first isomorphism theorem, if $n = \text{CHAR}(R)$ is the characteristic of R and we denote $\mathbb{Z}_0 := \mathbb{Z}$ and $\mathbb{Z}_n := \mathbb{Z}/n\mathbb{Z}$ for $n \geq 1$, then $\mathbb{Z}_n$ is embedded into R under

$$\mathbb{Z}_n \ \hookrightarrow \ R \ : \ k + n\mathbb{Z} \ \mapsto \ k_R$$

(2.106) Remark:
If $(F,+,\cdot)$ even is a field, we may also introduce the **prime field** of F (denoted by $\text{PRF}(F)$) to be the intersection of all subfields of F. Formally

$$\text{PRF}(F) \ := \ \bigcap \{ E \mid E \ \leq_{\text{f}} \ F \}$$

And if is easy to see that $\text{PRF}(F)$ is precisely the quotient field of the prime ring $\text{PRR}(F)$. Formally that is the following identity

$$\text{PRF}(F) \ = \ \left\{ ab^{-1} \mid a,b \in \text{PRR}(F),\ b \neq 0 \right\}$$

Prob as $E \ \leq_{\text{f}} \ F$ implies $E \ \leq_{\text{r}} \ F$ (by definition) we have $\text{PRR}(F) \subseteq \text{PRF}(F)$. Let us now denote the quotient field of $\text{PRR}(F)$ by $Q \subseteq F$. As $\text{PRF}(F)$ is a field and $\text{PRR}(F) \subseteq \text{PRF}(F)$ it is clear that $Q \subseteq \text{PRF}(F)$. On the other hand $Q \leq_{\text{f}} F$ is a subfield and hence we have $\text{PRF}(F) \subseteq Q$ by construction. Together this means $\text{PRF}(F) = Q$ as claimed.

(2.107) Proposition: (viz. 1067)
Let $(R,+,\cdot)$ be any ring, then the characteristic of R satisfies the following properties

(i) If $R \neq 0$ is a non-zero integral domain, then the characteristic of R is a prime number or zero. Formally that is the following implication

$$R \text{ integral domain, } R \neq 0 \quad \Longrightarrow \quad \text{CHAR}(R) = 0 \text{ or prime}$$

(ii) R has characteristic zero if and only if the prime ring of R is isomorphic to $\mathbb{Z}$. More precisely we find the following equivalences

$$\begin{aligned} \text{CHAR}(R) = 0 \quad &\Longleftrightarrow \quad \forall\, k \in \mathbb{N} \,:\, k_R = 0 \implies k = 0 \\ &\Longleftrightarrow \quad \mathbb{Z} \;\cong_{\mathrm{r}}\; \text{PRR}(R) : k \mapsto \zeta(k) \end{aligned}$$

(iii) R has non-zero characteristic $n = \text{CHAR}(R) > 0$ if and only if the prime ring of R is isomorphic to $\mathbb{Z}_n$. More precisely for any $1 \leq n \in \mathbb{N}$ we find the equivalence of the following statements

$$\begin{aligned} \text{CHAR}(R) = n \quad &\Longleftrightarrow \quad n = \min\{\, 1 \leq k \in \mathbb{N} \mid k_R = 0 \,\} \\ &\Longleftrightarrow \quad \mathbb{Z}_n \;\cong_{\mathrm{r}}\; \text{PRR}(R) : k + n\mathbb{Z} \mapsto \zeta(k) \end{aligned}$$

(iv) Now suppose that R is a field, then the prime field of R is given to be

$$\begin{aligned} \text{CHAR}(R) = 0 \quad &\Longleftrightarrow \quad \mathbb{Q} \;\cong_{\mathrm{r}}\; \text{PRF}(R) \\ \text{CHAR}(R) = p \neq 0 \quad &\Longleftrightarrow \quad \mathbb{Z}_p \;\cong_{\mathrm{r}}\; \text{PRF}(R) \end{aligned}$$

(v) Let $(R,+,\cdot)$ be a finite ring (that is $\#R < \infty$), then the characteristic of R is non-zero and divides the number of elements of R, formally once more

$$0 \neq \;\; \text{CHAR}(R) \mid \#R$$

(2.108) Example: (viz. 1068)
Fix $n \in \mathbb{N}$ and recall $\mathbb{Z}_n = \mathbb{Z}/n\mathbb{Z}$. In case $n = 0$ we have $n\mathbb{Z} = 0$ and hence $\mathbb{Z}_n = \mathbb{Z}$, which is an integral domain. In case $n = 1$ we have $n\mathbb{Z} = \mathbb{Z}$ and hence $\mathbb{Z}_n = 0$ is the zero-ring. And in case $n \geq 2$ we get the following equivalencies

(a) n is a prime number

(b) $\mathbb{Z}_n$ is a (finite) field

(c) $\mathbb{Z}_n$ is an integral domain

We even get a concrete description of the unit group of $\mathbb{Z}_n$: For any $n \geq 2$ the set of units of $\mathbb{Z}_n$ is given to be the set of all $k + n\mathbb{Z}$ such that k is relatively prime to n. Formally that is

$$\mathbb{Z}_n^* \;\; = \;\; \{\, k + n\mathbb{Z} \mid 1 \in \gcd(k,n) \,\}$$

Nota It is worthwhile to note that this matches (2.107.(i)) and (2.109.(i)). We also find a generalisation of this in (2.112) to the case of non-commutative rings. So while we could use all these propositions and theorems to patch together an abstract proof, we decided to give direct, autonomous argument.

(2.109) Proposition: (viz. 1069)

(i) Let $(R,+,\cdot)$ be a finite (that is $\#R < \infty$), commutative ring. Then the non-zero divisors of R already are invertible, such that we get the equality

$$R^* \;=\; R \setminus \mathrm{zd}(R)$$

(ii) Let $(F,+,\cdot)$ be any field and $G \leq_{\mathrm{g}} F^*$ be a subgroup of the multiplicative group of F. If G is finite then it already is cyclic (that is there is some $g \in G$ such that $G = \{1, g, g^2, \ldots, g^{n-1}\}$, where $n = \#G$ is the order of G). In particular the multiplicative group $(F^*,\cdot)$ of any finite field F is cyclic.

$$\#G < \infty \text{ finite} \quad \Longrightarrow \quad G \text{ cyclic}$$

(iii) Let $(F,+,\cdot)$ be a finite field $n := \#F$ the number of elements of F. Then for any $a \in F$ we have $a^n = a$ and we even find the following identity of polynomials in $F[t]$

$$\prod_{a \in F} (t - a) \;=\; t^n - t$$

(iv) Let $(S,+,\cdot)$ be an integral domain and consider a prime element $p \in S$. Let further $1 \leq n \in \mathbb{N}$ and denote the quotient ring $R := S/p^nS$. Then the set of zero-divisors of R is precisely the ideal generated by the residue class of p. Formally that is

$$\mathrm{zd}(R) \;=\; (p + p^nS)\,R$$

(v) Now let $(S,+,\cdot)$ be a PID, consider a prime element $p \in S$ and let $R := S/p^nS$ again. Then we obtain the following statements

$$\mathrm{nil}(R) \;=\; \mathrm{zd}(R) \;=\; R \setminus R^* \;=\; (p + p^nS)\,R$$

$$\mathrm{Spec}(R) \;=\; \mathrm{Smax}(R) \;=\; \{\, \mathrm{nil}(R) \,\}$$

(vi) Let $(R,+,\cdot)$ be any noetherian (in particular commutative) ring and fix any $1 \leq m \in \mathbb{N}$. Then there only are finitely many prime ideals $\mathfrak{p}$ of R such that $R/\mathfrak{p}$ has at most m elements. Formally

$$\#\left\{ \mathfrak{p} \in \mathrm{Spec}(R) \;\middle|\; \#{}^{R}\!\big/_{\mathfrak{p}} \leq m \right\} \;<\; \infty$$

(2.110) Remark: $(\diamondsuit)$
As in (iv) let $(S,+,\cdot)$ be a PID, $p \in S$ be a prime element and define $R := S/p^nS$ again. Then we have seen, that $\text{NIL}(R) = R \setminus R^*$ and we will later call a ring with such a property a local ring. To be precise: R is a *local ring* with maximal ideal $\text{NIL}(R)$. Further - in a fancier language - the property $\text{Spec}(R) = \text{Smax}(R)$ can be reformulated as "R is a *zero-dimensional* ring".

(2.111) Example:
The field of complex numbers $\mathbb{C}$ has an infinite subgroup of its multiplicative group $\mathbb{C}^*$, namely the one-dimensional torus $\mathbb{T} = \{ z \in \mathbb{C} \mid |z| = 1 \} = \{ a + ib \in \mathbb{C} \mid a^2 + b^2 = 1 \}$. We also get finite subgroups of $\mathbb{C}$ by fixing $1 \leq n \in \mathbb{N}$ and taking to

$$g_n \;:=\; \exp\left(\frac{2\pi}{n} i\right)$$

Then $\mathbb{T}_n := \{ g_n^k \mid k \in \mathbb{Z} \} = \{ 1, g, g^2, \ldots, g^{n-1} \}$ is a subgroup of $\mathbb{T}$, which is a subgroup of $\mathbb{C}^*$ in turn. In fact these are the only finite subgroups of $\mathbb{C}^*$, as the subgroups generator has to have absoulte value 1 (as it's n-th power is 1 and the absolute value is multiplicative).

(2.112) Theorem: (viz. 1072) **of Wedderburn**
Let $(F,+,\cdot)$ be an arbitrary ring with finitely many elements only (formally $\#F < \infty$), then the following three statements are equivalent

(a) F is a field

(b) F is a skew-field

(c) F is an integral domain

Fragments - algebra - rings: Frobenius automorphsim - proposition 11 to corollary 16

2.10 Localization of Rings

Localization is one of the most powerful and fundamental tools in commutative algebra - and luckily one of the most simple ones. The general idea of localization is to start with a commutative ring $(R,+,\cdot)$, to designate a sufficient subset $U \subseteq R$ and to enlarge R to the ring $U^{-1}R$ in which the elements of $u \in U \subseteq R \subseteq U^{-1}R$ now are units. And it will turn out, that in doing this the ideal structure of $U^{-1}R$ will be *easier* than that of R. And conversely we can restore information of R by regarding sufficiently many localizations of R (this will be the *local-global-principle*). These two properties give the method of localizing its punch. In fact commutative algebra has been most successful with problems that allowed localization. So let us finally begin with the fundamental definitions:

(2.113) Definition:
Let $(R,+,\cdot)$ be any commutative ring, then a subset $U \subseteq R$ is said to be **multiplicatively closed** iff it satisfies the following two properties

$$\begin{aligned} 1 &\in U \\ u,v \in U &\implies uv \in U \end{aligned}$$

And $U \subseteq R$ is said to be a **saturated** mutilplicative system, iff conversely the factors u and v of a product uv belonging to U already had to be elements of U. That is iff U satisfies

$$\begin{aligned} 1 &\in U \\ u,v \in U &\implies uv \in U \\ uv \in U &\implies u \in U \end{aligned}$$

(2.114) Proposition: (viz. 1074)

(i) In a commutative ring $(R,+,\cdot)$ the set R^* of units and the set $\mathrm{NZD}(R)$ of non-zero-divisors of R both are saturated multiplicatively closed subsets of R.

(ii) If $U \subseteq R$ is a saturated, multiplicatively closed set, then $R^* \subseteq U$, as for any $u \in R^*$ we get $uu^{-1} = 1 \in U$ and hence $u \in U$.

(iii) If U, $V \subseteq R$ are any multiplicatively closed sets in the commutative ring R, then their product $UV := \{\, uv \mid u \in U, v \in V \,\}$ is multiplicatively closed, too.

(iv) If $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is an ideal, then $1 + \mathfrak{a} \subseteq R$ is a multiplicatively closed subset.

(v) Let $\varphi : R \to S$ be a ring-homomorphism between the commutative rings R and S and consider $U \subseteq R$ and $V \subseteq V$. Then we get

$$\begin{array}{lcll} U & \text{mult. closed} & \implies & \varphi(U) \quad \text{mult. closed} \\ V & \text{mult. closed} & \implies & \varphi^{-1}(V) \quad \text{mult. closed} \\ V & \text{saturated} & \implies & \varphi^{-1}(V) \quad \text{saturated} \end{array}$$

(vi) If $\mathcal{U} \subseteq \mathcal{P}(R)$ is a chain (under $\subseteq$) of multiplicatively closed subsets of R, then the union $\bigcup \mathcal{U} \subseteq R$ is a multiplicatively closed set again.

(vii) If $\mathcal{U} \subseteq \mathcal{P}(R)$ is a non-empty ($\mathcal{U} \neq \emptyset$) family of [saturated] multiplicatively closed subsets of R, then the intersection $\bigcap \mathcal{U} \subseteq R$ is a [saturated] multiplicatively closed set, too.

NOTA this allows to define the *multiplicative closure* of a subset A of R to be the smallest multiplicatively closed set containing A, which is $\bigcap \{ U \subseteq R \mid A \subseteq U, U \text{ multiplicatively closed} \}$. Likewise we may define the *saturated multiplicative closure* of A to be the intersection of all saturated multiplicatively closed subsets containing A.

(viii) As an example consider any $u \in R$, then the set $U := \{ u^k \mid k \in \mathbb{N} \}$ clearly is a multiplicatively closed set. In fact it is the smallest multiplicatively closed set containing u. That is U is the multiplicative closure of $\{ u \}$.

(ix) Let $U \subseteq R$ be a multiplicatively closed subset of R, then the saturated multiplicative closure $\overline{U}$ of U can be given explicitly to be the set

$$\overline{U} \;=\; \{ a \in R \mid \exists\, b \in R, \exists\, u, v \in U : uab = uv \}$$

(2.115) Proposition: (viz. 1075)
Let $(R, +, \cdot)$ be any commutative ring and $U \subseteq R$ be a subset. Then U is saturated multiplicatively closed, iff it is the complement of a union of prime ideals of R. Formally that is the equivalence of

(a) $\exists\, \mathcal{P} \subseteq \operatorname{Spec}(R)$ such that $U = R \setminus \bigcup \mathcal{P}$

(b) $U \subseteq R$ is a saturated multiplicatively closed subset

(2.116) Definition: (viz. 1075)
Let $(R, +, \cdot)$ be any commutative ring and $U \subseteq R$ be a multiplicatively closed subset of R. Then we obtain an equivalence relation $\sim$ on the set $U \times R$ by virtue of (with $a, b \in R$ and $u, v \in U$)

$$(u, a) \sim (v, b) \quad :\Longleftrightarrow \quad \exists\, w \in U \;:\; vwa = uwb$$

And we denote the quotient of $U \times R$ modulo $\sim$ by $U^{-1}R$ and the equivalence class of (u, a) is denoted by a/u, formally this is the following construction

$$\begin{aligned} \frac{a}{u} &:= \{ (v, b) \in U \times R \mid (u, a) \sim (v, b) \} \\ U^{-1}R &:= U \times R \Big/ \sim \end{aligned}$$

Now $U^{-1}R$ becomes a commutative ring under the following addition and multiplication of its elements

$$\begin{aligned} \frac{a}{u} + \frac{b}{v} &:= \frac{av + bu}{uv} \\ \frac{a}{u} \cdot \frac{b}{v} &:= \frac{ab}{uv} \end{aligned}$$

It is clear that under these operations the zero-element of $U^{-1}R$ is given to be $0/1$ and the unit element of $U^{-1}R$ is given to be $1/1$. And we obtain a canonical ring homomorphism from R to $U^{-1}R$ by letting

$$\kappa \;:\; R \to U^{-1}R \;:\; a \mapsto \frac{a}{1}$$

In general this canonical homomorphism need not be and embedding (i.e. injective). Yet we do obtain the following equivalences regarding this homomorphism

$$\begin{aligned} \kappa \text{ injective} &\iff U \subseteq \text{NZD}(R) \\ \kappa \text{ bijective} &\iff U \subseteq R^* \end{aligned}$$

(2.117) Remark:

- Though the equivalence relation $\sim$ in the above definition might look a little artificial at first sight nothing here is mythical or mere chance. To see this let us first consider the case of an integral domain $(R, +, \cdot)$. Then we may divide by w and hence we get

 $$\frac{a}{u} = \frac{b}{v} \iff va = ub$$

 and this is just what we expect, if we multiply the left-hand equation by uv. To allow a common factor w is just the right way to deal with zero divisors in R. For convenience we repeat the defining property of the quotient a/u for general commutative rings $(R, +, \cdot)$

 $$\frac{a}{u} = \frac{b}{v} \iff \exists\, w \in U \;:\; vwa = uwb$$

- And from this equivalence it is immediately clear that fractions a/u in $U^{-1}R$ can be reduced by common factors v of U. That is for any elements $a \in R$ and $u, v \in U$ we have the equality

 $$\frac{av}{uv} = \frac{a}{u}$$

 And this allows to express sums by going to a common denominator. That is consider $a_1, \ldots, a_n \in R$ and $u_1, \ldots, u_n \in U$. Then we denote $u := u_1 \ldots u_n \in U$ and $\widehat{u}_i := u/u_i \in U$ (e.g. $\widehat{u}_1 = u_2 \ldots u_n$). Then we have just remarked that $a_i/u_i = (a_i\widehat{u}_i)/u$ and thereby

 $$\frac{a_1}{u_1} + \cdots + \frac{a_n}{u_n} = \frac{a_1\widehat{u}_1 + \cdots + a_n\widehat{u}_n}{u}$$

- This equivalence also yields that $1/1 = 0/1$ holds true in $U^{-1}R$ if and only if the multiplicatively closed set contains zero $0 \in U$. But as $0/1$ is the zero-element and $1/1$ is the unit element of $U^{-1}R$ we thereby found another equivalence

 $$U^{-1}R = 0 \iff 0 \in U$$

- As we have intended, localizing turns the elements $u \in U$ into units of $U^{-1}R$. More precisely if $U \subseteq R$ is multiplicatively closed, then we obtain

$$\left(U^{-1}R\right)^* \quad \supseteq \quad \left\{ \frac{au}{v} \;\middle|\; a \in R^*, u, v \in U \right\}$$

 Prob consider any au/v such that $a \in R^*$ and u, $v \in U$, then we compute $(au/v)(a^{-1}v/u) = (aa^{-1}uv)/(uv) = (uv)/(uv) = 1/1$ and hence au/v is a unit, with inverse $(au/v)^{-1} = a^{-1}v/u$.

 Nota However the equality need not hold true! As an example consider the integers $R = \mathbb{Z}$ and let $U = \left\{ 6^k \mid k \in \mathbb{N} \right\} = \{1, 6, 36, \dots\}$. Then $2/1$ is invertible, with inverse $(2/1)^{-1} = 3/6$, yet $2/1$ is not of the form $R^*U/U = \left\{ \pm 6^k \mid k \in \mathbb{Z} \right\} \subseteq \mathbb{Q}$.

- If $U \subseteq R$ even is a saturated multiplicatively closed subset, then we obtain a complete description of the units of $U^{-1}R$ to be the fractions u/v of elements u, $v \in U$. Formally that is

$$\left(U^{-1}R\right)^* \quad = \quad \left\{ \frac{u}{v} \;\middle|\; u, v \in U \right\}$$

 Prob clearly u/v is a unit of $U^{-1}R$, since $(u/v)^{-1} = v/u$. Conversely if b/v is a unit of $U^{-1}R$ there is some $a/u \in U^{-1}R$ such that $ab/uv = (a/u)(b/v) = 1/1$. That is there is some $w \in U$ such that $abw = uvw$. Hence $b(aw) = uvw \in U$ and as U is saturated this implies $b \in U$.

- Let $(R, +, \cdot)$ be a commutative ring and $U \subseteq R$ be a multiplicatively closed set, such that $U^{-1}R$ is finitely generated as an R-module. That is there are $b_1, \dots, b_n \in R$ and $v_1, \dots . v_n \in U$ such that

$$U^{-1}R \quad = \quad \left\{ \frac{a_1 b_1}{v_1} + \cdots + \frac{a_n b_n}{v_n} \;\middle|\; a_1, \dots, a_n \in R \right\}$$

 Then the canonical mapping $\kappa : R \to U^{-1}R : b \mapsto b/1$ is surjective. Prob consider any $a/u \in U^{-1}R$ and denote $v := v_1 \dots v_n \in U$ and $\widehat{v}_i := v/v_i \in V$ (e.g. $\widehat{v}_1 = v_2 \dots v_n$). As $uv \in V$ and $U^{-1}R$ is generated by the b_i/v_1 there are $a_1, \dots, a_n \in R$ such that

$$\frac{a}{uv} \quad = \quad \frac{a_1 b_1}{v_1} + \cdots + \frac{a_n b_n}{v_n} \quad = \quad \frac{a_1 b_1 \widehat{v}_1 + \cdots + a_n b_n \widehat{v}_n}{v}$$

 That is there is some $w \in U$ such that $vwa = uvwb$ where we let $b := a_1 b_1 \widehat{v}_1 + \cdots + a_n b_n \widehat{v}_n \in R$. That is we have found $(vw)1a = (vw)ub$, thus by definition we have $\kappa(b) = b/1 = a/u$. And as a/u has been arbitrary this is the surjectivity of κ.

- If $U \subseteq R$ is multiplicatively closed and we consider $R \subseteq R[t]$ as a subset of the polynomial ring $R[t]$, then we will see in (2.132.(i)) that the localisation of the polynomial ring is just the same as the polynomial ring of the localisation. That is we have the following isomorphism of rings

$$\begin{array}{rcl} U^{-1}\big(R[t]\big) & \cong_{\mathrm{r}} & \big(U^{-1}R\big)[t] \\ \dfrac{f}{u} & \mapsto & \displaystyle\sum_{k=0}^{\infty} \frac{f[k]}{u} t^k \end{array}$$

(2.118) Example:
Let now $(R,+,\cdot)$ be any commutative ring. Then we present three examples that are of utmost importance. Hence the reader is asked to regard these examples as definitions of the objects R_u, $\mathrm{QUOT}(R)$ and $R_\mathfrak{p}$.

- If R is an integral domain and $0 \notin U$, then $a/u = b/v$ is equivalent, to $va = ub$, as we can eliminate $w \neq 0$ from $w(va - ub) = 0$. In particular for $U = R \setminus \{0\}$ the construction of $U^{-1}R$ can be simplified somewhat: First let $Q := \{\, (a,u) \in R^2 \mid u \neq 0 \,\}$, then we obtain an equivalence relation on Q by letting $(a,u) \sim (b,v) \;:\Longleftrightarrow\; va = ub$. Let us denote the equivalence class of (a,u) by $a/u := [(a,u)]$ again. Then we have regained the **quotient field** of R as in section 1.4

$$\mathrm{QUOT}(R) \;=\; \left\{ \frac{a}{b} \;\middle|\; a,b \in R,\ b \neq 0 \right\}$$

 Note that this is precisely the construction that is used to obtain $\mathbb{Q}$ from $\mathbb{Z}$. If now $U \subseteq R$ is an arbitrary multiplicatively closed set satisfying $0 \notin U$, then the localization of R in U is canonically isomorphic to the following sub-ring of the quotient field:

$$U^{-1}R \;\cong_\mathrm{r}\; \left\{ \frac{a}{u} \in \mathrm{QUOT}(R) \;\middle|\; a \in R, u \in U \right\} \;:\; \frac{a}{u} \mapsto \frac{a}{u}$$

 Prob we will first prove the well-definedness and injectivity: By definition $a/u = b/v$ in $U^{-1}R$ is equivalent to $w(av - bu) = 0$ for some $w \in U$. But as $0 \notin U$ we get $w \neq 0$ and hence $av = bu$, as R is an integral domain. This again is just $a/u = b/v$ in $\mathrm{QUOT}(R)$. The surjectivity of the map is obvious and it clearly is a homomorphism, as the algebraic operations are literally the same.

- Let us generalize the previous construction a little: It is clear that the set $U := \mathrm{NZD}(R)$ of non-zero divisors of R is a saturated multiplicatively closed set. Thus we may define the **total ring of fractions** of a commutative ring R to be the localization in this set

$$\mathrm{QUOT}(R) \;:=\; (\mathrm{NZD}R)^{-1} R$$

 Note that in case of an integral domain we have $\mathrm{NZD}(R) = R \setminus \{0\}$ and hence we obtain precisely the same ring as before. Further note that by the very nature of $U = \mathrm{NZD}(R)$ the canonical homomorphism κ is injective. That is we can always regard R as a sub-ring of $\mathrm{QUOT}(R)$

$$R \hookrightarrow \mathrm{QUOT}(R) \;:\; a \mapsto a/1 \text{ is injective}$$

 And as $\mathrm{NZD}(R)$ is saturated we can give the units of $\mathrm{QUOT}(R)$ explicitly

$$(\mathrm{QUOT}(R))^* \;=\; \left\{ \frac{u}{v} \;\middle|\; u,v \in \mathrm{NZD}(R) \right\}$$

 In particular we find that $\mathrm{QUOT}(R)$ is a field if and only if $\mathrm{NZD}(R) = R \setminus \{0\}$ and this is precisely the property of R being an integral domain. That is we obtain the equivalence

$$R \text{ integral domain} \;\Longleftrightarrow\; \mathrm{QUOT}(R) \text{ field}$$

- Consider some field $(F,+,\cdot)$ and a sub-ring $R \leq_{\mathrm{r}} F$. In particular $R \neq 0$ is a non-zero integral domain and hence $\mathrm{QUOT}(R)$ is a field. Let us now denote the subfield of F generated by R by E, which is given to be

$$E \;:=\; \left\{ ab^{-1} \mid a,b \in R \right\}$$

Then is is straightforward to check that the algebraic operations on the quotient field $\mathrm{QUOT}(R)$ coincide with those of the field E. That is we obtain a well-defined isomorphism of rings

$$\mathrm{QUOT}(R) \;\cong_{\mathrm{r}}\; E \;:\; \frac{a}{b} \mapsto ab^{-1}$$

- Consider any $u \in R$, then clearly $U := \left\{ 1, u, u^2, u^3, \ldots \right\}$ is multiplicatively closed. Hence we obtain a commutative ring by localizing

$$R_u \;:=\; \left\{ u^k \;\middle|\; k \in \mathbb{N} \right\}^{-1} R$$

in which $u = u/1$ is invertible (with inverse $1/u$). By the remarks above it is clear that $R_u = 0$ is zero if and only if u is a nilpotent of R. And $R \hookrightarrow R_u$ is embedded under κ if and only if u is a non-zero divisor of R, respectively isomorphic if u is a unit. Altogether

$$\begin{aligned} R_u = 0 \quad &\Longleftrightarrow \quad u \in \mathrm{NIL}(R) \\ \kappa : R \hookrightarrow R_u \quad &\Longleftrightarrow \quad u \in \mathrm{NZD}(R) \\ \kappa : R \cong_{\mathrm{r}} R_u \quad &\Longleftrightarrow \quad u \in R^* \end{aligned}$$

- In (2.12) and (in a more general version) in (2.115) we have seen, that the complement $R \setminus \mathfrak{p}$ of a prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ is a saturated, multiplicatively closed set. Thus for prime ideals $\mathfrak{p}$ we may always define the localization

$$R_{\mathfrak{p}} \;:=\; (R \setminus \mathfrak{p})^{-1} R$$

And by going to complements it is clear that R is embedded into $R_{\mathfrak{p}}$ under κ, iff $\mathfrak{p}$ is contained in the set of zero divisors of R

$$\kappa : R \hookrightarrow R_{\mathfrak{p}} \quad \Longleftrightarrow \quad \mathfrak{p} \subseteq \mathrm{ZD}(R)$$

In any case - as $R \setminus \mathfrak{p}$ is saturated multiplicatively closed subset - we can explicitly describe the group of units of $R_{\mathfrak{p}}$ to be

$$(R_{\mathfrak{p}})^* \;=\; \left\{ \frac{u}{v} \;\middle|\; u,v \notin \mathfrak{p} \right\}$$

- If $(R,+,\cdot)$ is an integral domain and $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ is a prime ideal of R then we get an easy alternative description of the localized ring $R_{\mathfrak{p}}$: Let $E := \mathrm{QUOT}(R)$ be the quotient field of R, then we denote:

$$E_{\mathfrak{p}} \;:=\; \left\{ \frac{a}{b} \in E \;\middle|\; b \notin \mathfrak{p} \right\}$$

And thereby we obtain a canonical isomorphism from the localized ring $R_{\mathfrak{p}}$ to $E_{\mathfrak{p}}$ by $a/b \mapsto a/b$

$$R_{\mathfrak{p}} \;\cong_{\mathrm{r}}\; E_{\mathfrak{p}} \;:\; \frac{a}{b} \mapsto \frac{a}{b}$$

One might be tempted to say $R_\mathfrak{p} = E_\mathfrak{p}$, but - from a set-theoretical point of view - this is not quite true, as the equivalence class $a/b \in R_\mathfrak{p}$ only is a subset of $a/b \in E_\mathfrak{p}$. Note that under this isomorphism the maximal ideal $\mathfrak{m}_\mathfrak{p} := \mathfrak{p}R_\mathfrak{p} = (R \setminus \mathfrak{p})^{-1}\mathfrak{p}$ (that is induced by $\mathfrak{p}$) in $R_\mathfrak{p}$ corresponds to the following maximal ideal in $E_\mathfrak{p}$

$$\mathfrak{m}_\mathfrak{p} \quad \longleftrightarrow \quad \left\{ \frac{a}{b} \in E \;\middle|\; a \in \mathfrak{p},\ b \notin \mathfrak{p} \right\}$$

(2.119) Proposition: (viz. 1084)
Consider any two commutative rings $(R, +, \cdot)$ and $(S, +, \cdot)$, a multiplicatively closed set $U \subseteq R$ and a homomorphism $\varphi : R \to S$ of rings. Then $\varphi(U) \subseteq S$ is mutiplicatively closed again and we obtain a well-defined homomorphism of rings of the form

$$U^{-1}\varphi \;:\; U^{-1}R \to \varphi(U)^{-1}S \;:\; \frac{a}{u} \mapsto \frac{\varphi(a)}{\varphi(u)}$$

Thereby if φ is injective, surjective or bijective, then $U^{-1}\varphi$ satisfies the same property.

(2.120) Proposition: (viz. 1085)
Universal Property: Let $(R, +, \cdot)$ and $(S, +, \cdot)$ be commutative rings, $U \subseteq R$ be a multiplicatively closed subset and $\varphi : R \to S$ be a homomorphism of rings, such that $\varphi(U) \subseteq S^*$. Then there is a uniquely determined homomorphism of rings $\overline{\varphi} : U^{-1}R \to S$ such that $\overline{\varphi}\kappa = \varphi$. And this is given to be

$$\overline{\varphi} \;:\; U^{-1}R \to S \;:\; \frac{a}{u} \mapsto \varphi(a)\,\varphi(u)^{-1}$$

(2.121) Remark:
Let $(R, +, \cdot)$ be a commutative ring and $U, V \subseteq R$ be multiplicatively closed sets, such that $U \subseteq V$. Further consider the canonical homomorphism $\kappa : R \to V^{-1}R : a \mapsto a/1$. Then it is clear that $\kappa(U) \subseteq (V^{-1}R)^*$, as the inverse of $u/1$ is given to be $1/u$. Thus by the above proposition we obtain an induced homomorphism of the form

$$\overline{\kappa} \;:\; U^{-1}R \to V^{-1}R \;:\; \frac{a}{u} \mapsto \frac{a}{u}$$

Thereby $\overline{\kappa}(a/u) = 0/1$ iff there is some $v \in V$ such that $va = 0$. And this is precisely the same property for $\kappa(a) = 0/1$. Hence the kernel of $\overline{\kappa}$ is just

$$\mathrm{kn}(\overline{\kappa}) \;=\; U^{-1}(\mathrm{kn}(\kappa)) \;=\; \left\{ \frac{a}{u} \;\middle|\; a \in \mathrm{kn}(\kappa), u \in U \right\}$$

(2.122) Definition: (viz. 1086)
Let $(R, +, \cdot)$ be a commutative ring, $U \subseteq R$ be a multiplicatively closed set and denote the canonical homomorphism, by $\kappa : R \to U^{-1}R : a \mapsto a/1$ again. If now $\mathfrak{a} \trianglelefteq_\mathrm{i} R$ and $\mathfrak{u} \trianglelefteq_\mathrm{i} U^{-1}R$ are ideals then we define the transferred ideals $\mathfrak{u} \cap R \trianglelefteq_\mathrm{i} R$ and $U^{-1}\mathfrak{a} \trianglelefteq_\mathrm{i} U^{-1}R$ to be the following

$$\begin{aligned} \mathfrak{u} \cap R \;&:=\; \kappa^{-1}(\mathfrak{u}) \;=\; \left\{ a \in R \;\middle|\; \frac{a}{1} \in \mathfrak{u} \right\} \\ U^{-1}\mathfrak{a} \;&:=\; \langle \kappa(\mathfrak{a}) \rangle_\mathrm{i} \;=\; \left\{ \frac{a}{u} \;\middle|\; a \in \mathfrak{a}, u \in U \right\} \end{aligned}$$

(2.123) Example:
Let $(R,+,\cdot)$ be any commutative ring, $a \in R$ and $U \subseteq R$ be multiplicatively closed. Then an easy, straightforward computation shows the identity of the principal ideals

$$U^{-1}(aR) \;=\; \frac{a}{1}\,U^{-1}R$$

(2.124) Definition: (viz. 1086)
Let $(R,+,\cdot)$ be a commutative ring, $U \subseteq R$ be a multiplicatively closed set and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be an ideal of R. Then we obtain another ideal $\mathfrak{a} : U \trianglelefteq_{\mathrm{i}} R$ by letting

$$\mathfrak{a} : U \;:=\; \{\, b \in R \mid \exists\, v \in U : vb \in \mathfrak{a} \,\}$$

And clearly $\mathfrak{a} : U \trianglelefteq_{\mathrm{i}} R$ thereby is an ideal of R containing $\mathfrak{a} \subseteq \mathfrak{a} : U$ and using the notation of (2.122) we finally obtain the equality

$$\left(U^{-1}\mathfrak{a}\right) \cap R \;=\; \mathfrak{a} : U$$

(2.125) Proposition: (viz. 1087)
Let $(R,+,\cdot)$ be a commutative ring and $U \subseteq R$ be a multiplicatively closed subset. Further let $\mathfrak{a}, \mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ be any two ideals of R, then we obtain

$$\begin{aligned}
U^{-1}(\mathfrak{a} \cap \mathfrak{b}) &= \left(U^{-1}\mathfrak{a}\right) \cap \left(U^{-1}\mathfrak{b}\right) \\
U^{-1}(\mathfrak{a} + \mathfrak{b}) &= \left(U^{-1}\mathfrak{a}\right) + \left(U^{-1}\mathfrak{b}\right) \\
U^{-1}(\mathfrak{a}\,\mathfrak{b}) &= \left(U^{-1}\mathfrak{a}\right)\left(U^{-1}\mathfrak{b}\right) \\
U^{-1}\sqrt{\mathfrak{a}} &= \sqrt{U^{-1}\mathfrak{a}}
\end{aligned}$$

$$\begin{aligned}
(\mathfrak{a} : U) : U &= \mathfrak{a} : U \\
(\mathfrak{a} \cap \mathfrak{b}) : U &= (\mathfrak{a} : U) \cap (\mathfrak{b} : U) \\
\sqrt{\mathfrak{a}} : U &= \sqrt{\mathfrak{a} : U}
\end{aligned}$$

Conversely consider any two ideals $\mathfrak{u}, \mathfrak{w} \trianglelefteq_{\mathrm{i}} U^{-1}R$ and abbreviate $\mathfrak{a} := \mathfrak{u} \cap R$ and $\mathfrak{b} := \mathfrak{w} \cap R \trianglelefteq_{\mathrm{i}} R$. Then we likewise get the additional identities

$$\begin{aligned}
(\mathfrak{u} \cap \mathfrak{w}) \cap R &= \mathfrak{a} \cap \mathfrak{b} \\
(\mathfrak{u} + \mathfrak{w}) \cap R &= (\mathfrak{a} + \mathfrak{b}) : U \\
(\mathfrak{u}\,\mathfrak{w}) \cap R &= (\mathfrak{a}\,\mathfrak{b}) : U \\
\sqrt{\mathfrak{u}} \cap R &= \sqrt{\mathfrak{a}}
\end{aligned}$$

(2.126) Example:
The equality $(\mathfrak{a} + \mathfrak{b}) : U = (\mathfrak{a} : U) + (\mathfrak{b} : U)$ need *not* hold true. As a counter-example consider $R = \mathbb{Z}$, $U := \{1, 2, 4, 8, \ldots\}$, $\mathfrak{a} = 9\mathbb{Z}$ and $\mathfrak{b} = 15\mathbb{Z}$. Then it is clear that $\mathfrak{a} : U = \mathfrak{a}$ and $\mathfrak{b} : U = \mathfrak{b}$ such that $(\mathfrak{a} : U) + (\mathfrak{b} : U) = 3\mathbb{Z}$ (as 3 is the greatest common divisor of 9 and 15). Yet $13 \cdot 2 = 26 = 9 + 15 \in \mathfrak{a} + \mathfrak{b}$. Thus $13 \in (\mathfrak{a} + \mathfrak{b}) : U$ even though $13 \notin 3\mathbb{Z} = (\mathfrak{a} : U) + (\mathfrak{b} : U)$.

(2.127) Proposition: (viz. 1088)
Let $(R,+,\cdot)$ be a commutative ring, $U \subseteq R$ be a multiplicatively closed subset and $I \neq \emptyset$ a non-empty index set. Suppose for any $i \in I$ we have an ideal $\mathfrak{a}_i \trianglelefteq_{\mathrm{i}} R$, then we get the following inclusion

$$U^{-1}\left(\bigcap_{i\in I}\mathfrak{a}_i\right) \quad\subseteq\quad \bigcap_{i\in I}\left(U^{-1}\mathfrak{a}_i\right)$$

And if for any $i \in I$ we even have a prime ideal $\mathfrak{p}_i \trianglelefteq_{\mathrm{i}} R$ with $\mathfrak{p}_i \cap U = \emptyset$ and an arbitrary ideal $\mathfrak{u}_i \trianglelefteq_{\mathrm{i}} U^{-1}R$ then we find the following identities: Nota Part of this proposition will be generalized to the transfer of ideals in general ring extensions in (8.21).

$$\begin{aligned} U^{-1}\left(\bigcap_{i\in I}\mathfrak{p}_i\right) &= \bigcap_{i\in I}\left(U^{-1}\mathfrak{p}_i\right) \\ \left(\bigcap_{i\in I}\mathfrak{u}_i\right)\cap R &= \bigcap_{i\in I}\left(\mathfrak{u}_i\cap R\right) \end{aligned}$$

(2.128) Definition: (viz. 1089)
Let $(R,+,\cdot)$ be a commutative ring and $U \subseteq R$ be a multiplicatively closed set in R. Then we define the following sets of ideals in R

$$\begin{aligned} U^{-1}\big(\mathsf{Ideal}(R)\big) &:= \{\,\mathfrak{a}\in\mathsf{Ideal}(R)\mid \mathfrak{a}=\mathfrak{a}:U\,\} \\ &= \left\{\,\mathfrak{a}\in\mathsf{Ideal}(R)\;\middle|\;\begin{array}{l}\forall\, a\in R \text{ we get the implication}\\ \big(\exists\, u\in U : ua\in\mathfrak{a}\big)\implies a\in\mathfrak{a}\end{array}\right\} \\ U^{-1}\big(\mathsf{Srad}(R)\big) &:= \mathsf{Srad}(R)\cap U^{-1}\big(\mathsf{Ideal}(R)\big) \\ U^{-1}\big(\mathsf{Spec}(R)\big) &:= \mathsf{Spec}(R)\cap U^{-1}\big(\mathsf{Ideal}(R)\big) \\ &= \{\,\mathfrak{p}\in\mathsf{Spec}(R)\mid \mathfrak{p}\cap U=\emptyset\,\} \\ U^{-1}\big(\mathsf{Smax}(R)\big) &:= \{\,\mathfrak{a}\in\mathsf{Ideal}(R)\mid \mathfrak{a}\cap U=\emptyset\,\}^{*} \end{aligned}$$

Nota explicitly an ideal $\mathfrak{m}$ of R is contained in $U^{-1}\mathsf{Smax}(R)$ iff it satisfies (1) $\mathfrak{m} \subseteq R\setminus U$ and (2) for any other $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ we have the implication $\mathfrak{m}\subseteq\mathfrak{a}\subseteq R\setminus U \implies \mathfrak{m}=\mathfrak{a}$.

(2.129) Proposition: (viz. 1089)
Let $(R,+,\cdot)$ be a commutative ring and $U \subseteq R$ be a multiplicatively closed set in R. Then we obtain an order-preserving one-to-one correspondence between the ideals of the localization $U^{-1}R$ and $U^{-1}\mathsf{Ideal}(R)$, formally this is

$$\begin{aligned} \mathsf{Ideal}(U^{-1}R) &\longleftrightarrow U^{-1}\big(\mathsf{Ideal}(R)\big) \\ \mathfrak{u} &\mapsto \mathfrak{u}\cap R \\ U^{-1}\mathfrak{a} &\hookleftarrow \mathfrak{a} \end{aligned}$$

- This correspondence is order-preserving, that is for any two ideals $\mathfrak{a}, \mathfrak{b} \in U^{-1}\mathrm{Ideal}(R)$ respectively for $\mathfrak{u}, \mathfrak{w} \in \mathrm{Ideal}U^{-1}R$ we find the implications

$$\begin{aligned} \mathfrak{a} \subseteq \mathfrak{b} &\implies U^{-1}\mathfrak{a} \subseteq U^{-1}\mathfrak{b} \\ \mathfrak{u} \subseteq \mathfrak{w} &\implies \mathfrak{u} \cap R \subseteq \mathfrak{w} \cap R \end{aligned}$$

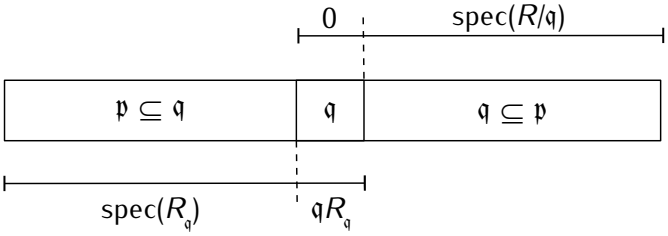
- And this correspondence correlates maximal, prime and radical ideals of $U^{-1}R$ with $U^{-1}\mathrm{Smax}(R)$, $U^{-1}\mathrm{Spec}(R)$ respectively with $U^{-1}\mathrm{Srad}(R)$

$$\begin{array}{rcl} \mathrm{Ideal}\big(U^{-1}R\big) & \longleftrightarrow & U^{-1}\big(\mathrm{Ideal}(R)\big) \\ \cup & & \cup \\ \mathrm{Srad}\big(U^{-1}R\big) & \longleftrightarrow & U^{-1}\big(\mathrm{Srad}(R)\big) \\ \cup & & \cup \\ \mathrm{Spec}\big(U^{-1}R\big) & \longleftrightarrow & U^{-1}\big(\mathrm{Spec}(R)\big) \\ \cup & & \cup \\ \mathrm{Smax}\big(U^{-1}R\big) & \longleftrightarrow & U^{-1}\big(\mathrm{Smax}(R)\big) \end{array}$$

(2.130) Example:

- Thus the ideal structure of $U^{-1}R$ is simpler than that of R itself. The most drastic example is the following: $\mathbb{Z}$ has a multitude of ideals (namely all $a\mathbb{Z}$ where $a \in \mathbb{N}$, which are countably many). Yet $\mathbb{Q} = \mathrm{QUOT}(\mathbb{Z})$ if a field and hence only has the trivial ideals 0 and $\mathbb{Q}$ itself.

- Let now $(R, +, \cdot)$ be any commutative ring and choose any $u \in R$, then the spectrum of R_u corresponds (under the mapping $\mathfrak{u} \mapsto \mathfrak{u} \cap R$ of the proposition above) to the following subset of the spectrum of R. In (2.172.(vi)) we will also prove the likewise inclusion of the maximal ideals



$$\begin{array}{rcl} \mathrm{Spec}\big(R_u\big) & \longleftrightarrow & \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid u \notin \mathfrak{p} \,\} \\ \cup & & \cup \\ \mathrm{Smax}\big(R_u\big) & \longleftrightarrow & \{\, \mathfrak{b} \in \mathrm{Ideal}(R) \mid u \notin \mathfrak{b} \,\}^* \end{array}$$

 Prob For a prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ the property $u \in \mathfrak{p}$ is equivalent, to $\{\, u, u^2, u^3, \dots \,\} \subseteq \mathfrak{p}$. But this again is equivalent, to $\mathfrak{p} \cap \{\, u, u^2, u^3, \dots \,\} \neq \emptyset$ such that the claim is immediate from (2.129).

- Let $\mathfrak{q} \in \mathrm{Spec}(R)$ be a fixed prime ideal of R, then (for any other prime ideal $\mathfrak{p}$ of R) clearly $\mathfrak{p} \cap (R \setminus \mathfrak{q}) = \emptyset$ is equivalent to $\mathfrak{p} \subseteq \mathfrak{q}$. Using this in the above proposition (2.129) we find the correspondence

$$\mathrm{Spec}(R_{\mathfrak{q}}) \longleftrightarrow \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{p} \subseteq \mathfrak{q} \,\}$$

 Thus localizing in $\mathfrak{q}$ simply preserves the prime ideals below $\mathfrak{q}$ and deletes all the prime ideals beyond $\mathfrak{q}$. Note that this is just the opposite of the quotient $R/\mathfrak{q}$ - here all the ideals below $\mathfrak{q}$ are cut off. That is let $\mathcal{P} := \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{p} \subseteq \mathfrak{q} \text{ or } \mathfrak{q} \subseteq \mathfrak{p} \,\}$ be the set of all prime ideals of R comparable with $\mathfrak{q}$. Then the situation can be illustrated in the following way:

(2.131) Corollary: (viz. 1093)
Let $(R,+,\cdot)$ be a commutative ring and $U \subseteq R$ be a multiplicatively closed subset with $0 \notin U$. Further let us abbreviate by $\star$ any one of the words *integral domain*, *noetherian ring*, *artinian ring*, *UFD*, *PID*, *DKD* or *normal ring*. Then we get the following implication

$$R \text{ is a } \star \quad \Longrightarrow \quad U^{-1}R \text{ is a } \star$$

(2.132) Proposition: (viz. 1090)
Let $(R,+,\cdot)$ be any commutative ring, then we present a couple of useful isomorphies concerning localizations: Fix a multiplicatively closed set $U \subseteq R$ and some point $u \in R$ then we obtain

(i) Nota we will formulate and prove this statement for general polynomial rings $R[t \mid A]$, which will be introduced in (7.10). If you are not familiar with the general concept yet, it suffices to take $R[t \mid A] = R[t]$ of the polynomial ring $R[t]$ (which is the case $A = \mathbb{N}$) for now.

Localisation commutes with going to the polynomial ring: I.e. fix any commutative monoid A and regard the polynomial ring $R[t \mid A]$. Then we find the following isomorphism

$$\begin{array}{rcl} U^{-1}\big(R[t \mid A]\big) & \cong_{\mathrm{r}} & \big(U^{-1}R\big)[t \mid A] \\ \dfrac{f}{u} & \mapsto & \displaystyle\sum_{\alpha \in A} \frac{f[\alpha]}{u} t^{\alpha} \end{array}$$

(ii) Consider $U \subseteq R$ multiplicatively closed and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ any ideal of R such that $U \cap \mathfrak{a} = \emptyset$. Now denote $U/\mathfrak{a} := \{\, u + \mathfrak{a} \mid u \in U \,\}$, then we obtain the following isomorphism

$$\begin{array}{rcl} U^{-1}R \,\big/\, U^{-1}\mathfrak{a} & \cong_{\mathrm{r}} & \Big(U \,\big/\, \mathfrak{a}\Big)^{-1} \Big(R \,\big/\, \mathfrak{a}\Big) \\ \dfrac{b}{v} + U^{-1}\mathfrak{a} & \mapsto & \dfrac{b+\mathfrak{a}}{v+\mathfrak{a}} \end{array}$$

(iii) The localized ring R_u can be gained by picking up a solution t to the equation $ut - 1 = 0$. That is it is just the quotient of the polynomial ring of R by $ut - 1$

$$\begin{array}{rcl} R_u & \cong_{\mathrm{r}} & R[t] \,\big/\, (ut-1)R[t] \\ \dfrac{a}{u^k} & \mapsto & at^k + (ut-1)R[t] \\ f(1/u) & \hookleftarrow & f + (ut-1)R[t] \end{array}$$

(iv) Let $(R,+,\cdot)$ be an integral domain and $0 \notin U \subseteq R$ be a multiplicatively closed subset of R *not* containing 0. Then the quotient fields of R and $U^{-1}R$ are isomorphic under

$$\text{QUOT}(R) \;\cong_{\text{r}}\; \text{QUOT}(U^{-1}R) \;:\; \frac{a}{b} \mapsto \frac{a/1}{b/1}$$

(v) Let $(R,+,\cdot)$ be an integral domain and $0 \neq a, b \in R$ be two non-zero elements of R and let $n \in \mathbb{N}$. Then we obtain the following isomorphism

$$\left(R_a\right)_{b/a^n} \;\cong_{\text{r}}\; R_{ab} \;:\; \frac{x/a^i}{(b/a^n)^j} \mapsto \frac{xa^{(n+1)j}b^i}{(ab)^{i+j}}$$

(vi) In particular: Let $\mathfrak{p} \trianglelefteq_{\text{i}} R$ be a prime ideal and $\mathfrak{a} \trianglelefteq_{\text{i}} R$ be any ideal of R such that $\mathfrak{a} \subseteq \mathfrak{p}$. Then we denote $\mathfrak{a}_\mathfrak{p} := (R \setminus \mathfrak{p})^{-1}\mathfrak{a}$ and thereby obtain the following isomorphy

$$R_\mathfrak{p} \Big/ \mathfrak{a}_\mathfrak{p} \;\cong_{\text{r}}\; \left(R \Big/ \mathfrak{a}\right)_{\mathfrak{p}/\mathfrak{a}} \;:\; \frac{b}{u} + \mathfrak{a}_\mathfrak{p} \mapsto \frac{b+\mathfrak{a}}{u+\mathfrak{a}}$$

(vii) Let $\mathfrak{p} \trianglelefteq_{\text{i}} R$ be a prime ideal of R and denote $\overline{\mathfrak{p}} := (R \setminus \mathfrak{p})^{-1}\mathfrak{p}$. If now $a \notin \mathfrak{p}$ is *not* contained in $\mathfrak{p}$ then we obtain the isomorphy

$$R_\mathfrak{p} \;\cong_{\text{r}}\; (R_a)_{\overline{\mathfrak{p}}} \;:\; \frac{a}{u} \;\mapsto\; \frac{r/1}{u/1}$$

(2.133) Lemma: (viz. 1083)
Local-Global-Principle: Let $(R,+,\cdot)$ be any commutative ring and $a, b \in R$, then we obtain the equivalence of the following statements

$$\begin{aligned} a = b \quad &\iff \quad \forall\, \mathfrak{p} \in \text{Spec}(R) \;:\; \frac{a}{1} = \frac{b}{1} \in R_\mathfrak{p} \\ &\iff \quad \forall\, \mathfrak{m} \in \text{Smax}(R) \;:\; \frac{a}{1} = \frac{b}{1} \in R_\mathfrak{m} \end{aligned}$$

Further if R is an integral domain and $F := \text{QUOT}(R)$ is its quotient field, then we can embed R into F, as $R = \{\, a/1 \in F \mid a \in R \,\}$. Likewise if $\mathfrak{p} \trianglelefteq_{\text{i}} R$ is a prime ideal then we embed the localization into the quotient field F as well, in the form $R_\mathfrak{p} = \{\, a/u \in F \mid a \in R,\; u \notin \mathfrak{p} \,\}$. And thereby we obtain the following identities (as subsets of F)

$$R \;=\; \bigcap_{\mathfrak{p} \in \text{spec}R} R_\mathfrak{p} \;=\; \bigcap_{\mathfrak{m} \in \text{smax}R} R_\mathfrak{m}$$

(2.134) Corollary: (viz. 1100)
Let $(R,+,\cdot)$ be an integral domain and denote its quotient field by $E := \text{QUOT}(R)$. Then the following three statements are equivalent

(a) R is normal

(b) $\forall\, \mathfrak{p} \in \text{Spec}(R) \;:\; R_\mathfrak{p}$ is normal

(c) $\forall\, \mathfrak{m} \in \text{Smax}(R) \;:\; R_\mathfrak{m}$ is normal

2.11 Local Rings

Not surprisingly a local ring is the result of localizing a commutative ring (in a prime ideal). These rings only have a single maximal ideal and this has several very restrictive consequences: Local rings have a very orderly structure. We will also see that external functions (valuations) may also enforce powerful restrictions on the rings internal structure, only allowing local rings.

(2.135) Definition: (viz. 1103)
Let $(R,+,\cdot)$ be any commutative ring, then R is said to be a **local ring**, iff it satisfies one of the following two equivalent properties

(a) R has precisely one maximal ideal (i.e. $\#\operatorname{Smax}(R) = 1$)

(b) the set of non-units is an ideal $R \setminus R^* \trianglelefteq_{\mathrm{i}} R$ in R

Nota In this case the uniquely determined maximal ideal of R is precisely the set of non-units $R \setminus R^*$, which can always be given explicitly as $R \setminus R^* = \{a \in R \mid aR \neq R\} \trianglelefteq_{\mathrm{i}} R$.

(2.136) Proposition: (viz. 1103)
Let $(R,+,\cdot)$ be a commutative ring and $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$ be a proper ideal of R (that is $\mathfrak{m} \neq R$). Then the following four statements are equivalent

(a) R is a local ring with maximal ideal $\mathfrak{m}$

(b) $\forall\, \mathfrak{a} \trianglelefteq_{\mathrm{i}} R \,:\, \mathfrak{a} \neq R \implies \mathfrak{a} \subseteq \mathfrak{m}$

(c) $R \setminus \mathfrak{m} = R^*$

(d) $R \setminus \mathfrak{m} \subseteq R^*$

(2.137) Example:

- If $(F,+,\cdot)$ is a field, then $F \setminus \{0\} = F^*$, in particular F already is a local ring having the maximal ideal $\{0\}$. And of course the converse is true, as well: If $\{0\}$ is a maximal ideal in the commutative ring F, then F is a field.
- Let $(E,+,\cdot)$ be a field and consider the ring of formal power series $R := E[\![t]\!]$ over E. Then $E[\![t]\!]$ is a local ring having the maximal ideal

$$\mathfrak{m} \;:=\; t\,E[\![t]\!] \;=\; \{\, f \in E[\![t]\!] \mid f[0] = 0 \,\}$$

 To prove this it suffices to check $R \setminus \mathfrak{m} \subseteq R^*$ (due to the above proposition (2.136)). But in fact if $f \in E[\![t]\!]$ is any power series with $f[0] \neq 0$ then an elementary computation shows that we can iteratively compute the inverse of f, by

$$\begin{aligned} f^{-1}[0] &= \frac{1}{f[0]} \\ f^{-1}[k] &= \frac{-1}{f[0]} \sum_{j=0}^{k-1} f[k-j] f^{-1}[j] \end{aligned}$$

- Let $(R,+,\cdot)$ be a commutative ring and $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ be any prime ideal of R. Then in (2.138) below we will prove that the localized ring $R_{\mathfrak{p}}$ is a local ring having the maximal ideal

$$\mathfrak{m}_{\mathfrak{p}} \;:=\; (R \setminus \mathfrak{p})^{-1}\mathfrak{p} \;=\; \{\, p/u \mid p \in \mathfrak{p}, u \notin \mathfrak{p} \,\}$$

- If $(R,+,\cdot)$ is a local ring with maximal ideal $\mathfrak{m}$ and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is a proper ideal of R, then the quotient ring $R/\mathfrak{a}$ is a local ring again, with maximal ideal $\mathfrak{m}/\mathfrak{a}$.

 Prob as $\mathfrak{a} \neq R$ we have $\mathfrak{a} \subseteq \mathfrak{m}$, there is a maximal ideal containing $\mathfrak{a}$ by (2.4.(ii)) and $\mathfrak{m}$ is the only maximal ideal, available. Also $\mathrm{Smax}(R/\mathfrak{a})$ corresponds to $\{\, \mathfrak{m} \in \mathrm{Smax}(R) \mid \mathfrak{a} \subseteq \mathfrak{m} \,\} = \{\, \mathfrak{m} \,\}$, according to (1.71). Thus $\mathfrak{m}/\mathfrak{a}$ is the one and only maximal ideal of $R/\mathfrak{a}$.

- Let $(S,+,\cdot)$ be a PID, $1 \leq n \in \mathbb{N}$ and $p \in S$ be a prime element of S. Then we have proved in (2.109.(iii)) that $R := S/p^nS$ is a local ring having the maximal ideal

$$\mathrm{NIL}(R) \;=\; \mathrm{ZD}(R) \;=\; R \setminus R^* \;=\; (p + p^nS)\,R$$

- If $(R,+,\cdot)$ is any commutative ring and $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$ is a maximal ideal of R, then for any power $1 \leq n \in \mathbb{N}$ the ring $S := R/\mathfrak{m}^n$ is local, having the maximal ideal $\mathfrak{m}/\mathfrak{m}^n$.

 Prob Let $\overline{\mathfrak{n}} \trianglelefteq_{\mathrm{i}} S$ be any maximal ideal of S, then this is of the form $\overline{\mathfrak{n}} = \mathfrak{n}/\mathfrak{m}^n$ for some maximal ideal $\mathfrak{n}$ of R with $\mathfrak{m}^n \subseteq \mathfrak{n}$. But as $\mathfrak{n}$ also is prime this implies $\mathfrak{m} \subseteq \mathfrak{n}$ and hence $\mathfrak{n} = \mathfrak{m}$, since $\mathfrak{m}$ is maximal in R, too. Hence the maximal ideal of S is uniquely determined.

- A local ring need not be noetherian: As an example consider the polynomial ring in infinitely many variables $R = E[t_1, t_2, \ldots]$ over a field $(E,+,\cdot)$ and the maximal ideal $\mathfrak{m} := \langle t_1, t_2, \ldots \rangle_{\mathrm{i}} \trianglelefteq_{\mathrm{i}} R$. Then the localization $R_{\mathfrak{m}}$ of R in $\mathfrak{m}$ is a local ring with maximal ideal $\mathfrak{m}R_{\mathfrak{m}}$. According to (2.129) it also contains an infinitely ascending chain of prime ideals however

$$\langle t_1 \rangle_{\mathrm{i}} R_{\mathfrak{m}} \;\subset\; \langle t_1, t_2 \rangle_{\mathrm{i}} R_{\mathfrak{m}} \;\subset\; \langle t_1, t_2, t_3 \rangle_{\mathrm{i}} R_{\mathfrak{m}} \;\subset\; \ldots$$

(2.138) Proposition: (viz. 1103)
Let $(R,+,\cdot)$ be a commutative ring and consider a set $\mathcal{Q} = \{\, \mathfrak{q}_1, \ldots, \mathfrak{q}_n \,\} \subseteq \mathrm{Spec}(R)$ of finitely many prime ideals of R. Let $Q := \mathfrak{q}_1 \cup \cdots \cup \mathfrak{q}_n \subseteq R$ be the union of these ideals and let

$$U \;:=\; R \setminus Q \;=\; \bigcap_{i=1}^{n} (R \setminus \mathfrak{q}_i)$$

Then $U \subseteq R$ is multiplicatively closed such that we can localize $U^{-1}R$. Recall that any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ with $\mathfrak{a} \cap U = \emptyset$ (that is $\mathfrak{a} \subseteq R \setminus P$) corresponds to an ideal

$$\mathfrak{a}\,U^{-1}R \;=\; U^{-1}\mathfrak{a} \;=\; \left\{ \frac{a}{u} \mid a \in \mathfrak{a}, u \in U \right\}$$

of $U^{-1}R$. Now denote the set of all ideals maximal in $\mathcal{Q}$ by $\mathcal{Q}^*$. That is $\mathfrak{m} \in \mathcal{Q}^*$ if and only if $\mathfrak{m} \in \mathcal{Q}$ and for any $\mathfrak{q} \in \mathcal{Q}$ we get $\mathfrak{m} \subseteq \mathfrak{q} \implies \mathfrak{m} = \mathfrak{q}$. Then we can explicitly give the prime and maximal ideals of $U^{-1}R$ to be the following

$$\begin{aligned} \operatorname{Spec}(U^{-1}R) &= \left\{ U^{-1}\mathfrak{p} \;\middle|\; \begin{array}{l} \mathfrak{p} \in \operatorname{Spec}(R) \text{ such that} \\ \exists\, \mathfrak{m} \in \mathcal{Q}^* : \mathfrak{p} \subseteq \mathfrak{m} \end{array} \right\} \\ \operatorname{Smax}(U^{-1}R) &= \left\{ U^{-1}\mathfrak{m} \mid \mathfrak{m} \in \mathcal{Q}^* \right\} \end{aligned}$$

In particular $U^{-1}R$ has finitely many maximal ideals only (such a ring is called *semi-local*). In case $n = 1$, that is $\mathcal{Q} = \{ \mathfrak{p} \}$, of a single prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ the ring $R_{\mathfrak{p}} := (R \setminus \mathfrak{p})^{-1}R$ only has one maximal ideal (such a ring is called *local*). Thereby the maximal ideal of $R_{\mathfrak{p}}$ is given to be

$$\mathfrak{m}_{\mathfrak{p}} := (R \setminus \mathfrak{p})^{-1}\mathfrak{p} = \left\{ \frac{p}{u} \mid p \in \mathfrak{p},\, u \in R \setminus \mathfrak{p} \right\}$$

And the residue field of $R_{\mathfrak{p}}$ modulo $\mathfrak{m}_{\mathfrak{p}}$ is isomorphic to the quotient field of $R/\mathfrak{p}$ under the isomorphism

$$R_{\mathfrak{p}} \Big/ \mathfrak{m}_{\mathfrak{p}} \cong_{\mathrm{f}} \operatorname{QUOT}\left(R \Big/ \mathfrak{p} \right) : \frac{a}{u} + \mathfrak{m}_{\mathfrak{p}} \mapsto \frac{a + \mathfrak{p}}{u + \mathfrak{p}}$$

(2.139) Proposition: (viz. 1104)
Let $(R, +, \cdot)$ be a local ring with maximal ideal $\mathfrak{m}$ and let $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be any ideal of R. Then the following four statements are equivalent

(a) $\sqrt{\mathfrak{a}} = \mathfrak{m}$

(b) $\mathfrak{a}$ is $\mathfrak{m}$-primary

(c) $\mathfrak{m}$ is a minimal prime ideal over $\mathfrak{a}$

(d) $\mathfrak{m}$ is the only prime ideal containing $\mathfrak{a}$, i.e. $\mathbb{V}(\mathfrak{a}) = \{ \mathfrak{m} \}$

Discrete Valuation Rings

(2.140) Definition:
Let $(R, +, \cdot)$ be any non-zero (i.e. $R \neq 0$), commutative ring, then a mapping $\nu : R \to \mathbb{N} \cup \{\infty\}$ is said to be a **valuation** (and the ordered pair (R, ν) a **valued ring**) iff for any $a, b \in R$ we obtain the following three properties

(1) $\nu(a) = \infty \iff a = 0$

(2) $\nu(ab) = \nu(a) + \nu(b)$

(3) $\nu(a + b) \geq \min\{ \nu(a), \nu(b) \}$

And a valuation ν is said to be **normed** iff it further satisfies the following fourth property

(N) $\exists\, a \in R : \nu(a) = 1$

(2.141) Remark:
So what is the connection between local rings and valuations? In fact, it is readily apparent that the maximal ideal $\mathfrak{m}$ of a local ring R constitutes a map ν of the form $\nu : R \to \mathbb{N} \cup \{\infty\}$, that inspired the definition of a valuation, namely

$$\nu(a) \;:=\; \sup\{k \in \mathbb{N} \mid a \in \mathfrak{m}^k\}$$

This map satisfies $\nu(0) = \infty$, $\nu(ab) \geq \nu(a) + \nu(b)$ and $\nu(a+b) \geq \min\{\nu(a), \nu(b)\}$ for any ideal $\mathfrak{m}$. In a local ring we also have $R^* = [\nu] := \{a \in R \mid \nu(a) = 0\}$. In general ν need not be a valuation, we will require further properties for this.

Prob Clearly $0 \in \mathfrak{m}^k$ for any $k \in \mathbb{N}$ and hence $\nu(0) = \infty$. Also if $\nu(a) = j$ and $\nu(b) = k$ then $a \in \mathfrak{m}^j$ and $b \in \mathfrak{m}^k$ and therefore $ab \in \mathfrak{m}^{j+k}$ which is $\nu(ab) \geq j + k$. Without loss of generality assume $j \leq k$, then $b \in \mathfrak{m}^k \subseteq \mathfrak{m}^j$ and hence $a + b \in \mathfrak{m}^j$ again, hence $\nu(a+b) \geq j$. Finally $\nu(a) = 0$ iff $a \in R \setminus \mathfrak{m} = R^*$.

(2.142) Proposition: (viz. 1104)

(i) Let (R, ν) be a valued ring (in particular $R \neq 0$), then R and its valuation ν already satisfy the following additional properties

(U) $a \in R^* \implies \nu(a) = 0$

(I) R is an integral domain

(P) $[\nu] := \{a \in R \mid \nu(a) \geq 1\} \in \mathrm{Spec}(R)$

(ii) If $(R, +, \cdot)$ is a non-zero integral domain then R always carries the **trivial valuation** which we denote by $\tau : R \to \mathbb{N} \cup \{\infty\}$ and which is defined by $\tau(a) := 0$ iff $a \neq 0$ and $\tau(a) := \infty$ iff $a = 0$. Note that this valuation is *not* normed, of course.

(iii) Let $(R, +, \cdot)$ be a noetherian integral domain and consider any $p \in R$ prime. Then we obtain a normed valuation $\nu = \nu_p$ on R that satisfies $\nu(p) = 1$ and $[\nu] = pR$, by letting

$$\nu \;:\; R \to \mathbb{N} \cup \{\infty\} \;:\; a \mapsto [a]_p$$

$$\text{where} \quad [a]_p \;:=\; \sup\Big\{ k \in \mathbb{N} \mid p^k \mid a \Big\}$$

And for any $a, b \in R$ this valuation satisfies a fifth property, namely we also get the implication

$$\nu(a) \neq \nu(b) \quad \Longrightarrow \quad \nu(a+b) = \min\{\nu(a), \nu(b)\}$$

(iv) Let $(R, +, \cdot)$ be a PID then we obtain a one-to-one correspondence between the maximal spectrum of R and the normed valuations on R, using the construction in (iii)

$$\begin{array}{rcl} \mathrm{Smax}(R) & \longleftrightarrow & \{\nu : R \to \mathbb{N} \cup \{\infty\} \mid (1), (2), (3), (N)\} \\ \mathfrak{m} & \mapsto & \nu_p \text{ where } \mathfrak{m} = pR \\ [\nu] & \hookleftarrow & \nu \end{array}$$

(2.143) Remark:
In a polynomial ring, do not confuse valuations with degrees. E.g. in the polynomial ring $R = \mathbb{Z}[t]$ the degree is the highest power $\deg(f) = n$ occurring in the polynomial $f(t) = a_n t^n + \cdots + a_1 t + a_0$. Hence the degree is bounded from above $\deg(f+g) \leq \max\{\deg(f), \deg(g)\}$.
Taking to $p = t \in R$ the valuation ν_t is the lowest power occurring in a polynomial f. That is: If $f \in R[t]$ is of the form $f(t) = a_n t^n + \cdots + a_m t^m$ with $a_n \neq 0$ and $a_m \neq 0$, but all coefficients $f[k] = 0$ for $k \notin m \ldots n$, then $\deg(f) = n$ and $\nu_t(f) = m$. Therefore the valuation ν_t is bounded from below $\nu_t(f+g) \geq \min\{\nu_t(f), \nu_t(g)\}$. So generally speaking the one and only common property of degrees and valuations is multiplicativity. Apart from that they are similar but separate concepts.

(2.144) Definition:
Let $(R, +, \cdot)$ be a commutative ring, then we call $\nu : R \to \mathbb{N} \cup \{\infty\}$ a **discrete valuation** on R (and the ordered pair (R, ν) is said to be a **discrete valuation ring**), iff ν satisfies all of the following properties (for any a, $b \in R$)

(1) $\nu(a) = \infty \iff a = 0$

(2) $\nu(ab) = \nu(a) + \nu(b)$

(3) $\nu(a+b) \geq \min\{\nu(a), \nu(b)\}$

(4) $\nu(a) \leq \nu(b) \implies a \mid b$

(N) $\exists\, m \in R : \nu(m) = 1$

(2.145) Example:

- The prototype of a discrete valuation ring is the ring of formal power series $E[\![t]\!]$ over a field E. And in this case we obtain a discrete valuation ν (note that $[\nu] = tE[\![t]\!]$), by
$$\nu : E[\![t]\!] \to \mathbb{N} \cup \{\infty\} : f \mapsto \sup\left\{ k \in \mathbb{N} \mid t^k \mid f \right\}$$
- We regard $F = \mathbb{Q}$ and fix any prime number $p \in \mathbb{Z}$. Then we obtain a discrete valuation ν_p in the sense of (2.146.(vi)) on the field $\mathbb{Q}$ by letting $\nu_p : \mathbb{Q} \to \mathbb{Z} \cup \{\infty\}$ (where a, $b \in \mathbb{Z}$, $b \neq 0$)
$$\nu_p\left(\frac{a}{b}\right) := [a]_p - [b]_p$$
$$[a]_p := \sup\left\{ k \in \mathbb{N} \mid p^k \mid a \right\}$$
Thereby ν_p is said to be the *p-adic valuation* of $\mathbb{Q}$. And if we denote $\mathfrak{p} := p\mathbb{Z}$, then the discrete valuation ring determined by ν_p is just $\{a \in \mathbb{Q} \mid \nu_p(a) \geq 0\} \cong_r \mathbb{Z}_{\mathfrak{p}}$ canonically.
- More generally the above construction works out for any PID R: Let F be the quotient field of R and $p \in R$ be any prime element. Then we may repeat the definition of ν_p literally (except for a, $b \in R$) and thereby obtain a discrete valuation $\nu_p : F \to \mathbb{Z} \cup \{\infty\}$. And the discrete valuation ring determined by ν_p is $R_{\mathfrak{p}}$ (where $\mathfrak{p} := pR$) again.

(2.146) Proposition: (viz. 1105)
Let (R,ν) be a discrete valuation ring, in particular $\nu : R \to \mathbb{N} \cup \{\infty\}$, then R and its valuation ν already satisfy all of the following additional properties

(i) (R,ν) is a valued ring, in particular R is a non-zero integral domain.

(ii) R is a local ring with maximal ideal $[\nu] = \{a \in R \mid \nu(a) \geq 1\}$.

(iii) (R,ε) is an Euclidean domain under $\varepsilon : R \setminus \{0\} \mapsto \mathbb{N} : a \mapsto \nu(a)$.

(iv) Fix any $m \in R$ with $\nu(m) = 1$, then for any $0 \neq a \in R$ there is a uniquely determined unit $\alpha \in R^*$ such that $a = \alpha m^k$ for $k = \nu(a)$.

(v) Fix any $m \in R$ with $\nu(m) = 1$ again, as R is a PID and m divides any $a \neq 0$ with $\nu(a) \geq 1$, we find that the set of ideals of R is given to be the following

$$\mathsf{Ideal}(R) \;=\; \left\{ m^k R \;\middle|\; k \in \mathbb{N} \right\} \cup \{0\}$$

(vi) Let $(F,+,\cdot)$ be an arbitrary field and $\nu : F \to \mathbb{Z} \cup \{\infty\}$ be a discrete valuation except for the void divisibility condition (4). That is ν satisfies the following four properties (for any $x, y \in F$)

(1) $\nu(x) = \infty \iff x = 0$
(2) $\nu(xy) \;=\; \nu(x) + \nu(y)$
(3) $\nu(x+y) \;\geq\; \min\{\, \nu(x), \nu(y) \,\}$
(N) $\exists\, m \in F \;:\; \nu(m) = 1$

Then we obtain a sub-ring R of F by letting $R := \{a \in F \mid \nu(a) \geq 0\} \;\leq_{\mathsf{r}}\; F$. Also $\nu : R \to \mathbb{N} \cup \{\infty\}$ is a discrete valuation on R and finally F is the quotient field of R, that is we get

$$F \;=\; \left\{ ab^{-1} \mid a,b \in F,\; b \neq 0 \right\}$$

(2.147) Theorem: (viz. 1106)
A commutative ring $(R,+,\cdot)$ is said to be a **discrete valuation ring** (abbreviated by DVR), iff it satisfies one of the following six equivalent properties

(a) R admits a discrete valuation $\nu : R \to \mathbb{N} \cup \{\infty\}$

(b) R is an integral domain and there is some element $0 \neq m \in R$ satisfying

$$R \setminus mR = R^* \quad \text{and} \quad \bigcap_{k \in \mathbb{N}} m^k R = 0$$

(c) R is a PID and local ring but not a field.

(d) R is an UFD but no field and any two prime elements of R are associates (i.e. if $p, q \in R$ are irreducible, then we get $pR = qR$).

(e) R is a noetherian integral domain and local ring, whose maximal ideal $\mathfrak{m}$ is a non-zero principal ideal (i.e. $\mathfrak{m} = mR$ for some $0 \neq m \in R$).

(f) R is a noetherian, normal and local ring with non-zero maximal ideal $\mathfrak{m} \neq 0$ and the only prime ideals of R are 0 and $\mathfrak{m}$ (i.e. $\mathrm{Spec}(R) = \{0, \mathfrak{m}\}$).

(2.148) Definition:
A commutative ring $(R, +, \cdot)$ is said to be a **valuation ring**, iff it is a non-zero integral domain in which the *divides* relation is a total order. Formally that is, iff R satisfies the following three properties

(1) $R \neq 0$

(2) R is an integral domain

(3) $\forall\, a, b \in R$ we get $a \mid b$ or $b \mid a$

(2.149) Remark:
The last property (3) in the definition above might seem a little artificial. We hence wish to explain where it comes from: As R is an integral domain we may regard its quotient field $E := \mathrm{QUOT}(R)$. Then property (3) can be reformulated, as

$$\forall\, x \in E \setminus \{0\} \quad : \quad x \in R \text{ or } x^{-1} \in R$$

Thus if we are given a valuation (in the sense of fields) $\nu : E \to \mathbb{Z} \cup \{0\}$ on E, we may regard the sub-ring $R := \{a \in E \mid \nu(a) \geq 0\}$. And it is clear that R satisfies the property $x \in R$ or $x^{-1} \in R$ for any $0 \neq x \in E$. Thus every ν is assigned a valuation ring R in E. Therefore valuation rings appear naturally whenever we regard valuations on fields.

(2.150) Corollary: (viz. 1108)

(i) If $(R, +, \cdot)$ is a valuation ring, then R already is a local ring and Bezout domain (that is any finitely generated ideal already is principal).

(ii) If $(R, +, \cdot)$ is a valuation ring, then we get the following equivalences

(a) R is noetherian

(b) R is a PID

(c) R is a DVR or field

2.12 Dedekind Domains

Prime factorization of elements of a ring (preferably an UFD) is a powerful tool in algebra, however it is available in very tame rings, such as PIDs or polynomial rings over a field. We have already studied Lasker-Noether theory of decomposition of an ideal into primary ideals. What follows is something in between: Factorization of ideals into prime ideals, just like primary decomposition of elements. Though this has somewhat nicer properties than Lasker-Noether decomposition, the price is more strict requirements of the underlying ring. In the end this is a beautiful theory that has some applications in algebraic number theory:

(2.151) Definition:
Let $(R,+,\cdot)$ be an integral domain and let us denote its quotient field by $F := \mathrm{QUOT}(R)$. Then a subset $\mathfrak{f} \subseteq F$ is called a **fraction ideal** of R (which we abbreviate by writing $\mathfrak{f} \trianglelefteq_{\mathfrak{f}} R$) iff it satisfies

(1) $\mathfrak{f} \leq_{\mathfrak{m}} F$ is an R-sub-module of F

(2) $\exists\, 0 \neq r \in R$ such that $r\mathfrak{f} \subseteq R$

(2.152) Remark:

- In particular any ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ is a fraction ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{f}} R$ (Prob just let $r = 1$). By abuse of nomenclature ordinary ideals of R are hence also said to be the *integral ideals* of F.
- Conversely for any fraction ideal $\mathfrak{f} \trianglelefteq_{\mathfrak{f}} R$ we see that $\mathfrak{f} \cap R \trianglelefteq_{\mathfrak{i}} R$ is an ideal of R. Prob because $0 \in \mathfrak{f} \cap R$ and looking at some $f, g \in \mathfrak{f}$ and $a \in R$ we clearly get $f + g \in \mathfrak{f} \cap R$ and $af \in \mathfrak{f} \cap R$ as both, $\mathfrak{f}$ and R are R-modules.
- And clearly for any $x \in F$ the generated module $\mathfrak{f} := xR$ is a fraction ideal $\mathfrak{f} \trianglelefteq_{\mathfrak{f}} R$ of R Prob because if $x = r/s$ then obviously $s\mathfrak{f} = rR \subseteq R$.
- If R itself is a field, then $F = R$ and the only possible fraction ideals of R are 0 and R itself. Prob suppose there was some $x \neq 0$ such that $x \in \mathfrak{f} \trianglelefteq_{\mathfrak{f}} R$, then x has an inverse $x^{-1} \in R$ and hence $1 = x^{-1}x \in \mathfrak{f}$. Thus for any $a \in R$ we have $a = a1 \in \mathfrak{f}$.

(2.153) Proposition: (viz. 1109)
Let $(R,+,\cdot)$ be an integral domain and let us denote its quotient field by $F := \mathrm{QUOT}(R)$. As in the case of integral ideals, if $\mathfrak{f}$ and $\mathfrak{g} \trianglelefteq_{\mathfrak{f}} R$ are fraction ideals of R, then the sum $\mathfrak{f}+\mathfrak{g}$, intersection $\mathfrak{f}\cap\mathfrak{g}$ and product $\mathfrak{f}\mathfrak{g}$ of finitely many fraction ideals is a fraction ideal again. And if $\mathfrak{g} \neq 0$ we may also define the quotient $\mathfrak{f} : \mathfrak{g}$ of two fraction ideals. I.e. if $\mathfrak{f}$ and $\mathfrak{g} \trianglelefteq_{\mathfrak{f}} R$ are fraction ideals of R then we obtain further fraction ideals of R by letting

$$\begin{aligned} \mathfrak{f}+\mathfrak{g} &:= \{\, x+y \mid x \in \mathfrak{f}, y \in \mathfrak{g} \,\} \\ \mathfrak{f}\cap\mathfrak{g} &:= \{\, x \mid x \in \mathfrak{f} \text{ and } x \in \mathfrak{g} \,\} \\ \mathfrak{f}:\mathfrak{g} &:= \{\, x \in F \mid x\mathfrak{g} \subseteq \mathfrak{f} \,\} \end{aligned}$$

$$\mathfrak{f}\mathfrak{g} := \left\{ \sum_{i=1}^{n} f_i g_i \;\middle|\; n \in \mathbb{N}, f_i \in \mathfrak{f}, g_i \in \mathfrak{g} \right\}$$

(2.154) Remark:

- Let now $0 \neq \mathfrak{f}$ and $\mathfrak{g} \trianglelefteq_{\mathfrak{f}} R$ be two non-zero fraction ideals of the integral domain $(R, +, \cdot)$ and let $F = \mathrm{QUOT}(R)$. Then the product $\mathfrak{f}\mathfrak{g}$ and quotient $\mathfrak{f} : \mathfrak{g} \neq 0$ are non-zero, too. Formally that is

$$\mathfrak{f}, \mathfrak{g} \neq 0 \quad \Longrightarrow \quad \mathfrak{f}\mathfrak{g} \neq 0 \text{ and } \mathfrak{f} : \mathfrak{g} \neq 0$$

 Prob as $\mathfrak{f}$ and $\mathfrak{g} \neq 0$ we may choose some $0 \neq f \in \mathfrak{f}$ and $0 \neq g \in \mathfrak{g}$. Then $fg \in \mathfrak{f}\mathfrak{g}$ and $fg \neq 0$, as F is an integral domain (yielding $\mathfrak{f}\mathfrak{g} \neq 0$). Now let $s\,\mathfrak{g} \subseteq R$ for some $s \neq 0$. Then $(sf)\mathfrak{g} = f(s\,\mathfrak{g}) \subseteq fR \subseteq \mathfrak{f}$ and hence $sf \in \mathfrak{f} : \mathfrak{g}$. But as $sf \neq 0$ this means $\mathfrak{f} : \mathfrak{g} \neq 0$.

- For any fraction ideal $\mathfrak{f} \trianglelefteq_{\mathfrak{f}} R$ we always get the inclusions: $\mathfrak{f}(R : \mathfrak{f}) \subseteq R \subseteq \mathfrak{f} : \mathfrak{f}$.

 Prob $\mathfrak{f}(R : \mathfrak{f})$ contains elements of the form $x_1y_1 + \cdots + x_ny_n$ where $x_i \in R : \mathfrak{f}$ and $y_i \in \mathfrak{f}$. But by definition of $R : \mathfrak{f}$ this means $x_iy_i \in R$ and hence $x_1y_1 + \cdots + x_ny_n \in R$. And $R \subseteq \mathfrak{f} : \mathfrak{f}$ is clear, as $\mathfrak{f} \leq_{\mathfrak{m}} F$ such that $ay \in \mathfrak{f}$ for any $a \in R$ and $y \in \mathfrak{f}$.

- First note that the multiplication $\mathfrak{f}\mathfrak{g}$ of fraction ideals is both commutative and associative. Further it is clear that for any fraction ideal $\mathfrak{f} \trianglelefteq_{\mathfrak{f}} R$ we get $R\mathfrak{f} = \mathfrak{f}$. That is the set of fraction ideals of R is a commutative monoid under the multiplication (defined in (2.153)) with neutral element R. This naturally leads to the definition of an *invertible* fraction ideal. Of course the non-zero fraction ideals als form a monoid and this is called the *class monoid* of R, denoted by

$$\mathcal{C}(R) \;:=\; \{\, \mathfrak{f} \trianglelefteq_{\mathfrak{f}} R \mid \mathfrak{f} \neq 0 \,\}$$

(2.155) Definition: (viz. 1109)
Let $(R, +, \cdot)$ be an integral domain and let us denote its quotient field by $F := \mathrm{QUOT}(R)$. Then a fraction ideal $\mathfrak{f} \trianglelefteq_{\mathfrak{f}} R$ of R is said to be **invertible**, iff it satisfies one of the following two equivalent conditions

(a) $\exists\, \mathfrak{g} \trianglelefteq_{\mathfrak{f}} R \;:\; \mathfrak{f}\mathfrak{g} = R$

(b) $\mathfrak{f}(R : \mathfrak{f}) \;=\; R$

Note that in this case the fraction ideal $\mathfrak{g}$ with $\mathfrak{f}\mathfrak{g} = R$ is uniquely determined, to be $\mathfrak{g} = R : \mathfrak{f}$. And it is called the **inverse** of $\mathfrak{f}$, written as

$$\mathfrak{f}^{-1} \;:=\; \mathfrak{g} \;=\; R : \mathfrak{f}$$

(2.156) Proposition: (viz. 1109)
Let $(R, +, \cdot)$ be an integral domain and let us denote its quotient field by $F := \mathrm{QUOT}(R)$ again. If now $0 \neq \mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ is a non-zero ideal of R, then the following statements are equivalent

(a) $\mathfrak{a}$ is invertible (as a fraction ideal of R), i.e. $\mathfrak{a}\,\mathfrak{g} = R$ for a suitable fraction ideal $\mathfrak{g} \trianglelefteq_{\mathfrak{f}} R$ of R.

(b) There are some $a_1, \ldots a_n \in \mathfrak{a}$ and $x_1, \ldots, x_n \in F$ such that for any $i \in 1 \ldots n$ we get $x_i\,\mathfrak{a} \subseteq R$ and $a_1x_1 + \cdots + a_nx_n = 1$.

(c) $\mathfrak{a}$ is a projective R-module, i.e. there is a free R-module M and a sub-module $P \leq_{\mathfrak{m}} M$ such that M is a direct sum featuring $\mathfrak{a} \oplus P = M$.

(2.157) Corollary: (viz. 1110)
Let $(R,+,\cdot)$ be a local ring, that also is an integral domain. If now $0 \neq \mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ is a non-zero ideal of R then the following statements are equivalent

(a) $\mathfrak{a}$ is a principal ideal (i.e. $\mathfrak{a} = aR$ for some $a \in R$)

(b) $\mathfrak{a}$ is invertible (as a fraction ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{f}} R$)

(2.158) Remark:

- If aR is any non-zero ($a \neq 0$) principal ideal in an integral domain $(R,+,\cdot)$, then $aR \trianglelefteq_{\mathfrak{f}} R$ is an invertible fraction ideal of R. This is clear as its inverse obviously given by

$$\Big(aR\Big)^{-1} \;=\; \frac{1}{a}R$$

- Now consider an (integral) ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ and elements $a_1,\ldots,a_n \in \mathfrak{a}$ and $x_1,\ldots,x_n \in R : \mathfrak{a} \subseteq F$ such that $a_1x_1 + \cdots + a_nx_n = 1$. Then $\mathfrak{a}$ is already generated by the a_i, formally that is

$$\mathfrak{a} \;=\; \langle a_1,\ldots,a_n\rangle_{\mathfrak{i}}$$

 Prob the inclusion " $\supseteq$ " is clear, as $a_i \in \mathfrak{a}$. For the converse inclusion we consider any $a \in \mathfrak{a}$. As $x_i \in R : \mathfrak{a}$ we in particular have $x_i\mathfrak{a} \subseteq R$. And because of $a_1x_1 + \cdots + a_nx_n = 1$ we are able to write a in the form $a = (x_1a)a_1 + \cdots + (x_na)a_n \in \langle a_1,\ldots,a_n\rangle_{\mathfrak{i}}$.

- We have seen in the proposition above, that an (integral) ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ is invertible if and only if there are $a_1,\ldots,a_n \in \mathfrak{a}$ and $x_1,\ldots,x_n \in F$ such that for any $i \in 1\ldots n$ we get

$$x_i\,\mathfrak{a} \in R \quad\text{and}\quad a_1x_1 + \cdots + a_nx_n = 1$$

 Nota as we have just seen this already implies, that the a_i generate $\mathfrak{a}$. Hence any invertible ideal already is finitely generated!

- Now consider some multiplicatively closed subset $0 \notin U \subseteq R$. Then $F = \textsc{quot}(R) = \textsc{quot}(U^{-1}R)$ are canonically isomorphic, by (2.132.(iii)). If now $\mathfrak{f}$ and $\mathfrak{g} \trianglelefteq_{\mathfrak{f}} R$ are any two fraction ideals of R then it is easy to see that $U^{-1}\mathfrak{f} := \{\, a/ub \mid a/b \in \mathfrak{f}, u \in U \,\} \trianglelefteq_{\mathfrak{f}} U^{-1}R$ is a fraction ideal of $U^{-1}R$ and a straightforward computation shows that

$$\Big(U^{-1}\mathfrak{f}\Big)\Big(U^{-1}\mathfrak{g}\Big) \;=\; U^{-1}(\mathfrak{f}\,\mathfrak{g})$$

 In particular if $\mathfrak{f} \trianglelefteq_{\mathfrak{f}} R$ is invertible (over R) then $U^{-1}\mathfrak{f}$ is invertible (over $U^{-1}R$) and vice versa. Formally that is the equivalence

$$\mathfrak{f} \trianglelefteq_{\mathfrak{f}} R \text{ invertible} \quad\Longleftrightarrow\quad U^{-1}\mathfrak{f} \trianglelefteq_{\mathfrak{f}} U^{-1}R \text{ invertible}$$

Prob $(U^{-1}\mathfrak{f})\,(U^{-1}\mathfrak{g})$ is generated by elements of the form $(a/ub)(c/vd)$ where $a/b \in \mathfrak{f}$, $c/d \in \mathfrak{g}$ and u, $v \in U$. Now $uv \in U$ and $(a/ub)(c/vd) = (ac)/(uvbd)$ such that this is contained in $U^{-1}(\mathfrak{f}\,\mathfrak{g})$ again. This proves "$\subseteq$" conversely let $a/b \in \mathfrak{f}$, $c/d \in \mathfrak{g}$ and $u \in U$. Then $U^{-1}(\mathfrak{f}\,\mathfrak{g})$ is generated by elements of the form $(ac)/(ubd)$. And as $(ac)/(ubd) = (a/ub)(c/d)$ this is also contained in $(U^{-1}\mathfrak{f})\,(U^{-1}\mathfrak{g})$. This proves the converse inclusion "$\supseteq$" and hence the equality. And from this equality it is clear that $(U^{-1}\mathfrak{f})^{-1} = U^{-1}(\mathfrak{f}^{-1})$ for invertible fraction ideals (and hence the equivalence).

(2.159) Definition: (viz. 1111)
Let $(R,+,\cdot)$ be an integral domain and let us denote its quotient field by $F := \mathrm{QUOT}(R)$. Then R is said to be a **Dedekind domain** (shortly DKD) iff it satisfies one of the following equivalent statements

(a) every non-zero fraction ideal $0 \neq \mathfrak{f} \trianglelefteq_{\mathrm{f}} R$ is invertible (i.e. there is some fraction ideal $\mathfrak{g} \trianglelefteq_{\mathrm{f}} R$ such that $\mathfrak{f}\,\mathfrak{g} = R$).

(b) every non-zero (integral) ideal $0 \neq \mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is invertible, (i.e. there is some fraction ideal $\mathfrak{g} \trianglelefteq_{\mathrm{f}} R$ such that $\mathfrak{a}\,\mathfrak{g} = R$).

(c) every (integral) ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ with $\mathfrak{a} \notin \{0, R\}$ allows a decomposition into finitely many prime ideals, i.e. $\exists\, \mathfrak{p}_1, \ldots, \mathfrak{p}_n \in \mathrm{Spec}(R)$ such that $\mathfrak{a} = \mathfrak{p}_1 \ldots \mathfrak{p}_n$.

(d) R is a notherian, normal ring in which every non-zero prime ideal already is maximal, the latter being $\mathrm{Spec}(R) = \mathrm{Smax}(R) \cup \{0\}$.

(e) R is noetherian and for any non-zero prime ideal $0 \neq \mathfrak{p} \in \mathrm{Spec}(R)$ the localization $R_{\mathfrak{p}}$ is a discrete valuation ring (i.e. a local PID).

(2.160) Example:
In particular any PID $(R,+,\cdot)$ is a Dedekind domain - it is noetherian, as any ideal even has only one generator, it is normal (as it is an UFD by the fundamental theorem of arithmetic) and non-zero prime ideals are maximal (which can be seen using generators of the ideals).

(2.161) Theorem: (viz. 1116)
Let $(R,+,\cdot)$ be a Dedekind domain and $0 \neq \mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be a non-zero ideal of R. Then R already satisfies an extensive list of further properties, namely

(i) R is noetherian and every non-zero prime ideal of R already is maximal, the latter being

$$\mathrm{Spec}(R) \;=\; \mathrm{Smax}(R) \cup \{0\}$$

(ii) Any ideal $0 \neq \mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ admits a decomposition into finitely many (up to permutations) uniquely determined prime ideals, formally this is

$$\exists!\; \mathfrak{p}_1, \ldots, \mathfrak{p}_n \in \mathrm{Spec}(R) \setminus \{0\} \quad \text{such that} \quad \mathfrak{a} = \mathfrak{p}_1 \ldots \mathfrak{p}_n$$

(iii) For any ideal $0 \neq \mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ the quotient ring $R/\mathfrak{a}$ is a principal ring (i.e. a ring in which any ideal is generated by a single element).

(iv) Any ideal of R can be generated by two elements already, we even get the slightly stronger property

$$\forall\, 0 \neq a \in \mathfrak{a} \;\; \exists\, b \in \mathfrak{a} \quad \text{such that} \quad \mathfrak{a} = aR + bR$$

(v) If R also is semilocal (i.e. R only has finitely many maximal ideals) then R already is a PID (i.e. every ideal is a principal ideal).

(vi) If $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$ is a maximal ideal of R and $1 \leq k \in \mathbb{N}$ then we obtain the following isomorphy of rings (where as usual $R_{\mathfrak{m}} = (R \setminus \mathfrak{m})^{-1}R$ and $\mathfrak{m}^k R_{\mathfrak{m}} = (R \setminus \mathfrak{m})^{-1}\mathfrak{m}^k \trianglelefteq_{\mathrm{i}} R_{\mathfrak{m}}$ denote the localization of R resp. the ideal corresponding to $\mathfrak{m}^k$)

$$R \Big/ \mathfrak{m}^k \;\cong_{\mathrm{r}}\; R_{\mathfrak{m}} \Big/ \mathfrak{m}^k R_{\mathfrak{m}} \;\; : \;\; a + \mathfrak{m}^k \mapsto \frac{a}{1} + \mathfrak{m}^k R_{\mathfrak{m}}$$

(2.162) Definition: (viz. 1114)
Let $(R, +, \cdot)$ be a Dedekind domain, $\mathfrak{m} \in \mathrm{Smax}(R)$ be a maximal ideal and $0 \neq \mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be a non-zero ideal of R. Then we define the **valuation** $\nu_{\mathfrak{m}}$ induced by $\mathfrak{m}$ on the set of ideals of R, by

$$\begin{aligned} \nu_{\mathfrak{m}} \;&:\; \mathrm{Ideal}(R) \to \mathbb{N} \\ &:\; \mathfrak{a} \mapsto \max\Big\{ k \in \mathbb{N} \mid \mathfrak{a} \subseteq \mathfrak{m}^k \Big\} \\ &:\; 0 \mapsto 0 \end{aligned}$$

And for any $a \in R$ we denote $\nu_{\mathfrak{m}}(a) := \nu_{\mathfrak{m}}(aR) \in \mathbb{N}$. Let now $\mathfrak{a}, \mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ be arbitrary ideals of R. The we say that $\mathfrak{b}$ *divides* $\mathfrak{a}$, written as $\mathfrak{b} \mid \mathfrak{a}$, iff it satisfies one of the following equivalent properties:

$$\begin{aligned} \mathfrak{b} \mid \mathfrak{a} \quad &:\Longleftrightarrow \quad \exists\, \mathfrak{c} \trianglelefteq_{\mathrm{i}} R \;:\; \mathfrak{a} = \mathfrak{b}\mathfrak{c} \\ &\Longleftrightarrow \quad \mathfrak{a} \subseteq \mathfrak{b} \\ &\Longleftrightarrow \quad \forall\, \mathfrak{m} \in \mathrm{Smax}(R) \;:\; \nu_{\mathfrak{m}}(\mathfrak{b}) \leq \nu_{\mathfrak{m}}(\mathfrak{a}) \end{aligned}$$

(2.163) Proposition: (viz. 1114)
Let $(R, +, \cdot)$ be a Dedekind domain with quotient field $F := \mathrm{quot}(R)$. And let $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R$ be any maximal (here this is non-zero prime) ideal of R. Then we obtain the following statements:

(i) Consider $\mathcal{M} = \{ \mathfrak{m}_1, \ldots, \mathfrak{m}_n \} \subseteq \mathrm{Smax}(R)$ a finite collection of maximal ideals and for each ideal some power $k(1), \ldots, k(n) \in \mathbb{N}$. Then for any $\mathfrak{m} \in \mathrm{Smax}(R)$ we obtain

$$\nu_{\mathfrak{m}}\left(\mathfrak{m}_1^{k(1)} \ldots \mathfrak{m}_n^{k(n)}\right) \;=\; \begin{cases} k(i) \text{ if } \mathfrak{m} = \mathfrak{m}_i \\ 0 \text{ if } \mathfrak{m} \notin \mathcal{M} \end{cases}$$

(ii) Consider any two non-zero ideals $0 \neq \mathfrak{a}, \mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ then the multiplicity function $\nu_{\mathfrak{m}}$ acts additively under multiplication of ideals, that is

$$\nu_{\mathfrak{m}}(\mathfrak{a}\,\mathfrak{b}) \;=\; \nu_{\mathfrak{m}}(\mathfrak{a}) + \nu_{\mathfrak{m}}(\mathfrak{b})$$

(iii) Let $0 \neq \mathfrak{a}$, $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ be any two non-zero ideals of R and decompose $\mathfrak{a} = \mathfrak{m}_1^{k(1)} \dots \mathfrak{m}_n^{k(n)}$ and $\mathfrak{b} = \mathfrak{m}_1^{l(1)} \dots \mathfrak{m}_n^{l(n)}$ with pairwise distinct maximal ideals $\mathfrak{m}_i \in \mathrm{Smax}(R)$ and $k(i), l(i) \in \mathbb{N}$ (note that this can always be established, as $k(i) = 0$ and $l(i) = 0$ is allowed). Then we get

$$\mathfrak{a} + \mathfrak{b} \;=\; \mathfrak{m}_1^{m(1)} \dots \mathfrak{m}_n^{m(n)} \quad \text{where} \quad m(i) := \min\{\, k(i), l(i) \,\}$$

(iv) Consider any non-zero ideal $0 \neq \mathfrak{a} \trianglelefteq_{\mathrm{i}} R$, as before we decompose $\mathfrak{a}$ into $\mathfrak{a} = \mathfrak{m}_1^{k(1)} \dots \mathfrak{m}_n^{k(n)}$ (with pairwise distinct $\mathfrak{m}_i \in \mathrm{Smax}(R)$ and $1 \leq k(i) \in \mathbb{N}$). Then we obtain *Chinese remainder theorem*:

$$R \Big/ \mathfrak{a} \;\cong_{\mathrm{r}}\; \bigoplus_{i=1}^{n} R \Big/ \mathfrak{m}_i^{k(i)} \;:\; b + \mathfrak{a} \mapsto \left(b + \mathfrak{m}_i^{k(i)} \right)$$

(v) Let $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be any ideal in R, then there is some ideal $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ such that $\mathfrak{a} + \mathfrak{b} = R$ are coprime and $\mathfrak{a}\,\mathfrak{b}$ is principal (i.e. $\exists\, a \in R : \mathfrak{a}\,\mathfrak{b} = aR$).

2.13 Goldman Domains

This section should be skipped at a first exposition to the theory. Though it is not too far flung, it requires several concepts of ring extensions and Krull dimension that will be introduced in the chapters on module theory and ring extensions, only. Also the types of rings we are about to study here (Goldman domains, Hilbert rings and Jacobson rings) are rather restrictive and specific, it is rare to encounter these properties "in the field". However these rings contain the answer to several seemingly innocuous questions, that are surprisingly hard to answer. In our compilation of the matter we have seen several proofs that were either incomprehensible or severely flawed and probably both. All the more reason to present the theory in a comprehensible way with correct proofs. The key to achieving this lies in studying Hilbert and Jacobson rings simultaneously, in the end it turns out, that they really are the same thing.

(2.164) Definition: (viz. 1294)

(i) Let $(R,+,\cdot)$ be an integral domain and denote its quotient field by $E := \mathrm{QUOT}(R)$. Then R is said to be a **Goldman domain**, iff it satisfies one of the following three equivalent properties:

 (a) There is some $0 \neq u \in R$ such that the localisation R_u is a field.

 (b) There is some $0 \neq u \in R$ such that the quotient field of R is $E = R[1/u]$.

 (c) The quotient field E of R is finitely generated, as an R-algebra.

(ii) Let $(R,+,\cdot)$ be a commutative ring, then a prime ideal $\mathfrak{g} \trianglelefteq_{\mathrm{i}} R$ is said to be a **Goldmann ideal**, iff the quotient ring $R/\mathfrak{g}$ is a Goldman domain.

(iii) Let $(R,+,\cdot)$ be a commutative ring, then R is said to be a **Hilbert ring**, iff every Goldman ideal of R, already is a maximal ideal of R.

(2.165) Remark:

- By property (a) in a Goldman domain R, there is some $u \in R$ with $u \neq 0$, such that any element $x \in E$ of the quotient field is of the form $x = a/u^n$ for some $a \in R$ and some $n \in \mathbb{N}$. The element u can be taken to be the same for all elements $x \in E$.

- If $\mathfrak{g} \trianglelefteq_{\mathrm{i}} R$ is a Goldman ideal, then $R/\mathfrak{g}$ is an integral domain, as $\mathfrak{g}$ is prime. The second defining property means, that there is some $u \in R$ with $u \notin \mathfrak{g}$ such that the quotient field of $R/\mathfrak{g}$ is generated by the single element $1/(u+\mathfrak{g})$, formally

$$\mathrm{QUOT}\left(R\Big/\mathfrak{g}\right) \;=\; \left(R\Big/\mathfrak{g}\right)\left[\frac{1}{u+\mathfrak{g}}\right]$$

(2.166) Example:

- Any field $(F,+,\cdot)$ is a Goldman domain: Clearly localisation in 1 yields $F = F_1$ so F satisfies property (a) required for a Goldman domain. Also the ring of power series $F[\![t]\!]$ in one variable over a field is a Goldman domain. This is due to the fact that the quotient field of $F[\![t]\!]$ is the field of Laurent series $F[\![t]\!][t^{-1}]$, as we will see in (7.30.(v)). As this is the localisation of $F[\![t]\!]$ in t we have property (a) again.

- Likewise, if $p \in \mathbb{Z}$ is a prime number then the local ring $\mathbb{Z}_{(p)} := (\mathbb{Z} \setminus p\mathbb{Z})^{-1}\mathbb{Z}$ is a Goldman domain. This is due to the fact that we only need one more number to divide by, to build up the quotient field $\mathbb{Q} = \mathbb{Z}_{(p)}[1/p]$, so we have a Goldman domain by property (b) above.

- The ring of integers $\mathbb{Z}$ is a Hilbert ring, but not a Goldman domain. We will see this in greater generality in (2.169). A special case of this theorem is the following: If R is a PID, then R is a Hilbert ring if and only if R has infinitely many prime ideals. And R is a Goldman domain if and only if R has finitely many prime ideals only.

- The polynomial ring $R[t]$ will *never* be a Goldman domain. We will prove this in (2.167.(iii)) below, but the proof will already make use of (2.169), as well.

- If $(F, +, \cdot)$ is a field, then the polynomial ring $F[t]$ is a Jacobson ring and we will see in (2.171.(iv)) that this amounts to $F[t]$ being a Hilbert ring. And (2.170.(iv)) tells us that even $F[t_1, \ldots, t_n]$ is a Hilbert (equivalently a Jacobson) ring.

 Prob We will prove property (c) in the definition in (2.33) of Jacobson rings: If $\mathfrak{p} \trianglelefteq_{\mathrm{i}} F[t]$ is a prime ideal, we distinguish two cases: For $\mathfrak{p} = 0$ we get $\bigcap \{ \mathfrak{m} \in \operatorname{Smax}(F[t]) \mid \mathfrak{p} \subseteq \mathfrak{m} \} = \operatorname{JAC}(F[t])$ and by (2.7.(ii)) we know $\operatorname{JAC}(F[t]) = 0 = \mathfrak{p}$ by. And if $\mathfrak{p} \neq 0$, then $\mathfrak{p}$ already is maximal, as $F[t]$ is a PID and we have (2.79.(i)). Thus $\bigcap \{ \mathfrak{m} \in \operatorname{Smax}(F[t]) \mid \mathfrak{p} \subseteq \mathfrak{m} \} = \bigcap \{ \mathfrak{p} \} = \mathfrak{p}$.

(2.167) Proposition: (viz. 1295)

(i) Let $(R, +, \cdot)$ be a Goldman domain and denote its quotient field by $E := \operatorname{QUOT}(R)$. An itermediate ring S of $E : R$ (that is $S \subseteq E$ is an R-subalgebra of E) is a Goldman domain, as well.

(ii) If $(R, +, \cdot)$ is any commutative ring and $u \in R \setminus \operatorname{NIL}(R)$ is an element that is not a nilpotent of R, then there is a Goldman ideal $\mathfrak{g} \trianglelefteq_{\mathrm{i}} R$ such that $u \notin \mathfrak{g}$ and $(R/\mathfrak{g})_{u+\mathfrak{g}}$ is a field.

(iii) For any commutative ring $(R, +, \cdot)$, the polynomial ring $R[t]$ is *not* a Goldman domain. Consequentially, if $S : R$ is any ring extension in which R is an integral domain and $x \in S$ is any element, such that $R[x]$ is a Goldman domain, then $R[x] : R$ is algebraic.

(iv) If $(R, +, \cdot)$ is an integral domain with quotient field $E := \operatorname{QUOT}(R)$ and $u \in R$ is a non-zero element of R, then the following statements are equivalent

 (a) $E = R[1/u]$

 (b) R_u is a field

 (c) $u \in \bigcap \{ \mathfrak{p} \in \operatorname{Spec}(R) \mid \mathfrak{p} \neq 0 \}$

 (d) $u \in \bigcap \{ \sqrt{\mathfrak{a}} \mid \mathfrak{a} \trianglelefteq_{\mathrm{i}} R, \mathfrak{a} \neq 0 \}$

(v) If $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is an ideal of some commutative ring $(R, +, \cdot)$, then the radical of $\mathfrak{a}$ is the intersection of all Goldman ideals of R, that contain $\mathfrak{a}$, formally that is

$$\sqrt{\mathfrak{a}} = \bigcap \{ \mathfrak{g} \trianglelefteq_{\mathrm{i}} R \text{ Goldman ideal} \mid \mathfrak{a} \subseteq \mathfrak{g} \}$$

(vi) Let $(S,+,\cdot)$ be an integral domain and $R \subseteq S$ be a sub-ring, such that $S : R$ is algebraic. Then we get the implication (a) $\Longrightarrow$ (b) for the statements below. And if $S : R$ also is finitely generated, then we find the equivalence of

(a) R is a Goldman domain

(b) S is a Goldman domain

(2.168) Proposition: (viz. 816)

(i) Let $(R,+,\cdot)$ be a commutative ring and $\mathfrak{n} \trianglelefteq_{\mathrm{i}} R[t]$ be a maximal ideal of the polynomial ring. Suppose $\mathfrak{m} := \mathfrak{n} \cap R = \{\, a \in R \mid a\mathbf{1} \in \mathfrak{n} \,\}$ is a maximal ideal, too. Then there is a monic polynomial $f \in R[t]$ such that

(1) $\mathfrak{n} = \mathfrak{m}[t] + fR[t]$

(2) $f + \mathfrak{m}[t] \in R[t]/\mathfrak{m}[t]$ is a prime element

(ii) Let $(R,+,\cdot)$ be an integral domain and $E := \mathrm{QUOT}(R)$ be its quotient field. We denote the natural inclusion by $\iota : R[t] \hookrightarrow E[t]$, which is given to be $\iota(f) := \sum_k (f[k]/1)\, t^k$. Then we obtain a one-to-one correspondence between the prime ideals of $E[t]$ and the prime ideals $\mathfrak{p}$ of $R[t]$ that satisfy $\mathfrak{p} \cap R = 0$. And this correspondence is given to be

$$\begin{array}{rcl} \mathrm{Spec}\big(E[t]\big) & \longleftrightarrow & \big\{\, \mathfrak{p} \in \mathrm{Spec}\big(R[t]\big) \mid \mathfrak{p} \cap R = 0 \,\big\} \\ \mathfrak{u} & \mapsto & \{\, f \in R[t] \mid \iota(f) \in \mathfrak{u} \,\} \\ \left\{ \displaystyle\sum_{k=0}^{\infty} \frac{f[k]}{u} t^k \;\middle|\; f \in \mathfrak{p},\, u \neq 0 \right\} & \hookleftarrow & \mathfrak{p} \end{array}$$

(2.169) Theorem: (viz. 1297)
Let $(R,+,\cdot)$ be a noetherian integral domain. Then R is a Goldman domain if and only if R has only finitely many prime ideals. That is we have the equivalence

$$R \text{ Goldman domain} \iff \#\mathrm{Spec}(R) < \infty$$

Thereby the direction " $\Longleftarrow$ " is true for general integral domains R. And if R is a noetherian Goldman domain R, then R already is a field or a 1-dimensional domain, since we get

$$\mathrm{kdim}(R) \;\leq\; 1$$

Now suppose R is a noetherian integral domain of $\mathrm{kdim}(R) = 1$, that is $\mathrm{Spec}(R) = \mathrm{Smax}(R) \cup \{0\}$ where 0 is not a maximal ideal of R. Then the following four statements are equivalent

(a) $\mathrm{JAC}(R) = 0$

(b) $\mathrm{Spec}(R)$ is an infinite set

(c) R is a Hilbert ring

(d) R is *not* a Goldman domain

(2.170) Lemma: (viz. 1298)

(i) Let $(R,+,\cdot)$ be a Hilbert ring and consider any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$. Then the quotient ring $R/\mathfrak{a}$ is a Hilbert ring, again.

(ii) Let $(R,+,\cdot)$ and $(S,+,\cdot)$ be commutative rings, such that S is a Hilbert ring. If $\varphi : S \twoheadrightarrow R$ is an epimorphism of rings, then R is a Hilbert ring, as well.

(iii) Let $(R,+,\cdot)$ be a Hilbert ring and A be a finitely generated R-algebra. Then (1) A is a Hilbert ring, as well and (2) if $\mathfrak{n} \in \operatorname{Smax}(A)$ is a maximal ideal, then $\mathfrak{m} := \mathfrak{n} \cap R \trianglelefteq_{\mathrm{i}} R$ is a maximal ideal of R, again. Finally, in this case, (3) $A/\mathfrak{n}$ is a finite field extension of $R/\mathfrak{m}$ [under the scalar multiplication $(a+\mathfrak{m})(f+\mathfrak{n}) := af+\mathfrak{n}$ where $a \in R$ and $f \in A$]

$$\left[A \Big/ \mathfrak{n} : R \Big/ \mathfrak{m} \right] \; < \; \infty$$

(iv) A special case of (iii) is the following: If $(R,+,\cdot)$ is a Hilbert ring, then $R[t_1,\ldots,t_n]$ is a Hilbert ring again. And if $\mathfrak{n}$ is a maximal ideal of $R[t_1,\ldots,t_n]$, then $\mathfrak{n} \cap R$ is a maximal ideal of R.

(2.171) Corollary: (viz. 1300)

(i) Let $(R,+,\cdot)$ be an integral domain, as we consider $R \subseteq R[t]$ to be a subset of the polynomial ring, we get $\mathfrak{u} \cap R = \{\, a \in R \mid a\mathbf{1} \in \mathfrak{u} \,\} \trianglelefteq_{\mathrm{i}} R$ for any ideal $\mathfrak{u} \trianglelefteq_{\mathrm{i}} R[t]$. And thereby the following four statements are equivalent

 (a) R is a Goldman domain

 (b) $0 \trianglelefteq_{\mathrm{i}} R$ is a Goldman ideal

 (c) $\bigcap \{\, \mathfrak{p} \in \operatorname{Spec}(R) \mid \mathfrak{p} \neq 0 \,\} \neq 0$

 (d) there is some maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R[t]$ such that $\mathfrak{m} \cap R = 0$

(ii) Let $(F,+,\cdot)$ be any commutative ring, then the following three properties are equivalent

 (a) F is a field

 (b) F is a Goldman domain satisfying $\textsc{jac}(F) = 0$

 (b) F is a Goldman domain and Hilbert ring

(iii) Let $(R,+,\cdot)$ be a commutative ring and $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ be a prime ideal of R. Then $\mathfrak{p}$ has been defined to be a Goldman ideal, iff (a). And this property (a) is equivalent to two other properties (b), (c) that are given to be

 (a) $R/\mathfrak{p}$ is a Goldman domain

 (b) there is some $u \in \bigcap \{\, \mathfrak{q} \in \operatorname{Spec}(R) \mid \mathfrak{p} \subset \mathfrak{q} \,\} \setminus \mathfrak{p}$

 (c) there is some maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} R[t]$ such that $\mathfrak{p} = \mathfrak{m} \cap R$

(iv) Let $(R,+,\cdot)$ be any commutative ring, then the following four properties are equivalent

(a) R is a Hilbert ring

(b) R is a Jacobson ring

(c) If $\mathfrak{m} \in \mathrm{Smax}(R[t])$ then $\mathfrak{m} \cap R \trianglelefteq_{\mathrm{i}} R$ is a maximal ideal again

(d) *Zariski's Lemma:* If A is a finitely generated R algebra, such that A is a field, then A already is finitely generated, as an R-module.

NOTA We have found 3 equivalent properties for Goldman domains in (2.164.(i)) and another 3 in (i) above. A Jacobson ring has been defined in (2.33) by 6 equivalent properties. Altogether the above list (iv) thereby boasts 14 different equivalences!

(2.172) Lemma: (viz. 1303)
Let $(R,+,\cdot)$ be a Jacobson ring, as defined in (2.33) - note that by (2.171.(iv)) this is equivalent to R being a Hilbert ring. Then the Jacobson property has the following hereditary properties:

(i) For any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ the quotient ring $R/\mathfrak{a}$ is jacobson.

(ii) If $\varphi : R \twoheadrightarrow S$ is an epimorphism of rings onto another ring $(S,+,\cdot)$, then the image S is jacobson.

(iii) If $S : R$ is an integral ring extension, where R and S are arbitrary commutative rings, then R is jacobson, if and only if S is jacobson.

(iv) For any $u \in R$ the localisation R_u is a Jacobson ring again and the one-to-one correspondence of prime ideals of R_u extends to maximal ideals, that is we get

$$\begin{array}{rcl} \mathrm{Smax}\big(R_u\big) & \longleftrightarrow & \{\, \mathfrak{m} \in \mathrm{Smax}(R) \mid u \notin \mathfrak{m} \,\} \\ \mathfrak{n} & \mapsto & \mathfrak{n} \cap R \\ \mathfrak{m}\, R_u & \hookleftarrow & \mathfrak{m} \end{array}$$

NOTA If $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ is a prime ideal, then the localisation $R_{\mathfrak{p}}$ need *not* be jacobson. If it was, we had $\mathrm{NIL}(R_{\mathfrak{p}}) = \mathrm{JAC}(R_{\mathfrak{p}}) = \mathfrak{p}R_{\mathfrak{p}}$ as $R_{\mathfrak{p}}$ is a local ring. But this implies $\mathfrak{p} = 0$ already.

Chapter 3

Modules

3.1 Defining Modules

The notion of a module is *the* cornerstone of algebra - it is sufficiently general to cover countless different situations, of all fields of mathematics and specific enough, as to produce a vast amount of properties to exploit. Because of its importance we have chosen to give a very precise definition of what a module is exactly: For the time being we use the binary operation $\diamond$ to denote the scalar multiplication in order to be able to write down the properties of a module in great detail. However we will soon follow the customary simplification to just write ax instead of $a \diamond x$, as the properties of a module will guarantee that this can be done safely.

(3.1) Definition:
Let $(R, +, \cdot)$ be a ring, then the triple $(M, +, \diamond)$ is said to be an R**-module**, iff $M \neq \emptyset$ is a non-empty set and $+$ resp. $\diamond$ are binary operations of the form $+ : M \times M \to M : (x, y) \mapsto x + y$ and $\diamond : R \times M \to M : (a, x) \mapsto a \diamond x = ax$, that satisfy the following properties

(G) $(M, +)$ is a commutative group, that is the addition $+$ is *associative* and *commutative*, admits a neutral element (called the *zero-element*, which will be denoted by 0) and every element of M has an additive inverse. Formally

$$\begin{aligned} \forall\, x, y, z \in M &: x + (y + z) = (x + y) + z \\ \forall\, x, y \in M &: x + y = y + x \\ \exists\, 0 \in M\, \forall\, x \in M &: x + 0 = x \\ \forall\, x \in M\, \exists\, \overline{x} \in M &: x + \overline{x} = 0 \end{aligned}$$

(M) The *addition* $+$ and *scalar multiplication* $\diamond$ on M satisfy the following compatibility conditions regarding the operations of R

$$\begin{aligned} \forall\, a \in R\, \forall\, x, y \in M &: a \diamond (x + y) = (a \diamond x) + (a \diamond y) \\ \forall\, a, b \in R\, \forall\, x \in M &: (a + b) \diamond x = (a \diamond x) + (b \diamond x) \\ \forall\, a, b \in R\, \forall\, x \in M &: (a \cdot b) \diamond x = a \diamond (b \diamond x) \\ \forall\, x \in M &: 1 \diamond x = x \end{aligned}$$

(3.2) Remark:

- The notations in the definition above deserve some special attention. First note that - as always with binary operations - we wrote $x+y$ instead of $+(x,y)$. Likewise $a \diamond x$ instead of $\diamond(a,x)$ and of course $a+b$ instead of $+(a,b)$, $a \cdot b$ instead of $\cdot(a,b)$ (as we already did with rings).

- Recall that for a ring $(R,+,\cdot)$ the operation $+$ has been called *addition* and $\cdot$ has been called *multiplication* of R. In analogy, if $(M,+,\diamond)$ is an R-module, then $+$ is said to be the *addition* of M and $\diamond$ is called the *scalar multiplication* of M.

- Next note that we have used two different binary operations $+$, namely $+ : R \times R \to R$ of $(R,+,\cdot)$ and $+ : M \times M \to M$ of $(M,+,\diamond)$. At first it may be misleading to denote two different functions by the same symbol, but you will soon become used to it and appreciate the simplicity of this notation. It will not lead to ambiguities, as the neighbouring elements (a and b for $a+b$ in R, resp. x and y for $x+y$ in M) determine which of the two functions is to be applied. As an exercise it might be useful to rewrite the defining properties (M) using $+_R$ for $+$ in R and $+_M$ for $+$ in M. As an example let us reformulate the first two properties in this way

$$\begin{aligned} \forall\, a \in R\ \forall\, x,y \in M \quad a \diamond (x +_M y) &= (a \diamond x) +_M (a \diamond y) \\ \forall\, a,b \in R\ \forall\, x \in M \quad (a +_R b) \diamond x &= (a \diamond x) +_M (b \diamond x) \end{aligned}$$

- Note that the properties (G) of R-modules truly express that $(M,+)$ is a commutative group. In particular we employ the usual notational conventions for groups. E.g. we may omit the bracketing in sums due to the associativity of the addition $+$ of M

$$x+y+z := (x+y)+z$$

$$\sum_{i=1}^{n} x_i := \Big((x_1+x_2)+\ldots\Big)+x_n$$

 And as always the *neutral element* $0 \in M$ is uniquely determined again (if 0 and $0'$ are neutral elements, then $0' = 0+0' = 0'+0 = 0$). Likewise given $x \in M$ there is a uniquely determined $\overline{x} \in M$ such that $x+\overline{x} = 0$ and this is said to be the *negative* element of x, denoted by $-x := \overline{x}$ (if p and q are negative elements of x then $p = p+0 = p+(x+q) = q+(x+p) = q+0 = q$).

- Let $(R,+,\cdot)$ be any ring (with unit element 1) and M be an R-module, then we note some immediate consequences of the axioms above. Let $x \in M$ and recall that $-x$ denotes the negative of x, then

$$\begin{aligned} 0 \diamond x &= 0 \\ (-1) \diamond x &= -x \end{aligned}$$

 Prob as $0 = 0+0$ in R we get $0 \diamond x = (0+0) \diamond x = (0 \diamond x) + (0 \diamond x)$ from (M). And substracting $0 \diamond x$ once from this equality we find $0 = 0 \diamond x$. This may now be used to see $0 = 0 \diamond x = (1+(-1)) \diamond x = (1 \diamond x) + ((-1) \diamond x)$. Substracting $x = 1 \diamond x$ we find $-x = (-1) \diamond x$.

- We have already simplified the notations for modules rigorously. However it is still useful to introduce some further conventions. Recall that for rings $(R,+,\cdot)$ we wrote ab instead of $a\cdot b$. And we wrote $a-b$ instead of $a+(-b)$ and $ab+c$ instead of $(a\cdot b)+c$. The same is true for the addition in the module M: We will write $x-y$ instead of $x+(-y)$. Likewise we write ax instead of $a\diamond x$ and declare that the scalar multiplication $\diamond$ is of higher priority that the addition $+$. E.g.

 $$ax+y \;:=\; (a\diamond x)+y$$

 Note that it is unambiguously to write abx instead of the original terms $(a\cdot b)\diamond x = a\diamond(b\diamond x)$, as this equality has been one of the axioms for R-modules. Thus we may also omit the brackets in mixed terms with multiplication and scalar multiplication. These conventions contribute to the readability of the expressions, as you can surely see already.

- In contrast to rings (where we faithfully wrote $(R,+,\cdot)$ on every first occurrance of the ring) we will omit the operations $+$ and $\diamond$ when referring to the R-module $(M,+,\diamond)$. That is we will say "let M be an R-module" and think of $(M,+,\diamond)$ instead of M.

- What we defined here is also called a **left R-module**, this is to say that in the scalar multiplication $\diamond : R\times M\to M$ the ring R acts from the left. One might be tempted to regard right R-modules as well, i.e. structures $(M,+,\curvearrowleft)$ in which the ring R acts from the right $\curvearrowleft : M\times R\to M : (x,a)\mapsto x\curvearrowleft a$ that satisfy the analogous properites $(x+y)\curvearrowleft a = (x\curvearrowleft a)+(y\curvearrowleft a)$, $x\curvearrowleft(a+b) = (x\curvearrowleft a)+(x\curvearrowleft b)$, $x\curvearrowleft(a\cdot b) = (x\curvearrowleft a)\curvearrowleft b$ and $x\curvearrowleft 1 = x$. However this would only yield an entirely analogous theory: Recall the construction of the *opposite ring* $(R,+,\cdot)^{\mathrm{op}}$ in section 1.4. If $(M,+,\diamond)$ is a (left) R-module, then we obtain a right R^{op}-module $(M,+,\diamond)^{\mathrm{op}}$ by taking M as a set and $+$ as an addition again, but using a scalar multiplication that reverses the order of elements. That is we obtain a right R^{op}-module by

 $$(M,+,\diamond)^{\mathrm{op}} \;:=\; (M,+,\curvearrowleft) \text{ where } x\curvearrowleft a := a\diamond x$$

- The theory of R-modules is particularly simple in the case that the base ring R is a field. As this case historically has been studied first there is some special nomenclature: Suppose that V is an F-module, where $(F,+,\cdot)$ is a field. Then we will use the following notions

set theory	linear algebra
$(F,+,\cdot)$	base field
$(V,+,\diamond)$	vector space
elements of F	scalars
elements of V	vectors

(3.3) Example:

- Consider any commutative group $(G,+)$, then G becomes a $\mathbb{Z}$-module under the following scalar multiplication $\diamond : \mathbb{Z} \times G \to G$ [take a look at (1.29) for a proof]

$$k \diamond x \;:=\; \begin{cases} \sum_{i=1}^{k} x \text{ for } k > 0 \\ 0 \text{ for } k = 0 \\ \sum_{i=1}^{-k} (-x) \text{ for } k < 0 \end{cases}$$

- Let $(R,+,\cdot)$ be any ring and $\mathfrak{a} \;\leq_{\mathfrak{m}}\; R$ be a left-ideal of R (note that in particular $\mathfrak{a} = R$ is allowed). Then $\mathfrak{a}$ is an R module under the operations inherited from R, that is

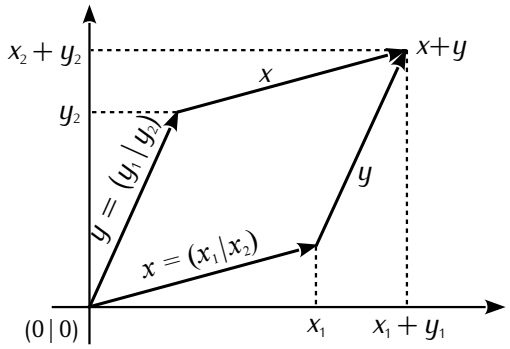
$$\begin{aligned} + \;:\; \mathfrak{a} \times \mathfrak{a} \to \mathfrak{a} \;&:\; (x,y) \mapsto x+y \\ \diamond \;:\; R \times \mathfrak{a} \to \mathfrak{a} \;&:\; (a,x) \mapsto ax \end{aligned}$$

 That is: Although we started with quite a lot of axioms for R-modules, examples are abundant - the theory of modules encompasses the theory of rings! And the proofs are full of examples how module theory can be put to good use in ring theory (e.g. the lemma of Nakayama).

- Consider any (not necessarily commutative) ring $(S,+,\cdot)$ and suppose $R \;\leq_{\mathrm{r}}\; S$ is a sub-ring of S. If now M is an S-module, then M becomes an R-module under the operations inherited from S

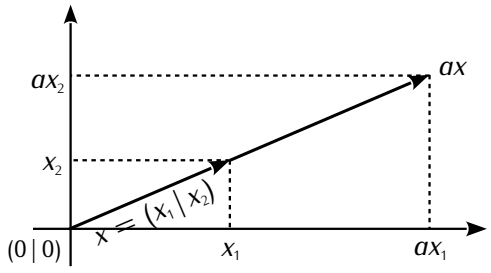
$$\begin{aligned} + \;:\; M \times M \to M \;&:\; (x,y) \mapsto x+y \\ \diamond \;:\; R \times M \to M \;&:\; (a,x) \mapsto ax \end{aligned}$$

- Let $(R,+,\cdot)$ and $(S,+,\cdot)$ be any two (not necessarily commutative) rings and consider a ring-homomorphism $\varphi : R \to S$. If now M is an S-module, then M also becomes an R-module under



$$\begin{aligned} + \;:\; M \times M \to M \;&:\; (x,y) \mapsto x+y \\ \diamond \;:\; R \times M \to M \;&:\; (a,x) \mapsto \varphi(a)x \end{aligned}$$

- Consider an arbitrary (not necessarily commutative) ring $(R,+,\cdot)$. Then R^n becomes an R-module (for any $1 \leq n \in \mathbb{N}$) under the point-wise operations $+ : R^n \times R^n \to R^n$ and $\diamond : R \times R^n \to R^n$



$$\begin{aligned} (x_1,\ldots,x_n) + (y_1,\ldots,y_n) \;&:=\; (x_1+y_1,\ldots,x_n+y_n) \\ a \diamond (x_1,\ldots,x_n) \;&:=\; (a \cdot x_1,\ldots,a \cdot x_n) \end{aligned}$$

 Note that the operations $+$ and $\cdot$ on the right hand side are those of the ring R, whereas the operations $+$ and $\diamond$ are thereby defined for the module R^n. Further note that in the case $n = 1$ we get $R^n = R$ and the addition $+$ on R^1 by definition coincides with the addition $+$ on R. This is precisely the reason why we did not need to distinguish between $+_R$ and $+_M$ - in case of doubt it doesn't matter, it's just the same.

(3.4) Remark:
The example R^n is the most basic and most important case of a module: It is the prototype of any free, finitely generated module, which is the best class of modules around. But it also is the first module that has been studied: In the case of the reals $R = \mathbb{R}$ the vector-spaces $\mathbb{R}^2$ and $\mathbb{R}^3$ are the domains of plane resp. of spatial geometry. And the addition of vectors in $\mathbb{R}^3$ is the way to describe the addition of velocities or forces in physics. It is here that we gain an intuition of what the addition and scalar multiplication of vectors is about:
First of a an n-tuple $x = (x_1, \ldots, x_n) \in R^n$ designates a point in space. But likewise we can think of x as an arrow pointing from the origin $0 \in R^n$ to x. From a mathematical point of view there is *no* distinction between points and arrows, as both are n-tuples. And there is good reason not to introduce any artificial distinction:
So this is what the addition $x + y$ of two n-tuples x, $y \in R^n$ does: It starts at point x and attaches the arrow y to it. Then the shifted arrow y ends at the point $x + y$. But you can also look at it in the following way: Start with the arrow x and attach arrow y (so that y starts, where x ends). Then the arrow $x + y$ points from 0 straight to the end of the shifted arrow y. That is $x + y$ is the diagonal in the parallelogram with the sides x and y:

It is a remarkable fact that nature can be described in these simple terms, but for marvellous reasons the addition of forces (amongst many other things) is precisely the point-wise addition of tuples in $\mathbb{R}^3$.
The scalar multiplication of R^n is understood best, if we think of an n-tuple x to be an arrow from 0 to x again. Then ax is just the arrow x stretched by the factor $a \in R$. (In case of $a < 1$ this is a reduction of length and in case $a < 0$ the arrow ax also points in the opposite direction).

(3.5) Definition:
Let $(R,+,\cdot)$ be a ring, then the quadrupel $(A,+,\cdot,\diamond)$ is said to be an R**-semi-algebra**, iff $A \neq \emptyset$ is a non-empty set and $+$, $\cdot$ resp. $\diamond$ are binary opertations of the form $+ : A \times A \to A$, $\cdot : A \times A \to A$ and $\diamond : R \times A \to A$ that satisfy the following properties

(R) $(A,+,\cdot)$ is a semi-ring, that is the addition $+$ is *associative* and *commutative*, admits a neutral element (called *zero-element*, denoted by 0), every element of A has an additive inverse, the multiplication $\cdot$ is *associative* and satisfies the *distributivity laws*. Formally

$$\begin{aligned}
\forall f,g,h \in A &: f+(g+h) = (f+g)+h \\
\forall f,g \in A &: f+g = g+f \\
\exists 0 \in A\, \forall f \in A &: f+0 = f \\
\forall f \in A\, \exists \overline{f} \in A &: f+\overline{f} = 0 \\
\forall f,g,h \in A &: f\cdot(g\cdot h) = (f\cdot g)\cdot h \\
\forall f,g,h \in A &: f\cdot(g+h) = (f\cdot g)+(f\cdot h) \\
\forall f,g,h \in A &: (f+g)\cdot h = (f\cdot h)+(g\cdot h)
\end{aligned}$$

(M) $(A,+,\diamond)$ is an R-module, that is the *addition* $+$ and *scalar multiplication* $\diamond$ of A satisfy the following compatibility conditions

$$\begin{aligned}
\forall a \in R\, \forall f,g \in A &: a\diamond(f+g) = (a\diamond f)+(a\diamond g) \\
\forall a,b \in R\, \forall f \in A &: (a+b)\diamond f = (a\diamond f)+(b\diamond f) \\
\forall a,b \in R\, \forall f \in A &: (a\cdot b)\diamond f = a\diamond(b\diamond f) \\
\forall f \in A &: 1\diamond f = f
\end{aligned}$$

(A) The *multiplication* $\cdot$ and *scalar multiplication* $\diamond$ of A are compatible in the following sense (note that this is some kind of associativity)

$$\forall a \in R\, \forall f,g \in A : (a\diamond f)\cdot g = a\diamond(f\cdot g) = f\cdot(a\diamond g)$$

If now $(A,+,\cdot,\diamond)$ is an R-algebra, then we transfer most of the notions of ring theory to the case of algebras, by refering to the semi-ring $(A,+,\cdot)$. To be precise introduce the following notions

$(A,+,\cdot,\diamond)$ is called		$(A,+,\cdot)$ is a(n)
R-algebra	$:\Longleftrightarrow$	ring
commutative	$:\Longleftrightarrow$	commutative
integral	$:\Longleftrightarrow$	integral domain
division algebra	$:\Longleftrightarrow$	skew-field
noetherian	$:\Longleftrightarrow$	commutative, noetherian ring
artinian	$:\Longleftrightarrow$	commutative, artinian ring
local	$:\Longleftrightarrow$	commutative, local ring
semi-local	$:\Longleftrightarrow$	commutative, semi-local ring

(3.6) Remark:

- By definition any R-semi-algebra $(A, +, \cdot, \diamond)$ has a (uniquely determined) neutral element of addition, denoted by 0 (that is $f + 0 = f$ for any $f \in A$). To be an R-algebra by definition means that the multiplication also admits a neutral element. That is there is some $1 \in A$ such that for any $f \in A$ we get $f \cdot 1 = f = 1 \cdot f$. And due to the associativity of $\cdot$ this *unit element* 1 is uniquely determined again.

- If $(A, +, \cdot, \diamond)$ is an R-algebra, then by definition $(A, +, \cdot)$ is a semi-ring and $(A, +, \diamond)$ is an R-module. In particular A inherits all the properties of these objects and we also pick up all notational conventions introduced for these objects. That is we write 0 for the zero-element and 1 for the unit element (supposed A is an R-algebra). Likewise we write $-f$ for the additive inverse of f (that is $f + (-f) = 0$ and f^{-1} for the multiplicative inverse of f (that is $f \cdot f^{-1} = 1 = f^{-1} \cdot f$), supposed such an element exists. In case you are not familiar with these conventions we recommend having a look at section 1.3.

- If A is a *commutative* R-semi-algebra, then condition (A) boils down to $(a \diamond f) \cdot g = a \diamond (f \cdot g)$ for any $a \in R$ and $f, g \in A$. Because if this property is satisfied then we already get $(a \diamond f) \cdot g = f \cdot (a \diamond g)$ from the commutativity $f \cdot (a \diamond g) = (a \diamond g) \cdot f = a \diamond (g \cdot f) = a \diamond (f \cdot g) = (a \diamond f) \cdot g$.

- If A is an R-algebra, i.e. an R-semi-algebra containing a unit element 1, then due to property (A) the scalar multiplication $\diamond$ can be expressed in terms of the ordinary multiplication of A with elements of the form $a \diamond 1$. To be precise, let $a \in R$ and $f \in A$, then we clearly obtain

$$(a \diamond 1) \cdot f \quad = \quad a \diamond f$$

- If $(R, +, \cdot)$ is an arbitrary (i.e. not necessarily commutative) ring and A is an R algebra with unit element 1_A then the elements $a1_A = a \diamond 1_A$ commute with any element $f \in A$. That is

$$\{\, a1_A \mid a \in R \,\} \quad \subseteq \quad \text{CEN}(A)$$

 This is due to property (A) of R-semi-algebras, as for any $a \in R$ and $f \in A$ we may compute $(a \diamond 1_A) \cdot f = a \diamond (1_A \cdot f) = a \diamond (f \cdot 1_A) = f \cdot (a \diamond 1_A)$.

- Note that property (A) in the definition of R-semi-algebras enables us to not only omit the multiplicative symbol $\cdot$ and scalar multiplication $\diamond$ but also the bracketing. Whenever we have a term of the form afg then we may use either bracketing $(af)g = a(fg)$ due to (A).

- Even if $a1_A = b1_A \in A$ we may *not* conclude $a = b \in R$. As a counterexample consider $A = \mathbb{Z}_4$ which is an algebra over $R = \mathbb{Z}$. Then we have $1_A = 1 + 4\mathbb{Z}$ and $21_A = 61_A$. Later on we will give a name to this property: In a *torsion-free* R-algebra we may conclude $a = b$ from $a1_A = b1_A$.

- Let $(R, +, \cdot)$ be a commutative ring and A be an R-semi-algebra, then we can embed A into an R-algebra A' canonically: As a set take $A' := R \times A$ and define the following operations on A'

$$\begin{aligned} (a, f) + (b, g) &:= (a + b, f + g) \\ (a, f) \cdot (b, g) &:= (ab, fg + ag + bf) \end{aligned}$$

$$a \diamond (b,g) \quad := \quad (ab, ag)$$

Then $(A', +, \cdot, \diamond)$ truly becomes an R-algebra (the verification of this is left to the interested reader) with zero element $(0,0)$ and unit element $(1,0)$. And of course we get a canonical embedding (i.e. an injective homomorphism of R-algebras), by virtue of

$$A \hookrightarrow A' \; : \; f \mapsto (0, f)$$

(3.7) Example:

- Let $(R, +, \cdot)$ be a commutative ring then, R becomes an R-module (even an R-algebra) canonically under its addition $+$ as an addition of vectors and its multiplication $\cdot$ as both, its multiplication and scalar-multiplication. I.e. if we let $A := R$, then R becomes an R-algebra $(A, +, \cdot, \diamond)$, under the operations

$$\begin{aligned} + \; : \; A \times A \to A \quad &: \quad (f,g) \mapsto f + g \\ \cdot \; : \; A \times A \to A \quad &: \quad (f,g) \mapsto fg \\ \diamond \; : \; R \times A \to A \quad &: \quad (a,f) \mapsto af \end{aligned}$$

 In the following - whenever we say that we regard some ring $(R, +, \cdot)$ as an R-module - we will refer to this construction. And in this case any subset $\mathfrak{a} \subseteq R$ is an ideal of R if and only if i t is an R-sub-module

$$\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R \quad \Longleftrightarrow \quad \mathfrak{a} \leq_{\mathfrak{m}} R$$

- Let $(R, +, \cdot)$ be a commutative ring again and $I \neq \emptyset$ be any non-empty set, then we take to be the set $A := \mathcal{F}(I, R)$ of functions from I to R. Note that this includes the case $A = R^n$ by taking $I := 1 \ldots n$. Then A becomes an R-algebra $(A, +, \cdot, \diamond)$, under the point-wise operations

$$\begin{aligned} + \; : \; A \times A \to A \quad &: \quad (f,g) \mapsto (i \mapsto f(i) + g(i)) \\ \cdot \; : \; A \times A \to A \quad &: \quad (f,g) \mapsto (i \mapsto f(i) \cdot g(i)) \\ \diamond \; : \; R \times A \to A \quad &: \quad (a,f) \mapsto (i \mapsto af(i)) \end{aligned}$$

- Likewise let $(R, +, \cdot)$ be a commutative ring and $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ be an ideal of R. Then we may consider the quotient ring $A := R/\mathfrak{a}$ as an R-algebra $(A, +, \cdot, \diamond)$, under the following operations

$$\begin{aligned} + \; : \; A \times A \to A \quad &: \quad (b + \mathfrak{a}, c + \mathfrak{a}) \mapsto (b + c) + \mathfrak{a} \\ \cdot \; : \; A \times A \to A \quad &: \quad (b + \mathfrak{a}, c + \mathfrak{a}) \mapsto (bc) + \mathfrak{a} \\ \diamond \; : \; R \times A \to A \quad &: \quad (a, b + \mathfrak{a}) \mapsto (ab) + \mathfrak{a} \end{aligned}$$

- This is a special case of the following general concept: Consider any two commutative rings $(R, +, \cdot)$ and $(A, +, \cdot)$ and regard an arbitrary ring-homomorphism $\varphi : R \to A$. Then A can be considered to be an R-algebra under its own addition $+$ and its own multiplication $\cdot$ as multiplication and the scalar multiplication is multiplication in A with the imported elements $\varphi(a)$. That is A becomes an R-algebra under the operations

$$
\begin{aligned}
+ \;:\; A \times A \to A \quad &:\quad (f,g) \mapsto f+g \\
\cdot \;:\; A \times A \to A \quad &:\quad (f,g) \mapsto fg \\
\diamond \;:\; R \times A \to A \quad &:\quad (a,f) \mapsto \varphi(a)f
\end{aligned}
$$

- Generally: If $(S,+,\cdot)$ is a semi-ring, then $(S,+)$ can not only turned into an $\mathbb{Z}$-module, but S even becomes a $\mathbb{Z}$-semi-algebra under its own addition and multiplication and $\mathbb{Z} \times S \to S : (a,x) := ax$ as a scalar multiplication. Recall that in (3.3) we have defined the scalar multiplication ax to be $ax := 0$ for $a = 0$, $ax := x + x + \cdots + x$ (a-times) for $a > 0$ and $ax := (-a)(-x)$ for $a < 0$. A proof of this statement is provided in the proof of (1.29).

- The most general case of the above is the following: Let $(R,+,\cdot)$ be any (that is even a non-commutative) ring. Then R still is an R-module under the above operations. But R no longer needs to be R-algebra. Likewise consider a second ring $(S,+,\cdot)$ and a ring-homomorphism $\varphi : R \to S$. Then S is an R-module under the above operations.

 $$
 \begin{aligned}
 + \;:\; S \times S \to S \quad &:\quad (x,y) \mapsto x+y \\
 \diamond \;:\; R \times S \to S \quad &:\quad (a,x) \mapsto \varphi(a)y
 \end{aligned}
 $$

 Again S, need not be an R-algebra, in general. However S becomes an R-algebra (under its own multiplication), if the image of R under φ is contained in the center of S, that is if

 $$\varphi(R) \quad \subseteq \quad \text{CEN}(S) \;:=\; \{\, x \in S \mid \forall\, y \in S : xy = yx \,\}$$

- An example of the above situation will be the ring of $n \times n$ matrices over a commutative ring $(R,+,\cdot)$. Recall the construction of matrices given in section 1.4 (for more details confer to section 4.1) and let $S := \text{mat}_n(R)$. Then we obtain a homomorphism of rings by letting

 $$\varphi \;:\; R \to S \;:\; a \mapsto \begin{pmatrix} a & & 0 \\ & \ddots & \\ 0 & & a \end{pmatrix}$$

 And as R is commutative it is clear, that $\varphi(R) \subseteq \text{CEN}(S)$ (in fact it even is true that $\varphi(R) = \text{CEN}(S)$) and hence S becomes a well-defined R-algebra (under the usual multiplication and addition of matrices). Of course this multiplication is just the same, as the point-wise multiplication by a.

(3.8) Definition:
Let $(R,+,\cdot)$ be a ring and M be an R-module. Then a subset $P \subseteq M$ is said to be an **R-sub-module** of M, iff it satisfies the following three properties

(1) $0 \in P$

(2) $x, y \in P \implies x + y \in P$

(3) $a \in R,\, x \in P \implies ax \in P$

And in this case we will write $P \leq_{\mathfrak{m}} M$. Likewise if A is a R-semi-algebra and $P \subseteq A$ is a subset, then P is said to be an R-**sub-semi-algebra**, iff it is both, a sub-module and sub-semi-ring of A Formally iff

(M) $P \leq_{\mathfrak{m}} A$

(4) $f, g \in P \implies fg \in P$

And in this case we will write $P \leq_{\mathfrak{b}} A$. In this case P is said to be an **unital** R-**sub-semi-algbra** iff P contains a unit element for itself, that is iff P satisfies the properties

(B) $P \leq_{\mathfrak{b}} A$

(U) $\exists\, e \in P$ such that $\forall\, f \in P$ we have $ef = f = fe$

If the unit element $e \in P$ is just the unit element $1 \in A$ (that is, in case P is both, a sub-module and sub-ring of A) then P is said to be an R-**subalgebra** of A, formally that is iff P satisfies

(B) $P \leq_{\mathfrak{b}} A$

(5) $1 \in P$

And in this case we will write $P \leq_{\mathfrak{a}} A$. Let now A be an R-semi-algebra again. Then a subset $\mathfrak{a} \subseteq A$ is said to be an R-**algebra-ideal** of A. iff it is both, an ideal and a sub-module of A, formally iff it satisfies

(M) $\mathfrak{a} \leq_{\mathfrak{m}} A$

(I) $f \in \mathfrak{a}, g \in A \implies fg \in \mathfrak{a}$ and $gf \in \mathfrak{a}$

And in this case we write $\mathfrak{a} \trianglelefteq_{\mathfrak{a}} A$. Having defined all these notions the set of all sub-modules of an R-module M is denoted by $\mathrm{Subm}(M)$. Likewise $\mathrm{Subb}(A)$ denotes the set of all R-sub-semi-algebras, $\mathrm{aIdeal}(A)$ denotes the set of all algebra-ideals of a semi-algebra A. And finally the set of all R-subalgebras of an R-algebra A id denoted by $\mathrm{Suba}(A)$. Formally we define

$$\begin{aligned}
\mathrm{Subm}(M) &:= \{\, P \subseteq M \mid P \leq_{\mathfrak{m}} M \,\} \\
\mathrm{Subb}(A) &:= \{\, P \subseteq A \mid P \leq_{\mathfrak{b}} A \,\} \\
\mathrm{Suba}(A) &:= \{\, P \subseteq A \mid P \leq_{\mathfrak{a}} A \,\} \\
\mathrm{aIdeal}(A) &:= \{\, \mathfrak{a} \subseteq A \mid P \leq_{\mathfrak{b}} A \,\}
\end{aligned}$$

(3.9) Remark:

- If $P \leq_{\mathfrak{m}} M$ is a sub-module (of the R-module M, where $(R, +, \cdot)$ is an arbitrary ring), then $P \leq_{\mathfrak{g}} M$ already is a *subgroup* of $(M, +)$, too. That is $0 \in P$ and for any $x, y \in P$ we get $-x \in P$ and $x + y \in P$. Thereby $-x \in P$ follows from (3) by regarding $a := -1$, as in this case we get $-x = (-1) \diamond x \in P$ already.

- Likewise if A is an R-algebra (over an arbitrary ring $(R, +, \cdot)$), then we only need to check properties (1), (2), (4) and (5), as (3) follows from (4): Given $f \in R$ and $a \in A$ we get $af = (a1_A) \diamond f \in P$.

- Let A be an R-semi-algebra over the ring $(R, +, \cdot)$, then any sub-semi-algebra of A already is a a sub-semi-ring of A, formally

$$P \leq_{\mathrm{b}} A \quad \Longrightarrow \quad P \leq_{\mathrm{s}} A$$

 Prob Properties (1), (2) and (4) of sub-semi-algebras and sub-semi-rings coincide. It only remains to check property (3) of sub-semi-rings: consider any $f \in P$, then $-f = (-1)f \in P$ by (3) of sub-semi-algebras.

- If $P \leq_{\mathrm{m}} M$ is a sub-module (of the R-module M, where $(R, +, \cdot)$ is a integral domain) then we obtain another sub-module of M by letting

$$\mathrm{Hull}(P) \;:=\; \{\, x \in M \mid \exists\, a \in R : a \neq 0 \text{ and } ax \in P \,\}$$

 Thereby $P \subseteq \mathrm{Hull}(P) \leq_{\mathrm{m}} M$ of course. Prob Clearly $p = 1 \cdot p \in \mathrm{Hull}(P)$ for any $p \in P$ such that $P \subseteq \mathrm{Hull}(P)$. In particular $0 \in \mathrm{Hull}(P)$ which is property (1). In (3) we are given $u \in R$ and $x \in \mathrm{Hull}(P)$. That is $ax \in P$ for some $a \neq 0$. Then $a(ux) = (au)x = (ua)x = u(ax) \in P$ such that $ux \in \mathrm{Hull}(P)$. Likewise, if $x, y \in \mathrm{Hull}(P)$ then ax and $by \in P$ for some $a, b \in R$ with $a, b \neq 0$. Now $ab(x + y) = (ab)x + (ab)y = b(ax) + a(by) \in P$. But as R is an integral domain we have $ab \neq 0$, as well and thereby $x + y \in \mathrm{Hull}(P)$, which is property (2).

- If A is an R-(semi-)algebra over some ring $(R, +, \cdot)$ then the center $\mathrm{cen}(A) \subseteq A$ (i.e. the elements of A that commute with all other elements) is an R-sub-(semi-)algebra of A again

$$\mathrm{cen}(A) \;=\; \{\, f \in A \mid \forall\, g \in A : fg = gf \,\} \quad \leq_{\mathrm{b}} A$$

 Prob Clearly $0 \in \mathrm{cen}(A)$ as for any $g \in A$ we have $0g = 0 = g0$ and if $a \in R$, $f, f' \in \mathrm{cen}(A)$ then we get $(af)g = a(fg) = f(ag) = (ag)f = a(gf) = g(af)$ and $(f + f')g = fg + f'g = gf + gf' = g(f + f')$ such that af and $f + f' \in \mathrm{cen}(A)$ again. Also $(ff')g = f(f'g) = f(gf') = (fg)f' = (gf)f' = g(ff')$ implies $ff' \in \mathrm{cen}(A)$. Altogether $\mathrm{cen}(A) \leq_{\mathrm{b}} A$ and if $1 \in A$ is the unit element then $1g = g = g1$ for any $g \in A$ such that $1 \in \mathrm{cen}(A)$ again.

- Let A be an R-semi-algebra over the ring $(R, +, \cdot)$, then $\mathfrak{a}$ is an algebra ideal of A iff it is an ideal and R-sub-semi-algebra of A, formally

$$\mathfrak{a} \trianglelefteq_{\mathrm{a}} A \quad \Longleftrightarrow \quad \mathfrak{a} \leq_{\mathrm{b}} A \text{ and } \mathfrak{a} \trianglelefteq_{\mathrm{i}} A$$

 Prob The implication $\Longleftarrow$ is clear: (M) of algebra-ideals is identical to (M) of sub-semi-algebras and (I) of algebra ideals just combines (4) and (5) of ideals. Conversely we first check property (4) of sub-semi-algebras: if $f, g \in \mathfrak{a}$, then in particular $g \in A$ and hence $fg \in \mathfrak{a}$ by (4) of algebra-ideals. Now properties (1) and (2) of ideals are contained in (M) of algebra ideals ((4) and (5) are (I) again). Thus it only remains to check property (3) of ideals. But if $f \in \mathfrak{a}$ then, as before $-f = (-1)f \in \mathfrak{a}$ by property (3) of algebra-ideals.

- If A even is an R-algebra over the ring $(R, +, \cdot)$, then there is no difference between ideals and algebra-ideals of A, formally

$$\mathfrak{a} \trianglelefteq_{\mathrm{a}} A \quad \Longleftrightarrow \quad \mathfrak{a} \trianglelefteq_{\mathrm{i}} A$$

Prob We have already seen $\mathfrak{a} \trianglelefteq_{\mathsf{a}} A \implies \mathfrak{a} \trianglelefteq_{\mathsf{i}} A$ above. Further we have already argued that it only remains to check property (3) of algebra-ideals: thus consider any $a \in R$ and $f \in \mathfrak{a}$, then $a1 \in A$ (where $1 \in A$, as A is an R-algebra) and hence $af = (a1)f \in \mathfrak{a}$ by (I).

(3.10) Proposition: (viz. 749)
Fix any ring $(R, +, \cdot)$ and for the moment being let $\star$ appreviate any one of the words *R-module*, *R-semi-algebra* or *R-algebra* and let M be a $\star$. Further consider an arbitrary family (where $i \in I \neq \emptyset$) $P_i \subseteq M$ of sub-$\star$s of M. Then the intersection of the P_i is a sub-$\star$ again

$$\bigcap_{i \in I} P_i \quad \subseteq \quad M \quad \text{is a sub-}\star$$

Likewise let A be an R-semi-algebra and let $\mathfrak{a}_i \trianglelefteq_{\mathsf{a}} A$ be an arbitrary (that is $i \in I \neq \emptyset$ again) family of R-algebra-ideals of A, then the intersection of the $\mathfrak{a}_i$ is an R-algebra-ideal of A again

$$\bigcap_{i \in I} \mathfrak{a}_i \quad \trianglelefteq_{\mathsf{a}} \quad A \quad \text{is an } R\text{-algebra-ideal}$$

(3.11) Definition:
Fix any ring $(R, +, \cdot)$ again, let $\star$ abbreviate any one of the words *R-module*, *R-semi-algebra* or *R-algebra* again and let M be a $\star$. If $X \subseteq M$ is an arbitrary subset then we define the **linear hull** $\mathrm{Lh}(X)$ resp. $\mathrm{Lh}_R(X)$ of X to be the following subset of M: If $X = \emptyset$, then we let $\mathrm{Lh}(\emptyset) := \{0\}$ and for $X \neq \emptyset$ we take to

$$\mathrm{Lh}(X) \quad = \quad \left\{ \sum_{i=1}^{n} a_i x_i \;\middle|\; 1 \leq n \in \mathbb{N},\, a_i \in R,\, x_i \in X \right\} \quad \subseteq \quad M$$

And the $\star$ **generated** by X is the intersection of all sub-$\star$s containing X:

$$\begin{aligned} \langle X \rangle_{\mathsf{m}} &:= \bigcap \{\, P \subseteq M \mid X \subseteq P \leq_{\mathsf{m}} M \,\} \\ \langle X \rangle_{\mathsf{b}} &:= \bigcap \{\, P \subseteq M \mid X \subseteq P \leq_{\mathsf{b}} M \,\} \\ \langle X \rangle_{\mathsf{a}} &:= \bigcap \{\, P \subseteq M \mid X \subseteq P \leq_{\mathsf{a}} M \,\} \end{aligned}$$

Nota in case there is any doubt concerning the module X is contained in, (e.g. $X \subseteq M \subseteq N$) we emphasize the R-module M used in this construction by writing $\langle X \subseteq M \rangle_{\mathsf{m}}$ or $\langle X \rangle_{\mathsf{m}} \leq_{\mathsf{m}} M$ and in literature there even is the notation $M\langle X \rangle_{\mathsf{m}}$, for the sub-module generated in M.

(3.12) Proposition: (viz. 749)
Fix any ring $(R, +, \cdot)$ and consider an R-module M containing the non-empty subset $X \subseteq M$, $X \neq \emptyset$. Then the sub-module generated by X is precisely the linear hull of X in M, formally

$$\langle X \rangle_{\mathsf{m}} \quad = \quad \left\{ \sum_{i=1}^{n} a_i x_i \;\middle|\; 1 \leq n \in \mathbb{N},\, a_i \in R,\, x_i \in X \right\}$$

And if A is an R-semi-algebra, $X \subseteq A$, $X \neq \emptyset$, then we can also describe the R-sub-semi-algebra generated by X explicitly. Namely we get the following description of this semi-algebra

$$\langle X \rangle_{\mathsf{b}} \;=\; \left\{ \sum_{i=1}^{n} a_i \prod_{j=1}^{m} x_{i,j} \;\middle|\; 1 \leq m,n \in \mathbb{N},\ a_i \in R,\ x_{i,j} \in X \right\}$$

Finally if A is an R-algebra, then the sub-algebra generated by X becomes $\langle X \rangle_{\mathsf{a}} = \langle X \cup \{1\} \rangle_{\mathsf{b}}$. And in the light of the explicit description above, we conclude that

$$\langle X \rangle_{\mathsf{a}} \;=\; \left\{ \sum_{i=1}^{n} a_i \prod_{j=1}^{m} x_{i,j} \;\middle|\; 1 \leq m,n \in \mathbb{N},\ a_i \in R,\ x_{i,j} \in X \cup \{1\} \right\}$$

(3.13) Remark:
In general the union $M \cup N$ of two modules need not be a module again, as it need not be closed under addition $+$. There is an important situation when this is the case, however: Let $(R,+,\cdot)$ be any ring, M be an R-module and for any $i \in I$ (where $I \neq \emptyset$) let $P_i \leq_{\mathsf{m}} M$ be sub-module of M. If the P_i form a *chain* - that is for any $i, j \in I$ we have $P_i \subseteq P_j$ or $P_j \subseteq P_i$ then the union

$$P \;:=\; \bigcup_{i \in I} P_i \quad \leq_{\mathsf{m}} \quad M$$

is a sub-module of M again. Likewise if A is an R-(semi)-algebra and for any $i \in I$ we have a sub-(semi)-algebra $P_i \leq_{\mathsf{b}} A$ of A, then their union *is* a sub-(semi)-algebra again

$$P \;:=\; \bigcup_{i \in I} P_i \quad \leq_{\mathsf{b}} \quad A$$

Prob As $I \neq \emptyset$ we have $0 \in P_i \subseteq P$ for any $i \in I$. Now consider $x, y \in P$ that is there are some $i, j \in I$ such that $x \in P_i$ and $y \in P_j$. As the P_i form a chain, we may assume $P_i \subseteq P_j$ without loss of generality. That is $x \in P_j$ as well and as P_j is a sub-module of M we hence get $ay \in P_j \subseteq P$ (for any $a \in R$) and $x + y \in P_j \subseteq P$ again. For the same reason, if the $P_i \leq_{\mathsf{b}} A$ are sub-(semi)-algebras of A, then the product $xy \in P_j \subseteq A$ is contained in P again.

3.2 First Concepts

In this and the following section we will introduce three separate concepts, that are all of fundamental importance. First we will introduce quotient modules - we have already studied quotient rings in (1.62), now we will generalize this concept to modules. Secondly we will turn our attention to torsion and annihilation. This is an important concept when it comes to analyzing the structure of a module, but will not occur in linear algebra. And finally we will introduce direct sums and products - the major tool for composing and decomposing modules over a common base ring.

(3.14) Definition: (viz. 750)
Let $(R,+,\cdot)$ be an arbitrary ring, consider an R-module M an R-sub-module $P \leq_{\mathsf{m}} M$ of M, then P induces an equivalence relation on M, by

$$x \sim y \quad :\Longleftrightarrow \quad y - x \in P$$

where x, $y \in M$. The equivalence classes under this relation are called **cosets** of P. For any $x \in M$ these are of the following form

$$x + P \;:=\; [x] \;=\; \{\, x + p \mid p \in P \,\}$$

Finally we denote the quotient set M modulo P to be the quotient set of M under this equivalence relation $\sim$. That is M/P is the set of all cosets, we denote it by

$$M \Big/ P \;:=\; M \Big/ \sim \;=\; \{\, x + P \mid x \in M \,\}$$

And thereby M/P can be turned into an R-module $(M/P,+,\diamond)$ again under the following operations

$$\begin{aligned} (x+P)+(y+P) &:= (x+y)+P \\ a \diamond (x+P) &:= (ax)+P \end{aligned}$$

Thereby $(M/P,+,\diamond)$ is also called the **quotient module** or **residue module** of M modulo P. Now consider an R-semi-algebra A and an R-algebra-ideal $\mathfrak{a} \trianglelefteq_{\mathsf{a}} A$. Then $A/\mathfrak{a}$ (in the sense above) not only is an R-module, but even becomes an R-semi-algebra $(A/\mathfrak{a},+,\cdot,\diamond)$, under the multiplication

$$(f+\mathfrak{a})(g+\mathfrak{a}) \;:=\; (fg)+\mathfrak{a}$$

Thereby $(A/\mathfrak{a},+,\cdot,\diamond)$ is also called the **quotient algebra** or **residue algebra** of A modulo $\mathfrak{a}$. And if A even is an R-algebra, then $(A/\mathfrak{a},+,\cdot,\diamond)$ is an R-algebra again, its unit element being given by $1+\mathfrak{a}$.

(3.15) Remark:
If $(R,+,\cdot)$ is any ring, then R is an R-module (even an R-algebra in case of a commutative ring) again (see above). And the property that $\mathfrak{a} \leq_{\mathsf{m}} R$ is a sub-module is precisely the same, as being a left-ideal. By the above definition $R/\mathfrak{a}$ thereby is an R-module again under the operations

$$(a+\mathfrak{a})+(b+\mathfrak{a}) \;=\; (a+b)+\mathfrak{a}$$

$$a \diamond (b + \mathfrak{a}) \quad = \quad (ab) + \mathfrak{a}$$

(3.16) Proposition: (viz. 750)
Correspondence Theorem: Let $(R, +, \cdot)$ be an arbitrary ring, M be an R-module and $L \leq_{\mathfrak{m}} M$ be any R-sub-module of M. Then we obtain the following correspondence of sub-modules

(i) Consider some R-sub-module $P \leq_{\mathfrak{m}} M$ such that $L \subseteq P$, then we obtain an R-sub-module P/L of the quotient module M/L by virtue of

$$P \Big/ L \quad := \quad \{ p + L \mid p \in P \} \quad \leq_{\mathfrak{m}} \quad M \Big/ L$$

and thereby for any element $x \in M$ we obtain the following equivalence for the *element of* relation

$$x + L \in P \Big/ L \quad \Longleftrightarrow \quad x \in P$$

(ii) Now the R-sub-modules of M/L correspond to the R-sub-modules of M containing L and this correspondence can be explicitly given to be

$$\begin{array}{rcl} \mathrm{Subm}\left(M \Big/ L\right) & \longleftrightarrow & \{ P \in \mathrm{Subm}(M) \mid L \subseteq P \} \\ U & \mapsto & \{ x \in M \mid x + L \in U \} \\ P \Big/ L & \hookleftarrow & P \end{array}$$

(iii) Consider an arbitrary family $P_i \leq_{\mathfrak{m}} M$ (where $i \in I$) of R-sub-modules of M such that for any $i \in I$ we get $L \subseteq P_i$. Then the intersection commutes with taking to quotients, that is we obtain

$$\bigcap_{i \in I} \left(P_i \Big/ L \right) \quad = \quad \left(\bigcap_{i \in I} P_i \right) \Big/ L$$

(iv) As in (iii) consider any $P_i \leq_{\mathfrak{m}} M$ where $i \in I$ and $L \subseteq P_i$, then the summation also commutes with taking to quotients, that is

$$\sum_{i \in I} \left(P_i \Big/ L \right) \quad = \quad \left(\sum_{i \in I} P_i \right) \Big/ L$$

(v) More generally consider any family of sumbodules $P_i \leq_{\mathfrak{m}} M$ (where $i \in I$) such that $L \subseteq \sum_i P_i$, then we obtain the following identity

$$\sum_{i \in I} \left(P_i + L \Big/ L \right) \quad = \quad \left(\sum_{i \in I} P_i \right) \Big/ L$$

(vi) Finally for any subset $X \subseteq M$ let us denote $X/L := \{ x + L \mid x \in X \}$ that is $X/L \subseteq M/L$, then we obtain the following identity

$$\langle X \Big/ L \rangle_{\mathfrak{m}} \quad = \quad \langle X \rangle_{\mathfrak{m}} + L \Big/ L$$

(3.17) Proposition: (viz. 752) **Modular Rule**
Let $(R,+,\cdot)$ be an arbitrary ring, M be an R module and P, Q and $U \leq_{\mathfrak{m}} M$ be R-sub-modules of M such that $P \subseteq Q$. Then we obtain

$$(Q \cap U) + P \;=\; Q \cap (P + U)$$

$$P \cap U = Q \cap U,\; P + U = Q + U \;\Longrightarrow\; P = Q$$

(3.18) Proposition: (viz. 865)
Let $(R,+,\cdot)$ be an arbitrary ring and N be an R-module. Further consider a cofinite sub-module $P \leq_{\mathfrak{m}} N$ of N, that is there are some $x_1,\ldots,x_n \in N$ such that we have the equality

$$P + \mathsf{Lh}\{\, x_1,\ldots,x_n \,\} \;=\; N$$

If further $P \neq N$, then there is a maximal sub-module M of N containing P. That is $M \leq_{\mathfrak{m}} N$ is a sub-module satisfying the following three properties

(1) $M \neq N$

(2) $P \subseteq M \subseteq N$

(3) $\forall\, Q \leq_{\mathfrak{m}} N$ we get $M \subseteq Q \subseteq N \implies M = Q$ or $M = N$

(3.19) Remark:
In (3.110) we will see, that $\mathbb{Q}$ (regarded as a $\mathbb{Z}$-module) does not have a single maximal sub-module. No wonder, that we also found $\mathbb{Q}$ to be ininitely generated: If it was finitely generated then by the proposition above there would be a maximal module containing $\{0\}$.

(3.20) Definition:
Let $(R,+,\cdot)$ be any ring and M be an R-module. Further consider an element $x \in M$ and an arbitrary subset $X \subseteq M$, then we introduce

(i) We define the **annihilator** of x to be the subset of elements of R, that multiply x to zero. Likewise the annihilator of X is the subset of elements of R that multiply all $x \in X$ to zero, simultaneously

$$\begin{aligned}
\mathsf{ann}(x) &:= \{\, a \in R \mid ax = 0 \,\} \\
\mathsf{ann}(X) &:= \{\, a \in R \mid \forall\, x \in X : ax = 0 \,\} \\
&= \bigcap_{x \in X} \mathsf{ann}(x)
\end{aligned}$$

If we want to emphasize the base ring in which the annihilator is generated, we also write $\mathsf{ann}_R(X)$ instead of $\mathsf{ann}(X)$. It is easy to see that any annihilator $\mathsf{ann}(X)$ is a left-ideal in R. Finally the set of all left-ideals of R occuring as annihilators of non-zero elements of M will be denoted by

$$\mathsf{Anns}(M) \;:=\; \{\, \mathsf{ann}(x) \mid x \in M,\; x \neq 0 \,\}$$

(ii) For $X \subseteq \{0\}$ we let $\mathrm{zd}_R(X) := \{0\}$ and if there is some $x \in X$ with $x \neq 0$ then we define the set of **zero-divisors** of X to be the subset of elements of R that multiply a non-zero $x \in X$ to zero

$$\mathrm{zd}_R(X) \;:=\; \{\, a \in R \mid \exists\, x \in X \;:\; x \neq 0 \text{ and } ax = 0 \,\} \;=\; \bigcup_{0 \neq x \in X} \mathrm{ann}(x)$$

(iii) The complement of the zero-divisors is called the set of **non-zero-divisors** of X, which we denote by $\mathrm{nzd}_R(X) := R \setminus \mathrm{zd}_R(X)$. And if there is some $x \in X$ with $x \neq 0$ then this set is given to be

$$\begin{aligned} \mathrm{nzd}_R(X) \;&:=\; R \setminus \mathrm{zd}_R(X) \\ &=\; \{\, a \in R \mid \forall\, x \in X \;:\; x \neq 0 \implies ax \neq 0 \,\} \\ &=\; \{\, a \in R \mid \forall\, x \in X \;:\; ax = 0 \implies x = 0 \,\} \end{aligned}$$

(iv) We thereby define the **torsion sub-module** of M to be the collection of elements of M that have an non-trivial annihilator (i.e. $ax = 0$ for some $a \neq 0$), formally that is

$$\begin{aligned} \mathrm{tor}(M) \;&:=\; \{\, x \in M \mid \exists\, a \in R : a \neq 0 \text{ and } ax = 0 \,\} \\ &=\; \{\, x \in M \mid \mathrm{ann}(x) \neq 0 \,\} \end{aligned}$$

If $x \in \mathrm{tor}(M)$ then x is said to be a **torsion element** of M. And M is said to be a **torsion module** iff $\mathrm{tor}(M) = M$ and M is said to be **torsion-free** (or **faithful**) iff $\mathrm{tor}(M) = \{0\}$. In other words that is: M is torsion-free, iff for any $a \in R$ and $x \in M$ we have the implication

$$ax \;=\; 0 \quad\Longrightarrow\quad a \;=\; 0 \;\text{ or }\; x \;=\; 0$$

Prob If M is torsion-free, suppose $ax = 0$: If $a = 0$ we are done, hence consider the case $a \neq 0$. By definition this is $x \in \mathrm{tor}(M) = \{0\}$ and hence $x = 0$. Conversely, if the implication holds, then $x \in \mathrm{tor}(M)$ implies $x =$ and hence $\mathrm{tor}(M) = \{0\}$.

(v) A sub-module $P \leq_{\mathsf{m}} M$ is said to be a **pure** sub-module of M, iff it satisfies one of the following three equivalent conditions

(a) $\mathrm{tor}(M/P) = \{\, 0 + P \,\}$

(b) $\mathrm{Hull}(P) = P$

(c) for any $a \in R$ with $a \neq 0$ and any $x \in M$ we get the implication

$$ax \in P \quad\Longrightarrow\quad x \in P$$

Prob for any $x \in M$ we have $x + P \in \mathrm{tor}(M/P)$ if and only if there is some $a \in R$ with $a \neq 0$ such that $a(x + P) = 0 + P$ and this again is $ax \in P$. Hence M/P is torsion-free if and only if $ax \in P$ implies $x + P = 0 + P$, which in turn is $x \in P$. So (a) and (c) are equivalent. Now $P \subseteq \mathrm{Hull}(P)$ is true in general and (c) is nothing but $\mathrm{Hull}(P) \subseteq P$, such that (c) also is equivalent to (b).

(3.21) Example:
Let $(R,+,\cdot)$ be any ring and $\mathfrak{a} \trianglelefteq_{\mathsf{i}} R$ be an ideal of R. Considering $M := R/\mathfrak{a}$ as an R-module we find the annihilator of M to be $\mathfrak{a}$ again

$$\operatorname{ann}\left(R\Big/_{\mathfrak{a}}\right) \;=\; \mathfrak{a}$$

Prob If $a \in \operatorname{ann}(R/\mathfrak{a})$ then in particular $0+\mathfrak{a} = 0 = a(1+\mathfrak{a}) = a+\mathfrak{a}$ such that $a \in \mathfrak{a}$. Conversely if $a \in \mathfrak{a}$ and $b+\mathfrak{a} \in R/\mathfrak{a}$ then $ab \in \mathfrak{a}$, as $\mathfrak{a}$ is an ideal. But this means $0 = 0+\mathfrak{a} = ab+\mathfrak{a} = a(b+\mathfrak{a})$.

(3.22) Proposition: (viz. 752)
Let $(R,+,\cdot)$ be any ring, M be an R-module and $X \subseteq M$ be an arbitrary subset of M. Then we obtain all of the following statements

(i) The annihilator of an arbitrary set X is a left-ideal of R, the annihilator of some sub-module $P \leq_{\mathsf{m}} M$ even is an ideal of R, formally that is

$$\begin{aligned} \operatorname{ann}(X) &\leq_{\mathsf{m}} R \\ \operatorname{ann}(P) &\trianglelefteq_{\mathsf{i}} R \end{aligned}$$

(ii) ($\diamondsuit$) Let $x \in M$ be any element of the R-module M and recall that the R-sub-module of M generated by $\{x\}$ is given to be $Rx = \{ax \mid a \in R\}$. Then we obtain the following isomorphy of R-modules

$$R\Big/_{\operatorname{ann}(x)} \;\cong_{\mathsf{m}}\; Rx \;:\; b+\operatorname{ann}(x) \;\mapsto\; bx$$

In particular: If $\mathfrak{a} \trianglelefteq_{\mathsf{i}} R$ is a proper ($\mathfrak{a} \neq R$) ideal, then it also is an annihilator $\mathfrak{a} = \operatorname{ann}(x)$ of some $x \in M$ iff there is a monomorphism ι of R-modules that maps $R/\mathfrak{a}$ into M

$$\mathfrak{a} \in \operatorname{Anns}(M) \iff \exists\, \iota : R\Big/_{\mathfrak{a}} \hookrightarrow M$$

(iii) Let $(S,+,\cdot)$ be a skew-field and M be an S-module, if now $0 \neq x \in M$ is a non-zero element of M, then the annihilator of x is 0. In particular M is torsion free and $S \xrightarrow{\sim} Sx : a \mapsto ax$ is an isomorphism of S-modules

$$\operatorname{ann}(x) \;=\; \begin{cases} S \text{ if } x = 0 \\ 0 \text{ if } x \neq 0 \end{cases}$$

(iv) Suppose R is a commutative ring, then the annihilator of X equals the annihilator of the R-sub-module generated by X, formally that is

$$\operatorname{ann}(X) \;=\; \operatorname{ann}\Big(\langle X\rangle_{\mathsf{m}}\Big)$$

Consequently if $\{x_i \mid i \in I\} \subseteq M$ is a set of generators of the R-module $M = \operatorname{Lh}\{x_i \mid i \in I\}$ then the annihilator of M is just

$$\operatorname{ann}(M) \;=\; \bigcap_{i\in I} \operatorname{ann}(x_i)$$

($\diamondsuit$) And the R-module homomorphism $\varphi : R \to M^I$ defined by $\varphi(a) := (ax_i)$ has the kernel $\mathrm{kn}(\varphi) = \mathrm{ann}(M)$. In particular we obtain an embedding (i.e. an injective R-module homomorphism)

$$R \Big/ \mathrm{ann}(M) \hookrightarrow M^I \ : \ a + \mathrm{ann}(M) \mapsto (ax_i)$$

(v) If $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is an ideal contained in the annihilator ideal $\mathfrak{a} \subseteq \mathrm{ann}(M)$ of M, then M can be turned into a $(R/\mathfrak{a})$-module using the following scalar-multiplication (where $a \in R$ and $x \in M$)

$$(a + \mathfrak{a})x \ := \ ax$$

(3.23) Proposition: (viz. 754)
Let $(R, +, \cdot)$ be any non-zero ring $R \neq 0$ and M be an R-module. Then we obtain the following statements

(i) If R is a integral domain, then the torsion sub-module $\mathrm{TOR}(M)$ truly is an R-sub-module of M

$$\mathrm{TOR}(M) \quad \leq_{\mathrm{m}} \quad M$$

and the quotient module of M modulo $\mathrm{TOR}(M)$ is torsion-free, put formally that is the equation

$$\mathrm{TOR}\left(M \Big/ \mathrm{TOR}(M)\right) \ = \ \{0\}$$

(ii) If R is an integral domain, M is a free R-module and $P \leq_{\mathrm{m}} M$ is any sub-module of M, then P already is torsion-free. Formally again

$$R \text{ integral domain, } M \text{ free} \implies \mathrm{TOR}(P) = 0$$

(iii) If $R \neq 0$ and $M \neq 0$ both are non-zero, then the following statements are equivalent (recall that in this case M was said to be *torsion-free*, resp. *faithful*)

(a) $\mathrm{ZD}_R(M) \subseteq \{0\}$

(b) $\mathrm{TOR}(M) = \{0\}$, where $0 \in M$

(c) $\mathrm{Anns}(M) = \{0\}$, where $0 = \{0\} \subseteq R$

(d) $\forall\, a \in R, \forall\, x \in M$ we get $ax = 0 \implies a = 0$ or $x = 0$

Nota if $M = 0$, then (a) and (d) are true, (b) is equivalent to $R \neq 0$, yet (c) is false, as $\mathrm{Anns}(M) = \emptyset$.

(iv) If M is a finitely generated module over the integral domain R, then the following two properties of M are equivalent

(a) M is torsion-free

(b) There is some $n \in \mathbb{N}$ such that M can be embedded into R^n. That is there is some monomorphism μ of R-modules of the form

$$\mu \ : \ M \ \hookrightarrow \ R^n$$

(v) ($\diamondsuit$) If N is another R-module and $\Phi : M \xrightarrow{\sim} N$ an isomorphism of R-modules, then we get $\Phi(\mathrm{tor}(M)) = \mathrm{tor}(N)$ and thereby obtain the following isomorphies of R-modules

$$\begin{aligned} \mathrm{tor}(M) &\xrightarrow{\sim} \mathrm{tor}(N) \quad : \quad x \mapsto \Phi(x) \\ M\big/_{\mathrm{tor}(M)} &\xrightarrow{\sim} N\big/_{\mathrm{tor}(N)} \quad : \quad x + \mathrm{tor}(M) \mapsto \Phi(x) + \mathrm{tor}(N) \end{aligned}$$

(vi) If $M \neq 0$ is a finitely generated, non-zero, torsion-free $\mathrm{tor}(M) = 0$ R-module, then M contains a maximal pure sub-module, formally this can be put as

$$\{\, P \leq_{\mathfrak{m}} M \mid P \neq M,\, P \text{ is pure} \,\}^* \neq \emptyset$$

(3.24) Proposition: (viz. 756)
Let $(R, +, \cdot)$ be a commutative ring and M be any R-module. Then we obtain the following statements

(i) If M is a simple, non-zero R-module, then the annihilator of M is a maximal ideal of R, formally

$$\mathrm{ann}(M) \in \mathrm{Smax}(R)$$

(ii) If $x \in M$ is any element of M, then $\mathrm{ann}(x)$ is a prime ideal if and only if for any $a \in R$ we either have $ax = 0$ or $\mathrm{ann}(ax) = \mathrm{ann}(x)$. That is the following two statements are equivalent

(a) $\mathrm{ann}(x)$ is a prime ideal of R

(b) $\forall\, a \in R$ we get $\mathrm{ann}(ax) = R$ or $\mathrm{ann}(ax) = \mathrm{ann}(x)$

(iii) Let $x \in M$ be any element of M, such that $\mathfrak{p} := \mathrm{ann}(x) \in \mathrm{Spec}(R)$ is a prime ideal of R. Then for any $a \in R \setminus \mathfrak{p}$ and $y := ax$ the sub-module $Ry \leq_{\mathfrak{m}} M$ only has a single annihilator ideal

$$\mathrm{Anns}(Ry) = \{\, \mathfrak{p} \,\}$$

(iv) If $R \neq 0$ is non-zero, then maximal annihilator ideals of M are prime ideals of R. Formally that is

$$\big(\mathrm{Anns}(M)\big)^* \subseteq \mathrm{Spec}(R)$$

(3.25) Definition: (viz. 757)
Let $(R, +, \cdot)$ be any ring and M be an R-module. Also let $P, Q \leq_{\mathfrak{m}} M$ be any two sub-modules of M, then we define the **ideal quotient** $Q : P$ to be the following subset of R

$$Q : P := \{\, a \in R \mid aP \subseteq Q \,\} \leq_{\mathfrak{m}} R$$

Nota thereby $Q : P \leq_{\mathfrak{m}} R$ is an R-sub-module of R and also we get $\mathrm{ann}(M) = 0 : M$. In particular, if R is commutative $Q : P \trianglelefteq_{\mathfrak{i}} R$ truly is an ideal, as the name suggests and in this case we also get $\mathrm{ann}(x) = 0 : Rx$ for any $x \in M$.

3.3 Direct Sums

(3.26) Definition:
Let $(R,+,\cdot)$ be an arbitrary ring and consider an R-module M. If we are given finitely many sub-modules $P_1,\dots,P_n \leq_{\mathfrak{m}} M$ of M, then we define their **sum** to be set of all sums of elements of the P_i

$$P_1+\cdots+P_n \;:=\; \{\, x_1+\cdots+x_n \mid x_i\in P_i \,\}$$

If we are given an arbitrary collection of R-sub-modules $P_i \leq_{\mathfrak{m}} M$, where $i\in I$ is any index set, then we generalize the finite case directly by defining the **sum** of the P_i to be the set of all *finite* sums of elements of the P_i, that is

$$\sum_{i\in I} P_i \;:=\; \bigcup_{n=1}^{\infty} \left\{ x_1+\cdots+x_n \;\middle|\; \{\, i(1),\dots,i(n)\,\}\subseteq I,\; x_k\in P_{i(k)} \right\}$$

By definition this set consists of finite sums of elements $x_1+\cdots+x_n$ where $x_k\in P_{i(k)}$ for some $i(k)\in I$. Thus if we denote the collection of finite subsets of I by $\mathcal{I}:=\{\,\Omega\subseteq I \mid \#\Omega<\infty\,\}$ then we may present a slightly more formal description of this set

$$\sum_{i\in I} P_i \;=\; \left\{ \sum_{i\in\Omega} x_i \;\middle|\; \Omega\in\mathcal{I},\; x_i\in P_i \right\}$$

(3.27) Remark:

(i) Suppose we are given a collection of elements $(x_i)\subseteq M$ such that for any $i\in I$ we have $x_i\in P_i$. More importantly suppose that among these x_i only finitely many are non-zero, that is the set $\Omega:=\{\,i\in I \mid x_i\neq 0\,\}$ is finite. As in (1.26) we then denote

$$\sum_{i\in I} x_i \;:=\; \sum_{i\in\Omega} x_i$$

That is: If only finitely many of the x_i are non-zero, then there is a well-defined notion of the sum of these elements - just leave out the zeros and sum up these (finitely many) non-zero elements.

(ii) It is clear that $P_1+\cdots+P_n$ and - more generally - $\sum_i P_i$ are sub-modules of M. Prob Given any $x=\sum_i x_i$ and $y=\sum_i y_i\in\sum_i P_i$ their sum is $x+y=\sum_i(x_i+y_i)$ and as P_i is a sub-module this means $x_i+y_i\in P_i$ and hence $x+y\in\sum_i P_i$ again. Likewise for any $a\in R$ we have $ax=\sum_i(ax_i)\in\sum_i P_i$, as also $ax_i\in P_i$.

(iii) In fact, in the light of proposition (3.12) this is just the R-sub-module of M generated by the P_i, i.e. $P_1+\cdots+P_n=\langle P_1\cup\cdots\cup P_n\rangle_{\mathfrak{m}}\leq_{\mathfrak{m}} M$. More generally: Given an arbitrary collection of R-sub-modules $P_i\leq_{\mathfrak{m}} M$, where $i\in I$ is any index set, then the sum of the P_i is just the sub-module generated by the union of all the P_i

$$\sum_{i\in I} P_i \;=\; \langle \bigcup_{i\in I} P_i\rangle_{\mathfrak{m}}$$

(iv) In particular, if $x \in M$ is any single element, then the sub-module $\langle\{ x \}\rangle_{\mathsf{m}}$ of M generated by x is $\langle\{ x \}\rangle_{\mathsf{m}} = \mathrm{Lh}_R\{ x \} = Rx := \{ ax \mid a \in R \}$. Generally for any $x_1, \ldots, x_n \in M$ the R-linear hull is just the set of all linear combinations $a_1x_1 + \cdots + a_nx_n \in M$ for some $a_1, \ldots, a_n \in R$

$$\mathrm{Lh}_R\{ x_1, \ldots, n_n \} \quad = \quad Rx_1 + \cdots + Rx_n$$

Even more generally, as the R-linear hull and the sum of sub-modules are based on finite sums only, it is clear that for an arbitrary collection of elements $(x_i) \subseteq M$ the linear hull of the x_i is just the the sum of the sub-modules generated by the x_i, formally that is

$$\mathrm{Lh}_R\{ x_i \mid i \in I \} \quad = \quad \sum_{i \in I} Rx_i$$

(v) If we are given a chain (P_i) of sub-modules, that is $P_i \leq_{\mathsf{m}} M$ is a sub-module for any $i \in I$ such that for any $i, j \in I$ we have $P_i \subseteq P_j$ or $P_j \in P_i$, then even the union of the P_i itself (not only their sum) is a sub-module of M

$$\bigcup_{i \in I} P_i \quad \leq_{\mathsf{m}} \quad M$$

Prob consider $a \in R$ and $x, y \in P$ where we abbreviate $P = \bigcup_i P_i$. That is $x \in P_i$ and $y \in P_j$ for some i resp. $j \in I$. Without loss of generality we may assume $P_i \subseteq P_j$ and that is $x \in P_j$ as well. Then as P_i and $P_j \leq_{\mathsf{m}} M$ are sub-modules again we clearly have $ax \in P_i$ and $x + y \in P_j$ such that ax and $x + y \in P$ again. That is P truly is a sub-module of M again.

(3.28) Example:
Sadly the summation and intersection of modules do not fit together nicely. This is to say: if we are given sub-modules P and $Q_i \leq_{\mathsf{m}} M$ of an R-module M, then in general we only get

$$P + \bigcap_{i \in I} Q_i \quad \subseteq \quad \bigcap_{i \in I} (P + Q_i)$$

Yet the equality of these sets need not hold true. As an example we regard the ring $R := \mathbb{Z}$ and pick up the $\mathbb{Z}$-module $M := \mathbb{Z}$ again. If now $P := 2\mathbb{Z}$ and for any $i \in I = \{ i \in \mathbb{N} \mid i \geq 3, i \text{ prime} \}$ we let $Q_i := i\mathbb{Z}$, then it is clear, that $P + Q_i = M$ for any $i \in I$ [as $2\mathbb{Z} + i\mathbb{Z} = \gcd(2, i)\mathbb{Z} = \mathbb{Z}$ due to the lemma (2.83) of Bezout]. However if $x \in Q_i$ for any $i \in I$, then $i \mid x$, such that x would have infinitely many prime divisors. This forces $x = 0$ and hence the intersection $\bigcap_i Q_i = 0$. Therefore we only have

$$P + \bigcap_{i \in I} Q_i \quad = \quad 2\mathbb{Z} \quad \subset \quad \mathbb{Z} \quad = \quad \bigcap_{i \in I} (P + Q_i)$$

(3.29) Definition: (viz. 758)

- Let $(R, +, \cdot)$ be any ring, $I \neq \emptyset$ be a non-empty index set and for any $i \in I$ let M_i [more explicitly $(M_i, +, \diamond)$] be an R-module. Then we regard the cartesian product of the M_i

$$M \quad := \quad \prod_{i \in I} M_i$$

This can be turned into another R-module - called the **(exterior) direct product** of the M_i - by installing the following (point-wise) algebraic operations (where $x = (x_i)$, $y = (y_i) \in M$ and $i \in I$)

$$\begin{aligned} + &: M \times M \to M \quad : \quad (x,y) \mapsto (x_i + y_i) \\ \diamond &: R \times M \to M \quad : \quad (a,x) \mapsto (ax_i) \end{aligned}$$

Note that $x_i + y_i$ is the addition of vectors in M_i and ax_i is the scalar multiplication in M_i and hence these operations are well-defined. It is easy to see that M thereby inherits the properties of an R-module.

- We have just introduced the direct product M of the M_i as an R-module. Let us now define a certain R-sub-module of M, called the **(exterior) direct sum** of the M_i. To do this let us first denote the *support* of $x = (x_i) \in M$ to be $\mathrm{Supp}(x) := \{\, i \in I \mid x_i \neq 0 \in M_i \,\} \subseteq I$, i.e. the set of indexes i with non-vanishing x_i. Then we let

$$\bigoplus_{i\in I} M_i \;:=\; \left\{ x \in \prod_{i\in I} M_i \;\middle|\; \#\mathrm{Supp}(x) < \infty \right\}$$

That is $\bigoplus_i M_i$ consists of all the $x = (x_i) \in \prod_i M_i$ that contain finitely many non-zero coefficients $x_i \neq 0$ only. In particular the direct sum coincides with the direct product if and only if I is finite

$$\bigoplus_{i\in I} M_i \;=\; \prod_{i\in I} M_i \quad\Longleftrightarrow\quad \#I < \infty$$

Generally $\bigoplus_i M_i$ becomes an R-module again under the same algebraic operations that we have introduced for the direct product $\prod_i M_i$. Formally that is: The exterior direct sum is an R-sub-module of the exterior direct product

$$\bigoplus_{i\in I} M_i \quad \leq_{\mathsf{m}} \quad \prod_{i\in I} M_i$$

- If for any $i \in I \neq \emptyset$ we are even given an R-semi-algebra A_i then the (exterior) direct product $A := \prod_i A_i$ of the A_i is an R-semi-algebra again, under the point-wise multiplication

$$\cdot \;:\; A \times A \to A \;:\; (x,y) \mapsto (x_i y_i)$$

where, as before, $x_i y_i$ is the multiplication in A_i. Also the exterior direct sum $\oplus_i A_i$ of the A_i is a sub-semi-algebra of A again. And if for any $i \in I$ we even have an R-algebra A_i with unit element $1_i \in I$ then the exterior direct product $\prod_i A_i$ is an R-algebra, too having the unit element $1 = (1_i)$.

- $(\diamondsuit)$ Let now N be another R-module and for any $i \in I$ consider an R-module homomorphism $\varphi_i : M_i \to N$. Then we obtain a well-defined R-module-homomorphism from the direct sum to N

$$\bigoplus_{i\in I} \varphi_i \;:\; \bigoplus_{i\in I} M_i \to N \;:\; (x_i) \mapsto \sum_{i\in I} \varphi_i(x_i)$$

This is well-defined, as only finitely many $x_i \in M_i$ are non-zero [as (x_i) is contained in the direct *sum* of the M_i] and hence the sum only contains finitely many non-zero summands. And the properties of an R-module-homomorphism are trivially inherited from the φ_i.

- Now consider any R-module M and for any $i \in I$ an R-sub-module $P_i \leq_{\mathsf{m}} M$. And for any $j \in I$ let us denote by $\widehat{P}_j$ the R-sub-module generated by all P_i except P_j, formally we denote

$$\widehat{P}_j \;:=\; \sum_{i \neq j} P_i \;=\; \langle \bigcup_{i \in I \setminus \{j\}} P_i \rangle_{\mathsf{m}}$$

Then M is said to be the **(inner) direct sum** of the P_i iff the set $\{ P_i \mid i \in I \}$ of these sub-modules satisfies one of the following two equivalent statements

(a) The P_i build up M as their sum, but for any index $j \in I$ the intersection of P_j and its complement $\widehat{P}_j$ is trivial. Formally these are the statements

$$M = \sum_{i \in I} P_i \quad \text{and} \quad \forall\, j \in I : P_j \cap \widehat{P}_j = 0$$

(b) Any $x \in M$ has a representation as a (finite) sum of uniquely determined elements $x_i \in P_i$ (where $i \in I$). Formally this reads as

$$\forall\, x \in M \;\; \exists !\, (x_i) \in \prod_{i \in I} P_i \;\; : \;\; x = \sum_{i \in I} x_i$$

And in case that M is the inner direct sum ot the P_i we will use the following notation to express this fact (beware the similarity to the exterior direct sum above)

$$M \;=\; \bigoplus_{i \in I} P_i$$

- Let M be any R-module and $P \leq_{\mathsf{m}} M$ and R-sub-module again. Then P is said to be **complemented** or a **direct summand** of M, iff there is another sub-module $\widehat{P}$ of M, such that M is the inner direct sum of P and $\widehat{P}$. Formally that is: $\exists\, \widehat{P} \leq_{\mathsf{m}} M$ such that

(1) $M = P + \widehat{P}$
(2) $P \cap \widehat{P} = 0$

(3.30) Remark: (viz. 759)
Recall that in cartesian products (and the direct product has been defined as such) for any $j \in I$ there is a *canonical projection* π_j of the product $\prod_i M_i$ onto M_j. Thereby the projection π_j is defined, to be

$$\pi_j \;:\; \prod_{i \in I} M_i \to M_j \;:\; (x_i) \mapsto x_j$$

But in contrast to arbitrary cartesisan products we also find (for any $j \in I$) a *canonical embedding* ι_j into the direct sum (and product), by letting

$$\iota_j \;:\; M_j \to \bigoplus_{i \in I} M_i \;:\; x_j \mapsto (\delta_{i,j} x_j)$$

where $\delta_{i,j}x_j := x_j$ for $i = j$ and $\delta_{i,j}x_j := 0 \in M_i$ for $i \neq j$. Then it is clear that $\pi_j\iota_j = \mathbb{1}$ is the identity on M_j and in particular π_j is surjective and ι_j is injective. Further these maps are tightly interwoven with the structure of the direct product and sum respectively. To be precise, consider any $x = (x_i) \in \prod_i M_i$, then x is precisely the I-tuple of its projections

$$x \;=\; \Big(\pi_i(x)\Big)$$

On the other hand for any $x = (x_i) \in \bigoplus_i M_i$ we obtain another identity (note that the sum thereby is well-defined, as only finitely many x_i are non-zero, such that in truth the sum is a finite only)

$$x \;=\; \sum_{i\in I} \iota_i(x_i)$$

($\diamondsuit$) By definition of the operations on the direct product/sum it is also clear that both projection π_j and embedding ι_j are homomorphisms of R-modules, as the operations on the sum/product are component-wise.

(3.31) Example:
Consider any ring $(R, +, \cdot)$, the R-module $M := R^2$ and the sub-modules $P_1 := R(1,0) = \{\, (a,0) \mid a \in R \,\}$ and $P_2 := R(0,1) = \{\, (0,b) \mid b \in R \,\}$. Then clearly M is the inner direct sum of P_1 and P_2

$$M \;=\; P_1 \oplus P_2$$

To check whether M can be decomposed as a direct sum of some P_i it does *not* suffice to verify, that the intersection of the P_i is pairwise trivial. In the example above let $P_3 := R(1,1) = \{\, (a,a) \mid a \in R \,\}$. Then it is clear that $M = P_1 + P_2 + P_3$ and $P_i \cap P_j = 0$ for any $i \neq j \in 1 \ldots 3$, but M is *not* the inner direct sum of P_1, P_2 and P_3. In fact $x = (1,1) \in M$ has non-unique representations as $x = (1,0) + (0,1) \in P_1 + P_2$ and as $x = (1,1) \in P_3$.

(3.32) Example:
The most common example of a direct sum of modules is a simple multiple of a single module: To be precise, let $(R, +, \cdot)$ be some ring and consider an R-module M. Then for any non-empty set I we denote the product (resp. sum) of one copy of M for any $i \in I$ by

$$\begin{aligned} M^I \;&:=\; \prod_{i\in I} M \;&=\; \{\, (x_i) = x : I \to M : i \mapsto x_i \,\} \\ M^{\oplus I} \;&:=\; \bigoplus_{i\in I} M \;&=\; \Big\{\, (x_i) \in M^I \mid \{\, i \in I \mid x_i \neq 0 \,\} \text{ is finite} \,\Big\} \end{aligned}$$

The most important example is the case $M = R$ of the base ring itself. That is $R^{\oplus I}$ which consists of I identical copies of R. By definition the operations on M^I (and $M^{\oplus I}$) are component-wise, that is for any (x_i), $(y_i) \in M^I$ and any $a \in R$ we have

$$\begin{aligned} (x_i) + (y_i) \;&=\; (x_i + y_i) \\ a(x_i) \;&=\; (ax_i) \end{aligned}$$

A special case of this is M^n - here we take n identical copies of M, where $1 \leq n \in \mathbb{N}$ is any natural number. In the formal terms above this can be put as M^I, where the set is $I = 1 \ldots n$. As I is finite there is no difference between the direct sum and product

$$M^n \;:=\; M^{1\ldots n} \;=\; \prod_{i=1}^{n} M \;=\; \bigoplus_{i=1}^{n} M$$

$(\diamondsuit)$ The rest of this section will be devoted to studying the interaction of homorphisms of modules and direct sums, resp. to compare the structures of different direct sums using isomorphisms. While we only need the very basic notions of homorphisms of modules, these will be introduced in section 3.8 only. Thus the reader is asked to familiarize himself with homo- and isomorphisms beforehand.

(3.33) Remark:
There is a reason why we didn't bother to strictly separate exterior and inner direct products. The reason simply is: There is not much of a difference to begin with, any inner direct product already is an exterior direct product (up to isomorphy) and any exterior direct product can be reformulated as an interior direct product. We will give a precise formulation of this fact in the proposition below. Thus the distinction between inner and exterior is a purely set-theoretic one, it doesn't affect the algebra involved. This is why we do not bother that our formalism doesn't really distinguish between the interior and exterior direct sums - the difference is no structural one. (In general group theory there *will be* a difference, however).

(3.34) Proposition: (viz. 759)

(i) $(\diamondsuit)$ Let $(R, +, \cdot)$ be any ring, M be an R-module and $P_i \leq_{\mathfrak{m}} M$ be an arbitrary ($i \in I$) collection of R-sub-modules of M. If now M is the inner direct sum $M = \bigoplus_i P_i$ of the P_i, then M is already isomorphic (as an R-module) to the exterior direct sum of the P_i under the isomorphism

$$\bigoplus_{i\in I} P_i \;\cong_{\mathfrak{m}}\; M \quad : \quad (x_i) \mapsto \sum_{i\in I} x_i$$

(ii) Let $(R, +, \cdot)$ be any ring and M_i an arbitrary ($i \in I$) collection of R-modules. Now let $M := \bigoplus_i M_i$ be the exterior direct product of these modules and let $P_i := \iota_i(M_i) \leq_{\mathfrak{m}} M$ be the embedding of P_i into M. Then M is just the interior direct sum of the P_i put formally, that is

$$\bigoplus_{i\in I} M_i \;=\; \bigoplus_{i\in I} P_i$$

(3.35) Proposition: (viz. 760)
Let $(R, +, \cdot)$ be any ring and M be an R-module. For an arbitrary index set I and any $i \in I$ let $M_i \leq_{\mathfrak{m}} M$ be a sub-module, such that M is the inner direct product of the M_i

$$M \;=\; \bigoplus_{i\in I} M_i$$

For any $i \in I$ also let $P_i \leq_{\mathsf{m}} M_i$ be a sub-module of M_i and take P to be the sum of these. Then $P \leq_{\mathsf{m}} M$ is a sub-module of M, that also is the inner direct sum of the P_i, formally

$$P := \sum_{i\in I} P_i = \bigoplus_{i\in I} P_i$$

and we obtain an isomorphism of R-modules from the exterior direct sum of the quotient modules M_i/P_i to the quotient module M/P by virtue of

$$\bigoplus_{i\in I} M_i \Big/ P_i \xrightarrow{\sim} M \Big/ P \,:\, (x_i + P_i) \mapsto \left(\sum_{i\in I} x_i\right) + P$$

(3.36) Remark:
If $P \leq_{\mathsf{m}} M$ is a sub-module and $P_i := M_i \cap P$, then we always get the inclusion $\sum_i P_i \subseteq P$ however these need not be equal. Thus the above proposition cannot be reformulated starting with $P \leq_{\mathsf{m}} M$.

As an example regard $M = \mathbb{Q}^2$, then clearly $M = M_1 \oplus M_2$ where $M_1 = \mathbb{Q}(1,1)$ and $M_2 = \mathbb{Q}(1,-1)$. If now $P = \mathbb{Q} \times \{0\} \subseteq M$ then clearly $P_1 = M_1 \cap P = 0$ and $P_2 = M_2 \cap P = 0$. Thus we have $P_1 + P_2 \subset P$ and hence cannot apply the proposition above.

(3.37) Proposition: (viz. 760)
Let $(R, +, \cdot)$ be an arbitrary ring and let I and J be arbitrary index sets. For any $i \in I$ resp. $j \in J$ let M_i and N_j be R-modules. Then we obtain the following isomorphy of R-modules

$$\mathsf{mhom}\left(\bigoplus_{i\in I} M_i, \prod_{j\in J} N_j\right) \cong_{\mathsf{m}} \prod_{(i,j)\in I\times J} \mathsf{mhom}(M_i, N_j)$$

We can even give the above isomorphism explictly: let us denote the direct sum of the M_i by $M := \bigoplus_i M_i$ and the direct product of the N_j by $N := \prod_j N_j$. Further denote the canonical embedding $\iota_i : M_i \to M$ and the canonical projection $\pi_j : N \to N_j$. Then the isomorphy explictly reads as

$$\begin{array}{rcl} \mathsf{mhom}(M,N) & \cong_{\mathsf{m}} & \displaystyle\prod_{(i,j)\in I\times J} \mathsf{mhom}(M_i, N_j) \\ \varphi & \mapsto & \left(\pi_j \varphi \iota_i\right) \\ \left(\displaystyle\bigoplus_{i\in I} \varphi_{i,j}\right) & \mapsfrom & \left(\varphi_{i,j}\right) \end{array}$$

Let us explain this compact notation a bit: for any $(I \times J)$-tupel of homomorphisms $\varphi_{i,j} : M_i \to N_j$ the corresponding homomorphism $\varphi := (\bigoplus_i \varphi_{i,j}) = (\sum_i \varphi_{i,j}\pi_i)$ is explicitly given to be the following:

$$\varphi \,:\, M \to N \,:\, (x_i) \to \left(\sum_{i\in I} \varphi_{i,j}(x_i)\right)$$

(3.38) Remark:
Suppose we even have $(\varphi_{i,j}) \in \prod_i \bigoplus_j \mathrm{mhom}(M_i, N_j)$, that is for any $i \in I$ the set $\left\{ j \in J \mid \varphi_{i,j} \neq 0 \right\}$ is finite. Then the induced map φ even lies in $(\bigoplus_i \varphi_{i,j}) \in \mathrm{mhom}(\bigoplus_i M_i, \bigoplus_j N_j)$. The converse need not be true however, as an example regard $I = 0$, $J = \mathbb{N}$, $M = R^{\oplus\mathbb{N}}$ and $N_j = R$. As a homomorphism φ we choose the identity $\varphi = \mathbb{1} : R^{\oplus\mathbb{N}} \to R^{\oplus\mathbb{N}}$. Then φ induces the tuple $\mathbb{1} \mapsto (\pi_j)$, which has no finite support.

3.4 Ideal-induced Modules

In this short section we will introduce the concept of the sub-module $\mathfrak{a}M$ generated by an ideal $\mathfrak{a}$ of R. This is a way of passing on from a module M over a ring R to a related module over the quotient ring $R/\mathfrak{a}$. So as always with going to quotients, one tries to single out unnecessary complications, solve the problem in the reduced case and later lift it up again, solving the original problem. This is particularly useful in case the quotient ring $R/\mathfrak{m}$ is a field, i.e. $\mathfrak{m}$ is a maximal ideal.

While the construction is elementary it yields some very useful results - primarily the lemma of Nakayama. Though these results are of little value in their own right, they are powerful tools in providing proofs of more substantial theorems. Hence one might as well skip this section and postpone it, until one encounters the urge to use a quotient construction.

(3.39) Definition:
Consider an arbitrary ring $(R,+,\cdot)$, an ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ and an R-module M. Let further $P \leq_{\mathfrak{m}} M$ be a sub-module of M, then we denote the sub-module of M generated by elements of the form ap, for some $a \in \mathfrak{a}$ and $p \in P$, by

$$\mathfrak{a}P \;:=\; \langle \{\, ap \mid a \in \mathfrak{a},\ p \in P \,\} \rangle_{\mathfrak{m}}$$

(3.40) Proposition: (viz. 762)
Let $(R,+,\cdot)$ be an arbitrary ring, $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ an ideal and consider a sub-module $P \leq_{\mathfrak{m}} M$ of the R-module M. Then we get the statements

(i) The sub-module $\mathfrak{a}P$ of M can be given explicitly, to be the following subset of M

$$\mathfrak{a}P \;=\; \left\{ \sum_{i=1}^{n} a_i p_i \;\middle|\; 1 \leq n \in \mathbb{N},\ a_i \in \mathfrak{a},\ p_i \in P \right\}$$

(ii) If P is generated by $\{\, p_j \mid j \in J \,\} \subseteq P$ (for some arbitrary index set J), then for any $x \in \mathfrak{a}P$ there are some $n \in \mathbb{N}$, some $a_1, \ldots, a_n \in \mathfrak{a}$ and $p_1, \ldots, p_n \in \{\, p_j \mid j \in J \,\}$ such that x can be written as

$$x \;=\; a_1 p_1 + \cdots + a_n p_n$$

If R is commutative and $\mathfrak{a}$ is generated by $\{\, a_i \mid i \in i \,\} \subseteq \mathfrak{a}$ (for some arbitrary index set I), then for any $x \in \mathfrak{a}P$ there are some $n \in \mathbb{N}$, some $a_1, \ldots, a_n \in \{\, a_i \mid i \in i \,\}$ and $p_1, \ldots, p_n \in P$ such that x can be written in the same way, as above.

(iii) Due to its definition $\mathfrak{a}P$ is a sub-module of P and thereby we obtain the following chain of inclusions

$$\mathfrak{a}P \quad \leq_{\mathfrak{m}} \quad P \quad \leq_{\mathfrak{m}} \quad M$$

(iv) Both the assignments $\mathfrak{a} \mapsto \mathfrak{a}P$ and $P \mapsto \mathfrak{a}P$ are order preserving, that is given any two ideals $\mathfrak{a}$ and $\mathfrak{b} \trianglelefteq_{\mathfrak{i}} R$ resp. any two sub-modules P and $Q \leq_{\mathfrak{m}} M$ we obtain the following implications

$$\mathfrak{a} \subseteq \mathfrak{b} \quad \Longrightarrow \quad \mathfrak{a}P \subseteq \mathfrak{b}P$$

$$P \subseteq Q \implies \mathfrak{a}P \subseteq \mathfrak{a}Q$$

(v) Going to residues modulo P is compatible with inducing modules by ideals, that is given $P \leq_{\mathsf{m}} M$ and $\mathfrak{a} \trianglelefteq_{\mathsf{i}} R$ we get the following equality of sub-modules of M/P

$$\mathfrak{a}\left(M\Big/_P\right) = P + \mathfrak{a}M\Big/_P$$

(vi) The quotient module $M/\mathfrak{a}M$ becomes a well-defined $(R/\mathfrak{a})$-module under the following operations: For any $a \in R$ and $x, y \in M$ we let

$$\begin{aligned}(x + \mathfrak{a}M) + (y + \mathfrak{a}M) &:= (x + y) + \mathfrak{a}M\\ (a + \mathfrak{a})(x + \mathfrak{a}M) &:= (ax) + \mathfrak{a}M\end{aligned}$$

(vii) $(\diamondsuit)$ If M and N are R-modules and $\varphi : M \to N$ is an homomorphism of R-modules, then we obtain a well-defined homomorphism of $(R/\mathfrak{a})$-modules, by letting

$$\varphi\Big/_{\mathfrak{a}} : M\Big/_{\mathfrak{a}M} \to N\Big/_{\mathfrak{a}N} : x + \mathfrak{a}M \mapsto \varphi(x) + \mathfrak{a}N$$

If φ is surjective or bijective, then so is the induced homomorphism $\varphi/\mathfrak{a}$. That is if $\star$ abbreviates any of the words *surjective* or *bijective* then we obtain the implication

$$\varphi \text{ is } \star \implies \varphi\Big/_{\mathfrak{a}} \text{ is } \star$$

Nota $\varphi/\mathfrak{a}$ not necessarily inherits the injectivity of φ. E.g. consider $R = \mathbb{Z}$ and $\mathfrak{a} = 3\mathbb{Z}$. Then $\mathbb{Z} \to \mathbb{Q} : k \mapsto k$ clearly is injective, but $\mathfrak{a}\mathbb{Q} = \mathbb{Q}$ such that $\mathbb{Q}/\mathfrak{a}\mathbb{Q} = 0$ and hence the induced map $\mathbb{Z}/\mathfrak{a}\mathbb{Z} \to \mathbb{Q}/\mathfrak{a}\mathbb{Q}$ cannot be injective.

(viii) Thereby the linear hull of any subset $Z \subseteq M/\mathfrak{a}M$ of the quotient module does not depend on whether we take R or $R/\mathfrak{a}$ as a base ring, that is

$$\mathsf{Lh}_R(Z) = \mathsf{Lh}_{R/\mathfrak{a}}(Z)$$

(ix) Hence a subset $Q \subseteq M/\mathfrak{a}M$ of the quotient module is an R-sub-module of $M/\mathfrak{a}M$ iff it is an $(R/\mathfrak{a})$-sub-module of $M/\mathfrak{a}M$. Therefore the $(R/\mathfrak{a})$-sub-modules of $M/\mathfrak{a}M$ are given to be

$$\mathsf{Subm}_{R/\mathfrak{a}}\left(M\Big/_{\mathfrak{a}M}\right) = \left\{ P\Big/_{\mathfrak{a}M} \;\middle|\; P \leq_{\mathsf{m}} M,\ \mathfrak{a}M \subseteq P \right\}$$

(x) $(\diamondsuit)$ If $\mathfrak{a}, \mathfrak{b} \trianglelefteq_{\mathsf{i}} R$ are ideals of R such that $\mathfrak{a} \subseteq \mathfrak{b}$, then we also get $\mathfrak{a}M \subseteq \mathfrak{b}M$ and thereby the third isomorphism theorem of modules grants the following isomorphy of R-modules

$$M\Big/_{\mathfrak{b}M} \xrightarrow{\sim} M/\mathfrak{a}M\Big/_{\mathfrak{b}M/\mathfrak{a}M} : x + \mathfrak{b}M \mapsto (x + \mathfrak{b}M) + \mathfrak{b}M\Big/_{\mathfrak{a}M}$$

(3.41) Example: (viz. 878)
Let $(R,+,\cdot)$ be a commutative ring and fix any ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$. Then for any non-empty set I, the induced sub-module $\mathfrak{a}R^{\oplus I}$ is nothing but the direct sum $\mathfrak{a}^{\oplus I}$ of I copies of $\mathfrak{a}$

$$\mathfrak{a}R^{\oplus I} \;=\; \mathfrak{a}^{\oplus I}$$

And thereby we obtain an isomorphy of the $(R/\mathfrak{a})$-modules $R^{\oplus I}/\mathfrak{a}R^{\oplus I}$ and $(R/\mathfrak{a})^{\oplus I}$ which can be given explictly, to be the following

$$\left(R \Big/ \mathfrak{a}\right)^{\oplus I} \xrightarrow{\sim} R^{\oplus I} \Big/ \mathfrak{a}R^{\oplus I} \;:\; (b_i + \mathfrak{a}) \mapsto (b_i) + \mathfrak{a}R^{\oplus I}$$

(3.42) Example:
Consider an R-module M a scalar $t \in R$ and sub-modules $P, Q \leq_{\mathfrak{m}} M$. It might be tempting to think that $tQ \subseteq P \subseteq Q$ might yield $P = Q$ - under some reasonable assumptions - as this clearly is true, if R is a skew-field. However this is *not* the case: Instead we find that

$$4\,\mathbb{Z}^2 \;\subset\; \mathbb{Z}\begin{pmatrix}1\\3\end{pmatrix} + \mathbb{Z}\begin{pmatrix}3\\1\end{pmatrix} \;\subset\; \mathbb{Z}^2$$

So here R is a PID (the next best thing after a field), $\mathbb{Z}^2$ is a free, finitely generated module and the generators of P are primitive - refer to (5.26) for a definition. So even in this case $P = Q$ is untrue.

Prob Let us abbreviate $Q := \mathbb{Z}^2$ and $P := \mathbb{Z}(1,3) + \mathbb{Z}(3,1)$. As $(1,3)+(3,1) = (4,4)$ we have $4Q \subseteq P$. But $P \neq Q$, as $(1,0) \notin P$. To see this assume $a(1,3) + b(3,1) = (1,0)$. This would mean $a + 3b = 1$ and $3a + b = 0$. Subtracting the 2nd from the 1st equation we find $-2a + 2b = 1$ which is $2(b-a) = 1$. This would mean $2 \mid 1$ which is untrue.

(3.43) Proposition: (viz. 815)
Let $(R,+,\cdot)$ be a commutative ring and $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ be an ideal of R. We regard the polynomial ring $R[t]$ as an R-module, as well. Then we get the following properties:

(i) Let $\mathfrak{a}R[t]$ be sub-module of $R[t]$ induced by $\mathfrak{a}$ [note that this is the same, as the push out of the ideal $\mathfrak{a}$ to $R[t]$ in the sense of (8.12)]. Then we find the identity

$$\mathfrak{a}R[t] \;=\; \mathfrak{a}[t] \;:=\; \{\, f \in R[t] \mid \forall\, k \in \mathbb{N} : f[k] \in \mathfrak{a} \,\}$$

(ii) Let us also denote $\widetilde{\mathfrak{a}} := \mathfrak{a}[t] + tR[t] = \{\, f \in R[t] \mid f(0) \in \mathfrak{a} \,\}$, then we obtain two isomorphisms of rings, of the following forms

$$R[t] \Big/ \mathfrak{a}[t] \xrightarrow{\sim} \left(R \Big/ \mathfrak{a}\right)[t] \;:\; f + \mathfrak{a}[t] \mapsto \sum_{k=0}^{\infty} (f[k] + \mathfrak{a})\, t^k$$
$$R[t] \Big/ \widetilde{\mathfrak{a}} \xrightarrow{\sim} R \Big/ \mathfrak{a} \;:\; f + \widetilde{\mathfrak{a}} \mapsto f(0) + \mathfrak{a}$$

(iii) If $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$ is a prime ideal, then $\mathfrak{p}[t] \trianglelefteq_{\mathfrak{i}} R[t]$ is a prime ideal, as well. And if $\mathfrak{m} \trianglelefteq_{\mathfrak{i}} R$ is a maximal ideal, then $\widetilde{\mathfrak{m}} \trianglelefteq_{\mathfrak{i}} R[t]$ is a maximal ideal, as well.

(3.44) Lemma: (viz. 968) ($\diamondsuit$)
Let $(R, +, \cdot)$ be a commutative ring, $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be an ideal and consider an R-module M. Then the following statements are true:

(i) If M is a free R-module, with basis $\{ m_i \mid i \in I \}$, then the quotient module $M/\mathfrak{a}M$ is a free $(R/\mathfrak{a})$-module having the basis

$$\{ m_i + \mathfrak{a}M \mid i \in I,\ m_i \notin \mathfrak{a}M \}$$

And thereby the elements of this basis are pairwise distinct. To be precise: If the m_i are pairwise distinct (i.e. for any j, $j \in I$ we get $m_i = m_j \implies i = j$) then the $m_i + \mathfrak{a}M$ are pairwise distinct too, for any i, $j \in I$ with m_i and $m_j \notin \mathfrak{a}M$ we get

$$m_i + \mathfrak{a}M = m_j + \mathfrak{a}M \quad \Longrightarrow \quad i = j$$

(ii) *Lemma of Nakayama:* Given any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ of R the following two statements are equivalent:

(a) $\mathfrak{a} \subseteq \operatorname{JAC}(R)$

(b) For any finitely generated R-module M we get $\mathfrak{a}M = M \implies M = 0$

(iii) If $P \leq_{\mathrm{m}} M$ is a sub-module of M, such that the quotient module M/P is finitely generated, and $\mathfrak{a} \subseteq \operatorname{JAC}(R)$, then we obtain the implication:

$$M = P + \mathfrak{a}M \quad \Longrightarrow \quad P = M$$

(iv) If N is another R-module, and $\varphi : M \to N$ is an R-module-homomorphism, such that $N/\operatorname{im}(\varphi)$ is finitely generated. If again $\mathfrak{a} \subseteq \operatorname{JAC}(R)$, then we get the following equivalence

$$\varphi \text{ is surjective} \quad \Longleftrightarrow \quad \varphi\big/_{\mathfrak{a}} \text{ is surjective}$$

(v) If M is finitely generated, $\varphi : M \to M$ even is an R-module-endomorphism, and again $\mathfrak{a} \subseteq \operatorname{JAC}(R)$, then we get the following equivalence

$$\varphi \text{ is bijective} \quad \Longleftrightarrow \quad \varphi\big/_{\mathfrak{a}} \text{ is bijective}$$

(vi) *Lemma of Dedekind:* If M is a finitely generated R-module, such that $\mathfrak{a}M = M$, then the ideal $\mathfrak{a}$ contains some element $a \in \mathfrak{a}$ such that $1 - a$ annihilates M. That is

$$(1 - a)M \ = \ 0$$

(3.45) Proposition: (viz. 994)
Let $(R,+,\cdot)$ be a commutative ring and consider an R-module M. Then we obtain the following statements

(i) Suppose that M is finitely generated, that is there are some elements $x_1,\ldots,x_n \in M$ such that $M = \mathrm{Lh}_R\{\, x_1,\ldots,x_n \,\}$. If $\mathfrak{m}M = 0$ for any maximal ideal $\mathfrak{m} \trianglelefteq_{\mathfrak{i}} R$, then M already has to be the zero-module. Formally that is the implication

$$\forall\, \mathfrak{m} \in \mathrm{Smax}(R) : M = \mathfrak{m}M \quad\Longrightarrow\quad M = 0$$

(ii) Suppose $P \leq_{\mathfrak{m}} M$ is a *cofinite* module, that is there are some elements $x_1,\ldots,x_n \in M$ such that $M = P + \mathrm{Lh}_R\{\, x_1,\ldots,x_n \,\}$. Then we get the implication

$$\forall\, \mathfrak{m} \in \mathrm{Smax}(R) : M = P + \mathfrak{m}M \quad\Longrightarrow\quad P = M$$

(iii) If N is another R-module and $\varphi : M \to N$ is an R-module-homomorphism such that $\mathrm{im}(\varphi) \leq_{\mathfrak{m}} N$ is cofinite (i.e. $M = \mathrm{im}(\varphi) + \mathrm{Lh}_R\{\, x_1,\ldots,x_n \,\}$ for some $x_1,\ldots,x_n \in M$). Then we get the equivalence

$$\varphi \text{ is surjective} \quad\Longleftrightarrow\quad \forall\, \mathfrak{m} \in \mathrm{Smax}(R) \;:\; \varphi\big/_{\mathfrak{m}} \text{ is surjective}$$

(iv) If M is finitely generated and $\varphi : M \to M$ is an R-module-endomorphism of M, then we get the following equivalence of

$$\varphi \text{ is bijective} \quad\Longleftrightarrow\quad \forall\, \mathfrak{m} \in \mathrm{Smax}(R) \;:\; \varphi\big/_{\mathfrak{m}} \text{ is bijective}$$

A special case of the above are principal ideals $\mathfrak{a} = tR$, i.e. ideals that are generated by a single element $t \in R$ only. In this case it is clear, that $\mathfrak{a}M = tM := \{\, tx \mid x \in M \,\}$. In other words tM is the image of the endomorphism $x \mapsto tx$ of M. Its kernel will be denoted by M_t and in this sense tM and M_t are two sides of the same coin. Let us take a closer look at this particular coin:

(3.46) Proposition: (viz. 765)
Let $(R,+,\cdot)$ be a commutative ring and fix an element $t \in R$. Let M be an R-module and consider the scalar multiplication by t from the left

$$\mu_t \;:\; M \to M \;:\; x \mapsto tx$$

Let us denote $M_t := \mathrm{kn}(\mu_t) = \{\, x \in M \mid tx = 0 \,\}$ the sub-module of elements of M that are annihilated by t. Then we obtain the following statements:

(i) M_t becomes an (R/tR)-module under its own addition and the well-defined scalar multiplication

$$(a + tR)x \;:=\; ax$$

(ii) If we denote $tM := \mathrm{im}(\mu_t) = \{\, tx \mid x \in M \,\}$, then tM is a sub-module of M, as well, and we obtain the following isomorphy of R-modules

$$M \Big/ M_t \xrightarrow{\sim} tM \,:\, x + M_t \mapsto tx$$

(iii) If M and N are R-modules and $\varphi : M \to N$ is a homomorphism of R-modules, then we have the inclusion of sets: $\varphi(M_t) \subseteq N_t$. And if φ is bijective then we even get the equality $\varphi(M_t) = N_t$.

(iv) If $P_i \leq_{\mathsf{m}} M$ is a family (where $i \in I$) of sub-modules of M, such that M is the inner direct sum of the P_i, then M_t also is the inner direct sum of the sub-modules $(P_i)_t \leq_{\mathsf{m}} M_t$, formally

$$M = \bigoplus_{i \in I} P_i \quad \Longrightarrow \quad M_t = \bigoplus_{i \in I} (P_i)_t$$

(v) $(\diamondsuit)$ Consider some $a_i \in R$ for any $i \in I$ (where I is any non-empty index set), let $b_i := ta_i$ for some fixed $t \in R$ and suppose we have a homomorphism of the form

$$\varphi \,:\, \bigoplus_{i \in I} R \Big/ b_i R \,\to\, M$$

Then there also is the following, well-defined homomorphism $t\varphi$. If φ is surjective and I is finite, then $t\varphi$ is surjective. And if φ is injective and $t \in \mathrm{NZD}(R)$ is a non-zero-divisor, then $t\varphi$ is injective

$$t\varphi \,:\, \bigoplus_{i \in I} R \Big/ a_i R \,\to\, tM \,:\, \Big(r_i + a_i R\Big) \,\mapsto\, \varphi\Big(tr_i + b_i R\Big)$$

(vi) Consider r, s and $t \in R$ such that $t = rs$ and regard the quotient ring $Q := R/tR$ as an R-module. Let $Q_s := \{\, q \in Q \mid sq = 0 \,\}$ again, then we obtain a well-defined homomorphism of R-modules via

$$R \Big/ sR \to \Big(R \Big/ tR\Big)_s \,:\, a + sR \mapsto ra + tR$$

And if $t \in \mathrm{NZD}(R)$ is a non-zero-divisor, this homomorphism already is an isomorphism of R-modules.

(vii) If s, $t \in R$ are any elements of R, as in (vi) we regard $Q := R/tR$ as an R-module and its sub-module $Q_s := \{\, q \in Q \mid sq = 0 \,\}$. Then we find $Q_s = Q$ if and only if t divides s. Formally

$$\Big(R \Big/ tR\Big)_s = R \Big/ tR \quad \Longleftrightarrow \quad t \mid s$$

(viii) If t, $p \in \mathrm{NZD}(R)$ are non-zero-divisors of R, such that p also is a prime element of R, then we obtain the following equivalence (the implication " $\Longleftarrow$ " remains true for arbitrary elements $t \in R$)

$$\Big(R \Big/ tR\Big)_p = 0 \quad \Longleftrightarrow \quad p \not| \, t$$

3.5 Block Decompositions

Algebras - being modules - can often be decomposed into direct sums of sub-modules. However they also carry a multiplicative structure, so the question arises how these two structures interact with one and another. It will turn out, that certain elements of algebras even provide a decomposition by multiplication. This analysis will then be used to study the structure of a group G by studying the structure of the group algebra $F[G]$. This method will be called *representation theory*, so we are about to establish some parts of the machinery for this theory here.

(3.47) Definition:
Let $(R, +, \cdot)$ be an arbitrary ring, M be an R-module and A be an R-algebra. Then we define the following notions for R, M and A respectively:

(i) M is said to be a **simple** R-module if the only sub-modules of M are the trivial ones (0 and M). Formally M is simple, iff the following implication holds true

$$P \leq_{\mathfrak{m}} M \implies P = 0 \text{ or } P = M$$

(ii) M is said to be an **indecomposable** R-module if it does not admit a decomposition as an inner direct sum into non-trivial sub-modules. Formally M is indecomposable iff for any two sub-modules $P, Q \leq_{\mathfrak{m}} M$ the following implication holds true

$$M = P \oplus Q \implies P = 0 \text{ or } Q = 0$$

(iii) M is said to be **completely reducible** if there are some sub-modules $M_i \leq_{\mathfrak{m}} M$ (where $i \in I$) such that all the M_i are simple R-modules and M can be decomposed as the inner direct sum

$$M = \bigoplus_{i \in I} M_i$$

(iv) R is said to be a **simple** ring, if the only ideals of R are the trivial ones (0 and R). Formally R is simple, iff the following implication holds true

$$\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R \implies \mathfrak{a} = 0 \text{ or } \mathfrak{a} = R$$

(v) R is said to be an **indecomposable** ring if it does not admit a decomposition (as an inner direct sum of R-modules) into non-trivial ideals. Formally R is indecomposable iff for any two ideals $\mathfrak{a}$, $\mathfrak{b} \trianglelefteq_{\mathfrak{i}} R$ the following implication holds true

$$R \cong_{\mathfrak{m}} \mathfrak{a} \oplus \mathfrak{b} \implies \mathfrak{a} = 0 \text{ or } \mathfrak{b} = 0$$

(vi) A is said to be a **simple** R-algebra, if the only algebra-ideals of A are the trivial ones (0 and A), Formally A is simple, iff the following implication holds true

$$\mathfrak{a} \trianglelefteq_{\mathfrak{a}} A \implies \mathfrak{a} = 0 \text{ or } \mathfrak{a} = A$$

(vii) A is said to be an **indecomposable** R-algebra if it does not admit a decomposition (as an inner direct sum of R-algebras) into non-trivial, unital sub-algebras. Formally A is indecomposable iff for any two unital subalgebras $U, V \leq_{\mathfrak{b}} A$ the following implication holds true

$$A \cong_{\mathfrak{a}} U \oplus V \implies U = 0 \text{ or } V = 0$$

(ix) A is said to be **completely reducible** if there are some sub-semi-algebras $U_i \leq_{\mathfrak{b}} A$ (where $i \in I$) such that all the U_i are unital and simple R-algebras and A is isomorphic to the exterior direct product of these U_i. That is, iff

$$A \cong_{\mathfrak{a}} \prod_{i \in I} U_i$$

(3.48) Remark:

- If R is commutative then any sub-module $\mathfrak{a} \leq_{\mathfrak{m}} R$ already is an ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$. Hence a commutative ring R is a simple R-module if and only if it is simple as a ring. And likewise a commutative ring R is indecomposable as a ring if and only if it is indecomposable as an R-module.
- Recall that a sub-semialgebra $U \subseteq A$ is said to be *unital* if there is some $e \in U$ such that for any $f \in U$ we get $ef = f = fe$. That is U is an R-algebra with unit element e. If now $U_i \leq_{\mathfrak{b}} A$ is a family of unital sub-semi-algebras, where U_i has the unit element e_i, then $\prod_i U_i$ is an R-algebra with unit element (e_i). Note that this (e_i) is *not* contained in $\oplus_i U_i$ unless I is finite. But in this case the direct product $\prod_i U_i$ and sum $\oplus_i U_i$ are just the same, anyway.

(3.49) Proposition: (viz. 996)
Let $(R, +, \cdot)$ be any non-zero ring $R \neq 0$ and consider two R-modules M and N. Also let $x, y \in M$ be any non-zero elements $x, y \neq 0$. Then we get

(i) M is a simple R-module if and only if all non-zero elements of M already generate M as an R-module. Formally the latter property reads as

$$\forall\, x \in M \,:\, x \neq 0 \implies M = Rx$$

(ii) If $M = Rm$ is a *cyclic* R-module, i.e. it is generated by some element $m \in M$, then M is simple, if and only if $\operatorname{ann}(m) \leq_{\mathfrak{m}} R$ is a maximal R-sub-module of R, that is iff

$$\operatorname{ann}(m) \neq R \quad \text{and} \quad \forall\, P \leq_{\mathfrak{m}} R : \operatorname{ann}(m) \subseteq P \implies \operatorname{ann}(m) = P$$

(iii) If R is a commutative ring and M is a simple R-module, then for any two non-zero elements $0 \neq x, y \in R$ share the same annihilator and this is a maximal ideal of R

$$\operatorname{ann}(x) = \operatorname{ann}(y) \in \operatorname{Smax}(R)$$

(iv) If R is a commutative ring, M is a simple R-module and $0 \neq x, y \in M$ are any two non-zero elements of M, then there is an R-module-automorphism $\Phi : M \xrightarrow{\sim} M$ such that $\Phi(x) = y$

$$\exists\, \Phi \in \mathrm{maut}(M) \;:\; \Phi(x) = y$$

(v) *Lemma of Schur I:* If both M and N are simple R-modules, then any non-zero R-module-homomorphisms form M to N has to be an isomorphism. Formally that is

$$\forall\, \varphi \in \mathrm{mhom}(M,N) \;:\; \varphi \neq 0 \quad\Longrightarrow\quad \varphi \text{ is bijective}$$

(vi) *Lemma of Schur II:* If M is a simple R-module, then the ring $\mathrm{mend}(M)$ of R-module-endomorphism already is a division ring (under composition as multiplication). In particular we get

$$\mathrm{mend}(M) \;=\; \mathrm{maut}(M) \cup \{0\}$$

(vii) If R is a commutative ring, M is a simple R-module and $\varphi : M \to M$ is an R-module-endomorphism, then there is some $a \in R$ such that φ is given to be $\varphi(x) = ax$ (for any $x \in M$).

(3.50) Definition:
Let $(R, +, \cdot)$ be an arbitrary ring and A be an R-semi-algebra. Further consider any three elements x, y and $z \in A$, then we define the following relations on A

$$\begin{aligned} x \perp y \quad &:\Longleftrightarrow \quad xy = 0 \text{ and } yx = 0 \\ z = x \oplus y \quad &:\Longleftrightarrow \quad (x \perp y) \text{ and } z = x + y \end{aligned}$$

Also recall that the **center** $\mathrm{CEN}(A)$ of A is the set of all elements of A, that commute with all others. And $e \in A$ is said to be an **idempotent** of A iff $e^2 = e$. A **central idempotent** thereby is an element $e \in A$ that commutes with all other elements and is an idempotent. That is we define

$$\begin{aligned} \mathrm{CEN}(A) &:= \{\, x \in A \mid \forall\, y \in A : xy = yx \,\} \\ \mathrm{IP}(A) &:= \{\, e \in A \mid e^2 = e \,\} \\ \mathrm{CIP}(A) &:= \mathrm{CEN}(A) \cap \mathrm{IP}(A) \\ \mathrm{SIP}(A) &:= \{\, s \in \mathrm{CIP}(A) \mid s \text{ is simple} \,\} \end{aligned}$$

Thereby an element $s \in A$ is said to be **simple** iff it is a central idempotent such that for any two central idempotents e, $f \in \mathrm{CIP}(A)$ we get the implication

$$s = e \oplus f \quad\Longrightarrow\quad e = 0 \text{ or } f = 0$$

Finally a subset $B \subseteq A$ is said to be a **block** of A if there is some $s \in A$ such that (1) s is simple and (2) B is of the form $B = As = \{\, xs \mid x \in A \,\}$.

(3.51) Proposition: (viz. 998)
Let $(R,+,\cdot)$ be an arbitrary ring and let $A \neq 0$ be a non-zero R-algebra. Then we obtain the properties:

(i) If $B = Ae \subseteq A$ for some central idempotent $e \in \mathrm{CIP}(A)$, we find that B already is (a) an R-sub-semi-algebra $B \leq_{\mathrm{b}} A$ of the A-algebra A, (b) an ideal $B \trianglelefteq_{\mathrm{i}} A$ of the semi-ring A and (c) an R-algebra with unit element $1_B = e$.

(ii) Suppose A is an R-algebra, that is it contains a unit element and thereby even is a ring. Then $\mathrm{CEN}(A) \leq_{\mathrm{a}} A$ is an R-subalgebra and multiplicatively closed subset of A.

(iii) If A is an R-algebra again and $e \in A$ is a (central) idempotent, then $1-e \in A$ is a (central) idempotent as well and we get $e \perp (1-e)$.

(3.52) Proposition: (viz. 998)
Let $(R,+,\cdot)$ be an arbitrary ring and $A \neq 0$ be a non-zero R-algebra, then we obtain the properties:

(i) Suppose the elements $e_1,\ldots,e_n \in A$ have the following properties: (1) $e_1+\cdots+e_n = 1$, (2) $e_i^2 = e_i$ for all $i \in 1\ldots n$ and (3) $e_ie_j = 0$ for all $i \neq j \in 1\ldots n$. Then any $x \in A$ can be written as $x = xe_1+\cdots+xe_n$ and hence A can be decomposed as an inner direct sum of A-sub-modules

$$A \;=\; \bigoplus_{i=1}^{n} Ae_i$$

(ii) If $e_1,\ldots,e_n \in \mathrm{CIP}(A)$ even are central idempotents of A such that (1) $e_1+\cdots+e_n = 1$ and (2) $e_ie_j = 0$ for all $i \neq j \in 1\ldots n$ then the above decomposition respects the multiplication. That is

$$P_i \;:\; A \twoheadrightarrow Ae_i \;:\; x \mapsto xe_i$$

is an epimorphism of A-algebras satisfying $P_i^2 = P_i$ and $P_iP_j = 0$ for any $i \neq j \in 1\ldots n$. The image $\mathrm{im}(P_i) = Ae_i$ not only is an A-sub-module of A, but also a ring with unit element e_i. And the kernel of P_i is given to be the following R-sub-algebra of A

$$\mathrm{kn}(P_i) \;=\; \sum_{j\neq i} Ae_j$$

Therefore we obtain an isomorphy of the R-algebras A and the (exterior) direct sum $Ae_1 \oplus \cdots \oplus Ae_n$

$$A \;\xrightarrow{\sim}\; \bigoplus_{i=1}^{n} Ae_i \;:\; x \mapsto (xe_i)$$

(iii) If A is free, as an R-module then the canonical map $R \hookrightarrow A : a \mapsto a1_A$ is injective and there is an R-submdule $A' \leq_{\mathrm{m}} A$ such that A can be decomposed into an inner direct sum of R-sub-modules

$$A \;=\; R1_A \oplus A'$$

(3.53) Example:

(i) If $e \in \text{IP}(A)$ is a central idempotent of A, then by (3.51.(i)) $1-e \in \text{IP}(A)$ is a central idempotent again, with $e \perp (1-e)$. And according to (3.52.(i)) this yields the decomposition

$$A \;=\; Ae \oplus A(1-e)$$

(ii) Consider an arbitrary ring $(R,+,\cdot)$ and the the R-algebra $A := R^n$ under the point-wise operations $(x_i)+(y_i) = (x_i+y_i)$ and $(x_i)\cdot(y_i) = (x_i \cdot y_i)$. Then R^n has the Euclidean basis $e_j := (\delta_{i,j}) \in R^n$ (where $j \in 1 \ldots n$) and these obviously satisfies $e_i e_j = \delta_{i,j} e_j$. Clearly any $x = (x_i) \in R^n$ can be written uniquely as $x = \sum_i x_i e_i$ such that we have the basis decomposition of R^n

$$R^n \;=\; Re_1 \oplus \ldots \cdots \oplus Re_n$$

And this is just the decomposition of (3.52.(i)) again. Note that other bases of R^n need not yield a decomposition, that is compatible with the multiplication of R^n, as this is due to $e_i e_j = \delta_{i,j} e_j$.

(iii) Now let $(R,+,\cdot)$ be a commutative ring and regard the R-algebra $A = \text{mat}_n(R)$. As in (ii) above let $e_j := (\delta_{i,j}) \in R^n$ (where $j \in 1 \ldots n$) be the Euclidean basis of R^n and let $E_j := E_{j,j} = \text{dia}(e_j)$ be the diagonal matrix of e_j. That is

$$E_1 \;=\; \begin{pmatrix} 1 & 0 & \cdots & 0 \\ 0 & 0 & & \vdots \\ \vdots & & \ddots & \vdots \\ 0 & \cdots & \cdots & 0 \end{pmatrix} \quad \text{up to} \quad E_n \;=\; \begin{pmatrix} 0 & \cdots & \cdots & 0 \\ \vdots & \ddots & & \vdots \\ \vdots & & 0 & 0 \\ 0 & \cdots & 0 & 1 \end{pmatrix}$$

Then we get $E_1 + \cdots + E_n = \mathbb{1}_n$ and $E_i E_j = \delta_{i,j} E_j$ again such that by (3.52.(i)) we find a decomposition of the R-algebra of $(n \times n)$-matrices

$$\text{mat}_n(R) \;=\; \text{mat}_n(R)E_1 \oplus \cdots \oplus \text{mat}_n(R)E_n$$

Thereby for any $(n \times n)$-matrix $X = (x_{i,j}) \in \text{mat}_n(R)$ it is obvious, that XE_j is just the matrix with a copy of the j-th column of X in it, that is

$$XE_1 \;=\; \begin{pmatrix} x_{1,1} & 0 & \cdots & 0 \\ \vdots & \vdots & \ldots & \vdots \\ x_{n,1} & 0 & \cdots & 0 \end{pmatrix} \quad \text{up to} \quad XE_n \;=\; \begin{pmatrix} 0 & \cdots & 0 & x_{1,n} \\ \vdots & \ldots & \vdots & \vdots \\ 0 & \cdots & 0 & x_{n,n} \end{pmatrix}$$

(3.54) Theorem: (viz. 999)
Let $(R, +, \cdot)$ be a commutative ring and $A \neq 0$ be a non-zero R-algebra. Then we obtain the following two lists of equivalences

(i) We obtain the following equivalences for A being indecomposable as an R-module

(a) A is indecomposable as an A-module

(b) If $e, f \in \text{IP}(A)$ are idempotents of A with $e \perp f$ and $e + f = 1$ then we get $e = 0$ or $f = 0$.

(c) $\text{IP}(A) = \{ 0, 1 \}$

(ii) We obtain the following equivalences for A being indecomposable as an R-algebra

(a) A is indecomposable as an R-algebra

(b) $\text{CEN}(A)$ is indecomposable as an R-algebra

(c) A is a block, that is $A = As$ for some simple $s \in A$

(d) $1 \in A$ is a simple element

(e) $\text{CIP}(A) = \{ 0, 1 \}$

3.6 Dependence Relations

In algebra there are two separate notions of dependence: *Linear dependence* and *algebraic dependence*. A subset S of a module is linearly dependent, if we can find a linear equation with elements of S that turns out 0. A subset S of an algebra is algebraically dependent, if we can find a polynomial equation with elements of S that turns out 0.
Linear dependence yields the notion of a *basis* of a module and we will see that the module's structure is determined by its basis. The same is true with algebraic dependence: This yields the notion of a *transcendence basis*, which determines the structure of the algebra.
It is customary to approach these problems directly and hence separately. Yet there is the underlying concept of *dependence*. So we will try a little more abstract approach: First we will introduce the general notion of a *dependence relation*. Then we will prove (among others) that any dependence relation admits a basis. This will be accomplished in this section.
Consequently it suffices to show that linear dependence (over a skew-field) is a dependence relation, respectively that algebraic dependence (over a field) is a dependence relation. This will be discussed in the sections to come. This approach features the advantage that it neatly separates set-theoretic and algebraic concepts, which yields beautiful clarity and pinpoints precisely where the (skew-)field is involved.

(3.55) Definition:
Let M be an arbitrary set. We will regard relations $\vdash$ of between subsets and elements of M. That is relations of the form $\vdash \subseteq \mathcal{P}(M) \times M$. And for any such relation, elements $x \in M$ and subsets S, $T \subseteq M$ we will use the following notations

$$\begin{aligned} S \vdash x &:\iff (S,x) \in \vdash \\ S \nvdash x &:\iff \neg(S \vdash x) \\ \langle S \rangle &:= \{\, x \in M \mid S \vdash x \,\} \\ \mathrm{sub}(M) &:= \{\, \langle S \rangle \mid S \subseteq M \,\} \\ T \vdash S &:\iff S \subseteq \langle T \rangle \\ &\iff \forall\, x \in S : T \vdash x \end{aligned}$$

Now $\vdash$ is said to be a **dependence relation** on M, iff it is of the form $\vdash \subseteq \mathcal{P}(M) \times M$ and for any elements x, $y \in M$ and subsets S, $T \subseteq M$ it satisfies the following four properties:

(D1) Any element x of S already depends on S, formally this can be put as

$$x \in S \implies S \vdash x$$

(D2) If x depends on S and S depends on T, then x already depends on T

$$T \vdash S,\ S \vdash x \implies T \vdash x$$

(D3) If x depends on S, then it already depends on a finite subset S_x of S

$$S \vdash x \implies \exists\, S_x \subseteq S \,:\, \#S_x < \infty \text{ and } S_x \vdash x$$

(D4) If x depends on S, but not on $S \setminus \{ s \}$ (for some $s \in S$), then we can replace s by x in S, to find a dependency of s on the modified set, formally that is the implication

$$S \vdash x, \text{ and } S \setminus \{ s \} \nvdash x \implies \Big((S \setminus \{ s \}) \cup \{ x \} \Big) \vdash s$$

Equivalently this can be put in the following, technically easier (but a little less intuitive), form: If y depends on $S \cup x$, but not on S alone, then x depends on $S \cup \{ y \}$

$$S \cup \{ x \} \vdash y, \text{ and } S \nvdash y \implies S \cup \{ y \} \vdash x$$

And in case that $\vdash$ is a dependence relation on M we further introduce the following notions: A subset $S \subseteq M$ is said to be **independent** (or more precisely $\vdash$*independent*), iff it satisfies

$$\forall s \in S \ : \ S \setminus \{ s \} \nvdash s$$

Clearly S is said to be **dependent** (or more precisely $\vdash$*dependent*), iff it is not independent (that is $S \setminus \{ s \} \vdash s$ for some $s \in S$). And a subset $B \subseteq M$ is said to be a **basis** (or more precisely a $\vdash$*basis*) iff it is independent and generates M. Formally B is a basis, iff it satisfies

(B1) B is independent

(B2) and $\langle B \rangle = M$

(3.56) Remark:
Let M be any set, such that $\vdash$ is a dependence relation on M and $P \subseteq M$ be any subset of M. Then clearly P inherits this dependence relation: That is for any subset $S \subseteq P$ and any $x \in P$ the relation $S \vdash x$ is a dependence relation again (between the subsets and elements of P).

Prob By construction the restricted relation $S \vdash_P x$ is defined by $S \subseteq P$ and $x \in P$ and $S \vdash x$. As $S \vdash x$ satisfies (D1) to (D4) for *any* $S \subseteq M$ and $x \in M$ these property are in particular satisfied, for those subsets $S \subseteq M$ with $S \subseteq P$ and those elements $x \in M$ with $x \in P$.

(3.57) Lemma: (viz. 866)
Let M be an arbitrary set, $S, T \subseteq M$ be arbitrary subsets and $\vdash$ be a dependence relation on M. Then we obtain all of the following statements

(i) The generation of subsets under $\vdash$ preserves the inclusion of sets, i.e.

$$S \subseteq T \implies \langle S \rangle \subseteq \langle T \rangle$$

(ii) Recall that we denoted $\mathrm{sub}(M)$ to be the set of all $\langle T \rangle$ for some subset $T \subseteq M$. Then for any subset $S \subseteq M$ we obtain the identities

$$\langle \langle S \rangle \rangle = \langle S \rangle = \bigcap \{ P \in \mathrm{sub}(M) \mid S \subseteq P \}$$

(iii) For any subset $S \subseteq M$ the following three statements are equivalent

(a) S is $\vdash$dependent

(b) $\forall\, T \subseteq M : S \subseteq T \implies T$ is $\vdash$dependent

(c) $\exists\, S_0 \subseteq S$ such that $\#S_0 < \infty$ and S_0 is $\vdash$dependent

(iv) For any subset $T \subseteq M$ the following three statements are equivalent

(a) T is $\vdash$independent

(b) $\forall\, S \subseteq M : S \subseteq T \implies S$ is $\vdash$independent

(c) $\forall\, T_0 \subseteq T$ we get $\#T_0 < \infty \implies T_0$ is $\vdash$independent

(v) For any $S \subseteq M$ and $x \in M$ the following statements are equivalent

(a) S is $\vdash$independent and $S \nvdash x$

(b) $S \cup \{ x \}$ is $\vdash$independent and $x \notin S$

(vi) Let $S_i \subseteq M$ be a chain (where $i \in I$) of $\vdash$idependent subsets of M, then the union of the S_i is $\vdash$independent again. Formally that is the implication

$$\left.\begin{array}{lcl} \forall\, i \in I & : & S_i \text{ is } \vdash\text{independent} \\ \forall\, i, j \in I & : & S_i \subseteq S_j \text{ or } S_j \subseteq S_i \end{array}\right\} \implies \bigcup_{i \in I} S_i \text{ is } \vdash\text{independent}$$

(vii) Let $S \subseteq M$ be an $\vdash$independent subset and $T \subseteq M$ be a subset, that generates M, i.e. $M = \langle T \rangle$. If now $S \subseteq T$, then there is a basis B in between S and T. Formally there is some $B \subseteq X$ with

(1) $S \subseteq B \subseteq T$ and

(2) B is a $\vdash$basis of M

(viii) Let $B \subseteq M$ be a $\vdash$basis of M, $b \in B$ and $x \in M$ be arbitrary. Then we denote the set B with b replaced by x by $B' := (B \setminus \{ b \}) \cup \{ x \}$. Then we find the implication

$$B' \vdash b \quad \implies \quad B' \text{ is a } \vdash\text{basis of } M$$

(ix) A subset $B \subseteq M$ is a $\vdash$basis of M if and only if it is a minimal $\vdash$generating subset of M. And this again is equivalent to being a maximal $\vdash$independent subset. Formally that is the equivalence of

(a) B is a $\vdash$basis of M

(b) B generates M (that is $M = \langle B \rangle$) and for any $S \subseteq M$ we obtain

$$S \subset B \quad \implies \quad M \neq \langle S \rangle$$

(c) B is $\vdash$independent and for any $S \subseteq M$ we obtain the implication

$$B \subset S \quad \implies \quad S \text{ is not } \vdash\text{independent}$$

(x) *Basis Exchange Theorem:* Let $B \subseteq M$ be a basis of M and consider an arbitrary subset $A \subseteq B$. Also let $A' \subseteq M$ be a set of elements, satisfying (1) A' is $\vdash$independent and (2) A' generates $\langle A' \rangle = \langle A \rangle$ the same subset, as A. Then we also find

$$\big(B \setminus A\big) \cup A' \text{ is a basis of } M$$

(xi) All $\vdash$bases of M have the same number of elements, formally that is

$$A, B \subseteq M \vdash \text{bases of } M \implies |A| = |B|$$

(xii) If $S \subseteq M$ is $\vdash$independent and $B \subseteq M$ is an $\vdash$basis of M, then S contains no more elements than B, that is $|S| \leq |B|$. Likewise, if $T \subseteq M$ generates $M = \langle T \rangle$, then T contains at least as many elements as B, that is $|B| \leq |T|$.

(xiii) Consider an $\vdash$independent subset $S \subseteq M$ and a $\vdash$basis $B \subseteq M$ of M. Further assume that $\#B < \infty$ is finite, then the following two statements are equivalent

(a) $|S| = |B|$

(b) S is an $\vdash$basis of M

Nota that in the proof of this lemma we did not always require all the properties of a dependence relation. Namely (i), (ii), (iii), (iv), the implication (a) $\implies$ (b) in (v), (vi) and the equivalence (a) $\iff$ (b) in (ix) require the relation $\vdash$ to satisfy properties (D1), (D2) and (D3) only.

(3.58) Remark:
In item (vii) we may chose $S = \emptyset$, as this always is $\vdash$independent respectively $T = M$, as always $M = \langle M \rangle$. These special choices yield the so called *basis selection* respectively *basis completion theorems* (the converse implications follow immediately from (i) and (ii) respectively). And as these are used frequently let us append them here. Thus suppose M is an arbitrary set and $\vdash$ is a dependence relation on M again. Then we get

- *Basis Selection Theorem*: a subset $T \subseteq M$ contains a $\vdash$basis of M if and only if it generates M, that is equivalent are

 (a) $\langle T \rangle = M$

 (b) $\exists\, B \subseteq T \,:\, B$ is a $\vdash$basis of M

- *Basis Completion Theorem*: a subset $S \subseteq M$ can be extended to a $\vdash$basis of M if and only if S is $\vdash$independent, that is equivalent are

 (a) S is $\vdash$independent

 (b) $\exists\, B \subseteq M \,:\, S \subseteq B$ and B is a $\vdash$basis of M

3.7 Linear Dependence

The primary task of any algebraic theory is to classify the objects involved. The same is true for module theory: What types of modules do exist? Surprisingly the answer will strongly depend on the module's base ring. A first complete answer can be given in the case that the base ring is a skew-field S, then all modules over S are of the form $S^{\oplus I}$ for some index set I. (We will later also find complete answers in case the base ring is a PID or DKD. But this is how far the theory carries).
In order to achieve this result we will have to define the notion of a *basis* of a module. Modules with basis will be said to be *free*. However most of the work is done already - all we have to do is prove that *linear dependence* truly is a *dependence relation*, as we have introduced it in the section before.

(3.59) Definition:
Let $(R,+,\cdot)$ be an arbitrary ring an M be R-module. Further consider an arbitrary subset $X \subseteq M$. Then we introduce the following notions

(i) A subset $X \subseteq M$ is said to **generate M as an R-module** (or simply to **R-generate M**), iff the R-module generated by X is M. Formally that is iff (where we also recalled proposition (3.12))

$$M \;=\; \langle X\rangle_{\mathsf{m}} \;=\; \left\{ \sum_{i=1}^{n} a_i x_i \;\middle|\; 1 \leq n \in \mathbb{N},\ a_i \in R,\ x_i \in X \right\}$$

Now X is said to ba a **minimal** R-generating set, iff X R-generates M but any proper subset of X does not R-generate M. Formally X is a minimal R-generating set, iff

$$\forall\, W \subseteq M \;:\; W \subset X \implies \langle W\rangle_{\mathsf{m}} \neq M$$

(ii) We thereby define the **rank** - denoted by $\operatorname{rank}(M)$ - to be the minimal cardinality of any R-generating subset X of M there is. Formally that is

$$\operatorname{rank}(M) \;:=\; \min\{\, |X| \mid X \subseteq M,\ \langle X\rangle_{\mathsf{m}} = M \,\}$$

Nota that this is well defined, as the cardinal numbers are well-ordered - that is any non-empty set of cardinal numbers has a minimal element. Also the defining set above is non-empty, as $M \subseteq M$ and $M = \langle M\rangle_{\mathsf{m}}$. In particular we have $\operatorname{rank}(M) \leq |M|$. Hence this definition yields the following properties: If $I = \operatorname{rank}(M)$ then we get

(1) there is some $X = \{\, x_i \mid i \in I \,\} \subseteq M$ such that $M = \langle X\rangle_{\mathsf{m}}$, and

(2) for any $Y \subseteq M$ with $M = \langle Y\rangle_{\mathsf{m}}$ there is some injective map $\iota : I \hookrightarrow Y$ from I into Y.

(iii) M is said to be **finitely generated**, iff it is R-generated by some finite subset $X \subseteq M$. That is iff M satisfies one of the two following equivalent conditions

(a) $\operatorname{rank}(M) < \infty$

(b) $\exists\, X \subseteq M : \#X < \infty$ and $M = \langle X\rangle_{\mathsf{m}}$

(iv) A sub-module $P \leq_{\mathsf{m}} M$ is said to be **cofinite** (in M), iff you only need to add finitely many to generate M. Formally P is cofinite, iff it satisfies one of the following two equivalent conditions

(a) M/P is finitely generated

(b) $\exists\, X \subseteq M : \#X < \infty$ and $M = P + \langle X \rangle_{\mathsf{m}}$

Nota if $X = \{ x_1, \ldots, x_n \}$ such that $M = P + \langle X \rangle_{\mathsf{m}}$, then it is clear that M/P is generated by the set $\{ x_i + P \mid i \in 1 \ldots n \}$. Vice versa, if $\{ x_i + P \mid i \in 1 \ldots n \}$ generates M/P, then we get $M = P + \langle X \rangle_{\mathsf{m}}$, by taking $X = \{ x_1, \ldots, x_n \}$. Let us prove this: Given any $x \in M$ there are $a_i \in R$ such that $x + P = a_1 x_1 + \cdots + a_n x_n + P$ and hence $x = p + a_1 x_1 + \cdots + a_n x_n \in P + \langle X \rangle_{\mathsf{m}}$ for some $p \in P$.

(v) Let us now introduce a relation of the form $\vdash \subseteq \mathcal{P}(M) \times M$ called the relation of R-**linear dependence**. For any subset $X \subseteq M$ and any element $x \in M$ let us define

$$X \vdash x \quad :\Longleftrightarrow \quad \begin{array}{l} \exists\, n \in \mathbb{N}, \exists\, x_1, \ldots, x_n \in X, \exists\, a_1, \ldots, a_n \in R \\ \text{such that } x = a_1 x_1 + \cdots + a_n x_n \end{array}$$

Nota that we allowed $n = 0$ in this definition. And by convention the empty sum is set to be 0. Thus we get $X \vdash 0$ for any subset $X \subseteq M$. In fact we even get $\emptyset \vdash x \iff x = 0$ for any $x \in M$.

(vi) A subset $X \subseteq M$ is said to be R-**linearly dependent** iff for any $1 \leq n \in \mathbb{N}$, any $\{ x_1, \ldots, x_n \} \subseteq X$ and any $a_1, \ldots, a_n \in R$ we get

$$\left.\begin{array}{l} a_1 x_1 + \cdots + a_n x_n = 0 \\ \forall\, i, j \in 1 \ldots n : x_i = x_j \implies i = j \end{array}\right\} \implies \quad a_1 = \cdots = a_n = 0$$

If this is not the case (i.e. there are some $a_1, \ldots, a_n \in R \setminus \{0\}$ and pairwise distinct $x_1, \ldots, x_n \in X$ such that $a_1 x_1 + \cdots + a_n x_n = 0$), then X is said to be R-**linearly dependent**. Finally X is said to be a **maximal** R-linearly independent set, iff X is R-linearly dependent, but any proper superset of X is R-linearly dependent. Formally

$$\forall\, Y \subseteq M \;:\; X \subset Y \implies Y \text{ is } R\text{-linearly dependent}$$

(vii) A subset $B \subseteq M$ is said to be a R-**basis** of M, iff it is R-linearly independent (that is (vi)) and R-generates M (that is (i)). And M is said to be **free**, iff it has a basis. That is

$$M \text{ free} \quad \Longleftrightarrow \quad \exists\, B \subseteq M \;:\; B \text{ is a } R\text{-basis}$$

(viii) Finally an ordered tupel $(x_i) \subseteq M$ (where $i \in I$) is said to be an **ordered** R-**basis** of M, iff it satisfies the following two properties

(1) $\{ x_i \mid i \in I \}$ is a R-basis of M

(2) $\forall\, i, j \in I \;:\; x_i = x_j \implies i = j$

(3.60) Example: (viz. 870)

(i) A very special case in the above definitions is the zero-module $0 = \{0\}$. It is a free module, as $\emptyset \subseteq \{0\}$ is an R-basis of 0. And thereby for an arbitrary R-module M we obtain

$$\mathrm{rank}(M) = 0 \quad \Longleftrightarrow \quad M = \{0\}$$

(ii) From the above definitions it is clear, that M is finitely generated, if and only if the zero-sub-module $0 \leq_{\mathfrak{m}} M$ is cofinite (in M). Also, if P and $Q \leq_{\mathfrak{m}} M$ are sub-modules of M such that P is cofinite and $P \subseteq Q$, then Q is cofinite as well.

(iii) Consider an integral domain $(R, +, \cdot)$ and an R-sub-module (that is an ideal) $\mathfrak{a} \leq_{\mathfrak{m}} R$. Then $\mathfrak{a}$ is a free R-module, if and only if it is a principal ideal

$$\mathfrak{a} \text{ free} \quad \Longleftrightarrow \quad \exists\, a \in R \,:\, \mathfrak{a} = aR$$

(iv) The standard example of a free module is the following: Let $(R, +, \cdot)$ be an arbitrary ring and $I \neq \emptyset$ be any non-empty set. Then we consider

$$R^{\oplus I} \;=\; \bigoplus_{i \in I} R \;=\; \left\{ (x_i) \in R^I \;\middle|\; \#\{\, i \in I \mid x_i \neq 0 \,\} < \infty \right\}$$

Recall that this is an R-module under the component-wise operations $(x_i) + (y_i) := (x_i + y_i)$ and $a(x_i) := (ax_i)$ - where a, a_i and $y_i \in R$. For any $j \in I$ let us denote the **j-th Euclidean vector**

$$e_j \;:=\; (\delta_{i,j}) \;\in\; R^{\oplus I}$$

That is e_j contains 1 exactly once, at the j-th position; all other entries are 0. In other words still: The i-th component of e_j is 1 if and only if $i = j$ and 0 otherwise. Then $R^{\oplus I}$ is a free R-module having the so called **Euclidean basis**

$$\mathcal{E} \;=\; \{\, e_j \mid j \in I \,\}$$

($\diamondsuit$) In particular, if R is a commutative ring, or skew-field, we find that for any set $I \neq \emptyset$ the R-module $R^{\oplus I}$ is free and has dimension $|I|$, as $\mathcal{E}$ is an R-basis of $R^{\oplus I}$

$$\dim\left(R^{\oplus I}\right) \;=\; |I|$$

(3.61) Proposition: (viz. 871)
Let $(R, +, \cdot)$ be an arbitrary ring and M be an R-module. Let us denote the relation of R-linear dependence by $\vdash$ again (refer to (3.59.(iv)). Then the following statements hold true

(i) The relation $\vdash$ of R-linear dependence satisfies the properties (D1), (D2) and (D3) of a dependence relation (refer to (3.55) for the explicit definitions), but not necessarily (D4).

(ii) Recall that for a subset $X \subseteq M$ we defined $\langle X \rangle = \{\, y \in M \mid X \vdash y \,\}$, then we obtain the identities

$$\langle X \rangle \;=\; \langle X \rangle_{\mathfrak{m}} \;=\; \mathrm{Lh}_R(X)$$

(iii) For any subset $X \subseteq M$ the following three statements are equivalent

(a) X is $\vdash$dependent

(b) $\forall\, Y \subseteq M : X \subseteq Y \implies Y$ is $\vdash$dependent

(c) $\exists\, X_0 \subseteq X$ such that $\#X_0 < \infty$ and X_0 is $\vdash$dependent

(iv) For any subset $Y \subseteq M$ the following three statements are equivalent

(a) Y is $\vdash$independent

(b) $\forall\, X \subseteq M : X \subseteq Y \implies X$ is $\vdash$independent

(c) $\forall\, Y_0 \subseteq Y$ we get $\#Y_0 < \infty \implies Y_0$ is $\vdash$independent

(v) A subset $B \subseteq M$ is a $\vdash$basis of M if and only if it is a minimal $\vdash$generating subset of M. Formally that is the equivalence of the following two statements

(a) B is a $\vdash$basis of M

(b) $M = \langle B \rangle$ and $S \subset B \implies M \neq \langle S \rangle$

(vi) A subset $B \subseteq M$ is an R-basis of M if and only if any $x \in M$ has a unique representation as an R-linear combination over B. Formally that is the equivalence of the following two statements

(a) B is an R-basis of M

(b) for any element $x \in M$ there is a uniquely determined tupel $(x_b) \in R^{\oplus B}$ such that x can be represented as a linear combination over the $b \in B$, that is

$$x \;=\; \sum_{b \in B} x_b b$$

Nota that the sum occurring in (b) is well-defined, as only finitely many of the x_b are non-zero. Further note that in fact the existence of such a representation is equivalent to $M = \langle B \rangle_{\mathsf{m}}$ and the uniqueness of the representation is equivalent to the R-linear independence of B.

(3.62) Proposition: (viz. 873)
Let $(R, +, \cdot)$ be any ring and M be an R-module with basis $B \subseteq M$. Consider some subset $A \subseteq B$ and let $P := \mathrm{Lh}_R(A)$ be the sub-module of M generated by A only. Then we obtain the following statements

(i) The quotient module M/P is a free module again, we can explicitly a basis of M/P to be the following set: $\{\, b + P \mid b \in B \setminus A \,\}$ is a basis of M/P.

(ii) *Basis Exchange Theorem*: If $A' \subseteq M$ is another set, such that (1) A' is linearly independent and (2) $\mathrm{Lh}_R(A') = P$ generates the same sub-module, as A, then we find another basis of M by

$$\big(B \setminus A\big) \cup A' \;\text{ is a basis of } M$$

(3.63) Proposition: (viz. 874)
Let $(R, +, \cdot)$ be an integral domain and denote $E := \mathrm{QUOT}(R)$ its quotient field. Also let $I \neq \emptyset$ be any non-empty set and $X \subseteq R^{\oplus I}$. Now the embedding $R \hookrightarrow E : a \mapsto a/1$ gives rise to an embedding $R^{\oplus I} \hookrightarrow E^{\oplus I}$ canonically. In this sense we consider $X \subseteq E^{\oplus I}$, as well. Then the following two statements are equivalent

(a) $X \subseteq R^{\oplus I}$ is R-linearly independent

(b) $X \subseteq E^{\oplus I}$ is E-linearly independent

(3.64) Proposition: (viz. 872)
Let $(S, +, \cdot)$ be a skew-field and M be an S-module. Let us denote the relation of S-linear dependence by $\vdash$ again (refer to (3.59.(iv))). Then we obtain the following statements, in addition to (3.61)

(i) The relation $\vdash$ of S-linear dependence satisfies properties (D1) to (D4) and thereby is a dependence relation [refer to (3.55) for the explicit definitions]. In fact $\vdash$ satisfies the following, slightly stronger property (for any $X \subseteq M$ and any $x, y \in M$)

$$X \vdash y,\ x \in X,\ y \neq 0 \quad \Longrightarrow \quad \Big((X \setminus \{ x \}) \cup \{ y \} \Big) \vdash x$$

(ii) Let $X \subseteq M$ be an arbitrary subset, then the following two statements are equivalent (for arbitrary rings we only get (b) $\Longrightarrow$ (a) here)

(a) X is $\vdash$independent

(b) X is S-linearly independent

(iii) For any $X \subseteq M$ and $y \in M$ the following statements are equivalent

(a) $X \cup \{ y \}$ is S-linearly independent and $y \notin X$

(b) X is S-linearly independent and $X \nvdash y$

(iv) For any subset $B \subseteq M$ all of the following statements are equivalent

(a) B is a $\vdash$basis of M

(b) B is an S-basis of M

(c) B is a minimal S-generating subset of M, that is B generates M [i.e. $M = \mathrm{Lh}_S(B)$], but any proper subset $X \subset B$ does not suffice to generate M

$$X \subset B \quad \Longrightarrow \quad M \neq \mathrm{Lh}_S(X)$$

(d) B is a maximal S-linearly independent subset, that is B is S-linearly independent and any subset $X \subseteq M$ strictly containing B no longer is S-linearly independent

$$B \subset X \quad \Longrightarrow \quad X \text{ is not } S\text{-linearly independent}$$

(e) Any element $x \in M$ can be represented as a uniquely determined linear combination over the elements of B. That is for any $x \in M$, there is a uniquely determined $(x_b) \in S^{\oplus B}$ such that

$$x \;=\; \sum_{b \in B} x_b b$$

(v) Let $X \subseteq M$ be a S-linearly independent subset and $Y \subseteq M$ be a generating subset $M = \mathrm{Lh}_S(Y)$. If now $X \subseteq Y$, then there is some $B \subseteq M$ such that

(1) $X \subseteq B \subseteq Y$ and

(2) B is an S-basis of M

(vi) All S-bases of M have the same number of elements, formally that is

$$A, B \subseteq M \; S\text{-bases of } M \quad \Longrightarrow \quad |A| = |B|$$

(3.65) Remark:
By (3.64.(iv)) S-linear dependence is a dependence relation and the notions of *bases* are the same. But due to (3.58) M then already has a basis B or, in other words, M is a free module. That is we have arrived at a crucial, much celebrated result:

Any module M over a skew-field S already is free!

Now by (3.64.(vi)) all S-bases of M share the same cardinality. Hence we may define the **dimension** of M over S to be the cardinality of *any* S-basis of M. That is we let

$$\dim_S(M) \;:=\; |B| \quad \text{where} \quad B \text{ is an } S\text{-base of } M$$

(3.66) Proposition: (viz. 872)
Let $(S, +, \cdot)$ be a skew-field and M be an S-module. Let us denote the relation of S-linear dependence by $\vdash$ again (refer to (3.59.(iv))). Then we obtain the following statements in addition to (3.61) and (3.64)

(vii) A set of S-linearly elements contains at most $\dim_S(M)$ many elements

$$X \subseteq M \text{ is } S\text{-linearly independent} \quad \Longrightarrow \quad |X| \leq \dim_S(M)$$

(viii) Suppose M is finite-dimensional (i.e. $\dim_S(M) < \infty$) and consider an S-linearly independent subset $X \subseteq M$. Then the following two statements are equivalent

(a) $|X| = \dim_S(M)$

(b) X is an S-basis of M

(ix) Im particular if M is finite-dimensional and $P \leq_{\mathrm{m}} M$ is a sub-module of $\dim(P) = \dim(M) < \infty$ equal dimension, then they already are equal $P = M$, themselves.

(3.67) Remark: (viz. 875)
Let us summarize a bit: If $(R,+,\cdot)$ is a ring, M is an R-module and $\mathcal{M} \subseteq M$ is a subset of M. Let us denote the set of functions from $\mathcal{M}$ to R that are non-zero for finitely many $m \in \mathcal{M}$ only, by

$$\mathcal{F}_0(\mathcal{M},R) \;:=\; \{\, a : \mathcal{M} \to R \;\mid\; \#\{\, m \in \mathcal{M} \mid a(m) \neq 0 \,\} \,\}$$

It is clear, that any $a \in \mathcal{F}_0(\mathcal{M},R)$ corresponds to an R-linear combination of the elements of $\mathcal{M}$. That is the following map is well defined

$$\varrho \;:\; \mathcal{F}_0(\mathcal{M},R) \;\to\; M \;:\; a \;\mapsto\; \sum_{m\in\mathcal{M}} a(m)m$$

The image of ϱ is precisely the R-linear hull of $\mathcal{M}$. And from the construction it is clear that we have the following list of equivalences concerning ϱ and M

$$\begin{aligned} \varrho \text{ is injective} &\iff \mathcal{M} \text{ is linearly independent} \\ \varrho \text{ is surjective} &\iff \mathcal{M} \text{ generates } M \\ \varrho \text{ is bijective} &\iff \mathcal{M} \text{ is a basis of } M \end{aligned}$$

If both $\mathcal{M}$ and R are finite, then $\mathcal{F}_0(\mathcal{M},R) = \mathcal{F}(\mathcal{M},R)$ is finite as well, having $(\#R)^{\#\mathcal{M}}$ elements. If $\mathcal{M}$ or R is infinite then the weird rules of cardinal arithmetic set in: In this case, if M is a free R-module, then the cardinality of M is the maximum of the cardinalities of M and one of its bases $\mathcal{M}$

$$|M| \;=\; \max\{\, |R|, \dim(M) \,\}$$

(3.68) Lemma: (viz. 875)
Let $(S,+,\cdot)$ be a skew-field and consider two S-modules V and W. Then we obtain the following formulae concerning their dimensions

(i) If P and $Q \leq_{\mathsf{m}} V$ are any two S-sub-modules of V, then the dimension of the sum $P+Q$ satisfies the following relation

$$\dim(P+Q) \;=\; \dim(P) + \dim(Q) - \dim(P\cap Q)$$

(ii) If $P \leq_{\mathsf{m}} V$ is an S-sub-module of V then the dimension of the quotient is just the difference of the dimensions of V and P

$$\dim\left(V \,\middle/\, P\right) \;=\; \dim(V) - \dim(P)$$

(iii) If $\varphi : V \to W$ is any S-linear map, then we obtain the following *dimension formula* for the dimension of the kernel and image of φ

$$\dim(V) \;=\; \dim\big(\mathrm{kn}(\varphi)\big) + \dim\big(\mathrm{im}(\varphi)\big)$$

3.8 Homomorphisms

Homomorphism of modules - better known as linear maps - are one of the most common concepts of algebra. Examples are abundant: Derivation and integration of functions, both are linear, the arithmetical mean is linear, matrices are just another way to define linear maps, etc. The advantage of linear maps is, that they are both, well-understood and well-behaved. In fact this concept is so successful, that many theories (e.g. chaos theory) thrive on finding linear approximations for non-linear problems.

(3.69) Definition:

(i) Let $(R,+,\cdot)$ be any ring and consider two R-modules M and N. Then a map $\varphi : M \to N$ is said to be an R-**module-homomorphism** or simply an R-**linear** map, iff for any $a \in R$, x, $y \in M$ we get

$$\begin{aligned} \varphi(ax) &= a\varphi(x) \\ \varphi(x+y) &= \varphi(x)+\varphi(y) \end{aligned}$$

We will denote the set of all R-module-homomorphisms from M to N by $\mathrm{mhom}(M,N)$ or, in order to emphasize the base ring R, by $\mathrm{mhom}_R(M,N)$. In linear algebra (i.e. primarily in case of a base field R) it is also customary to simply write $\mathcal{L}(M,N)$:

$$\mathcal{L}(M,N) \;:=\; \{\, \varphi : M \to N \mid \varphi \text{ is an } R\text{-module-homomorphism} \,\}$$

$$\mathrm{mhom}(M,N) \;:=\; \mathrm{mhom}_R(M,N) \;:=\; \mathcal{L}(M,N)$$

(ii) Consider any two rings $(R,+,\cdot)$ and $(S,+,\cdot)$ and fix a homomorphism of rings $\alpha : R \to S$. Then a map $\varphi : M \to N$ is said to be an α-**module-homomorphism** or simply an α-**linear** map, iff for any $a \in R$ and any x, $y \in M$ we get

$$\begin{aligned} \varphi(ax) &= \alpha(a)\varphi(x) \\ \varphi(x+y) &= \varphi(x)+\varphi(y) \end{aligned}$$

We will denote the set of all R-module-homomorphisms from M to N by $\mathrm{mhom}_\alpha(M,N)$ or, in case α is understood, simply by $\mathrm{mhom}(M,N)$. In linear algebra (i.e. primarily in case of a base field R) it is also customary to write $\mathcal{L}_\alpha(M,N)$:

$$\mathcal{L}_\alpha(M,N) \;:=\; \{\, \varphi : M \to N \mid \varphi \text{ is an } \alpha\text{-module-homomorphism} \,\}$$

$$\mathrm{mhom}(M,N) \;:=\; \mathrm{mhom}_\alpha(M,N) \;:=\; \mathcal{L}_\alpha(M,N)$$

(iii) In any case (i) and (ii) we define the **kernel** $\mathrm{kn}(\varphi)$ and the **image** $\mathrm{im}(\varphi)$ of the map $\varphi : M \to N$ to be the following subsets of M or N respectively

$$\begin{aligned} \mathrm{kn}(\varphi) &:= \{\, x \in M \mid \varphi(x) = 0 \,\} &&\subseteq M \\ \mathrm{im}(\varphi) &:= \{\, \varphi(x) \mid x \in M \,\} &&\subseteq N \end{aligned}$$

And we establish the usual nomenclature: φ is said to be a **mono- epi-** or **isomorphism**, iff it is a homomorphism, that also is injective, surjective or bijective respectively:

φ is called	iff φ is
monomorphism	injective
epimorphism	surjective
isomorphism	bijective

(iv) In case (i), an R-module-homomorphism $\varphi : M \to M$ acting solely on the R-module M is called an R-**module-endomorphism**. And it is called an R-**module-automorphism**, iff it also is bijective

φ is called	iff φ is
endomorphism	$M = N$
automorphism	$M = N$ and bijective

(v) If M and N are any two R-modules, then M and N are said to be **isomorphic**, iff there is an isomorphism of R-modules from M to N, formally we write

$$M \cong_{\mathsf{m}} N \quad :\Longleftrightarrow \quad \exists\, \Phi : M \to N \;\; R\text{-module isomorphism}$$

(3.70) Example:

(i) The most easy and completely trivial example is the *zero-homomorphism*. If M and N are any two R-modules, then we obtain an R-module-homomorphism 0 by letting

$$0 \;:\; M \to N \;:\; x \mapsto 0$$

(ii) Another trivial example of an R-module-homomorphism is the *identity map* $\mathbb{1}$ on some R-module M, that simply returns the element x it was given

$$\mathbb{1} \;:\; M \to M \;:\; x \mapsto x$$

(iii) A slight generalization is the map of set theoretical inclusion, which (by abuse of notation) is written as $\subseteq$ again. If $P \leq_{\mathsf{m}} M$ is a sub-module of the R-module M, then we get an R-module-homomorphism by

$$\subseteq \;:\; P \to M \;:\; x \mapsto x$$

(iv) Regard $M := R[t]$ the polynomial ring over R, as an R-module. Then for any $f \in R[t]$ we define the *derivation* of f to be the following polynomial again

$$\partial f(t) \;:=\; \sum_{k=1}^{\infty} k f[k]\, t^{k-1} \;\in\; R[t]$$

And thereby $\partial : R[t] \to R[t]$ is a homomorphism of R-modules, with $\mathrm{im}(\partial) \subseteq R[t]$ and $R \subseteq \mathrm{kn}(\partial)$. In fact we will study such maps more closely in section 7.6 and see, that ∂ is no homomorphism of rings, as it satisfies the property $\partial(f \cdot g) = (\partial f) \cdot g + f \cdot (\partial g)$ for any $f, g \in R$.

(3.71) Remark: (viz. 766)

(i) The notion (ii) of α-linearity clearly includes the case (i) of R-linearity - just take $\alpha = \mathbb{1} : R \to R$, then an α-linear map $\varphi : M \to N$ is nothing but an R-linear map.

(ii) If $\varphi : M \to N$ is an R-module-homomorphism, then the kernel and image of φ are sub-modules of M and N respectively:

$$\begin{aligned} \mathrm{kn}(\varphi) &= \{\, x \in M \mid \varphi(x) = 0 \,\} &\leq_{\mathfrak{m}}\ M \\ \mathrm{im}(\varphi) &= \{\, \varphi(x) \mid x \in M \,\} &\leq_{\mathfrak{m}}\ N \end{aligned}$$

More generally: If $\varphi : M \to N$ is an α-module-homomorphism then $\mathrm{kn}(\varphi)$ is an R-sub-module of M. And if α is surjective, then $\mathrm{im}(\varphi)$ also is an S-sub-module of N.

(iii) If $\varphi : M \to N$ is an R-module-homomorphism, then φ is surjective iff its image is N and φ is injective iff its kernel is 0, formally these are the equivalences

$$\begin{aligned} \varphi \text{ is surjective} &\iff \mathrm{im}(\varphi) = N \\ \varphi \text{ is injective} &\iff \mathrm{kn}(\varphi) = \{0\} \end{aligned}$$

(iv) If R is any ring and M and N are any R-modules, also $P \leq_{\mathfrak{m}} M$ and $Q \leq_{\mathfrak{m}} N$ are sub-modules of M and N respectively and $\varphi : M \to N$ is an R-module-homomorphism, then $\varphi(P) \leq_{\mathfrak{m}} N$ and $\varphi^{-1}(Q) \leq_{\mathfrak{m}} M$ are sub-modules of N and M again:

$$\begin{aligned} \varphi(P) &= \{\, \varphi(x) \mid x \in P \,\} &\leq_{\mathfrak{m}}\ N \\ \varphi^{-1}(Q) &= \{\, x \in M \mid \varphi(x) \in Q \,\} &\leq_{\mathfrak{m}}\ M \end{aligned}$$

More generally: If $\varphi : M \to N$ is an α-module-homomorphism then $\varphi^{-1}(Q)$ is an R-sub-module of M. And if α is surjective, then $\varphi(P)$ also is an S-sub-module of N.

(v) If L, M and N all are R-modules and the maps $\varphi : L \to M$ and $\psi : M \to N$ both are homomorphisms of R-modules then the composition $\psi\varphi$ is a homomorphism of R-modules as well

$$\psi\varphi \ :\ L \to N \ :\ x \mapsto \psi(\varphi(x))$$

More generally: Suppose L is an R-module, M is an S-module and N is an T-module, where $(R, +, \cdot)$, $(S, +, \cdot)$ and $(T, +, \cdot)$ are arbitrary rings. Further we fix ring homomorphisms $\alpha : R \to S$ and $\beta : S \to T$. If now $\varphi : L \to M$ is an α-module-homomorphism and $\psi : M \to N$ is an β-module-homomorphism, then the composition $\psi\varphi : L \to N$ is an $(\beta\alpha)$-module-homomorphism.

(vi) If M and N are R-modules, where $(R,+,\cdot)$ is a commutative ring, then the set $\mathrm{mhom}_R(M,N)$ of all R-module-homomorphisms from M to N becomes an R-module in itself. Thereby for any φ, $\psi \in \mathrm{mhom}_R(M,N)$ and any $a \in R$ we take the following operations

$$\begin{aligned} \varphi+\psi &: M \to N : \quad x \mapsto \varphi(x)+\psi(x) \\ a\varphi &: M \to N : \quad x \mapsto a\varphi(x) \end{aligned}$$

(vii) More generally: Suppose $(R,+,\cdot)$ is an arbitrary and $(S,+,\cdot)$ is a commutative ring, M is an R-module and N is an S-module. Further fix a homomorphism $\alpha : R \to S$ of rings. Then $\mathrm{mhom}_\alpha(M,N)$ becomes an S-module under the above operations of (vi).

(viii) If $(R,+,\cdot)$ is a commutative ring and M is an R-module, then the set $\mathrm{end}(M) = \mathrm{mhom}(M,M)$ of module R-homomorphisms $\varphi : M \to M$ from M to itself is a commutative ring $(\mathrm{end}(M),+,\circ)$ under the point-wise addition $\varphi+\psi : x \mapsto \varphi(x)+\psi(x)$ and composition $\circ$ of maps $\varphi\psi : x \mapsto \varphi(\psi(x))$. The unit element of $\mathrm{end}(M)$ is the identity map $\mathbb{1}_M : x \mapsto x$.

(ix) If $(R,+,\cdot)$ is any ring, M is an R-module, $P \leq_{\mathsf{m}} M$ is a sub-module of M and $\Phi \in \mathrm{maut}(M)$ an automorphism of M, then we obtain the following isomorphy of R-modules

$$M\big/_P \xrightarrow{\sim} M\big/_{\Phi(P)} \; : \; x+P \mapsto \Phi(x)+\Phi(P)$$

(x) Consider any non-empty subset $X \subseteq M$, $X \neq \emptyset$ of M. Then we examine the R-module-homomorphism that takes tuples (a_x) to linear combinations over the elements of X

$$\varrho \; : \; R^{\oplus X} \to M \; : \; (a_x) \mapsto \sum_{x \in X} a_x x$$

Note that ϱ is well-defined, as in any $(a_x) \in R^{\oplus X}$ only finitely many a_x are non-zero. Also - as the compositions on $R^{\oplus X}$ are component-wise - it is clear, that ϱ truly is a homomorphism of R-modules. Yet ϱ also satisfies a number of interesting properties

$$\begin{aligned} \mathrm{im}(\varrho) &= \mathrm{Lh}_R(X) \\ \varrho \text{ is surjective} &\iff X \text{ generates } M \\ \varrho \text{ is injective} &\iff X \text{ is } R\text{-linearly independent} \\ \varrho \text{ is bijective} &\iff X \text{ is an } R\text{-basis of } M \end{aligned}$$

In particular, iff $B \subseteq M$ is a basis, then ϱ is an isomorphy of R-modules $\varrho : R^{\oplus B} \xrightarrow{\sim} M$. That is all free R-modules are of the form $R^{\oplus B}$ for some set B.

(3.72) Proposition: (viz. 768)
Let $(R,+,\cdot)$ be an arbitrary ring and consider any two R-modules M and N. Then we find the statements:

(i) If $X \subseteq M$ generates M, that is $M = \ln(X)$, and $\varphi, \psi : M \to N$ are any two R-linear maps, then the equality of φ and ψ is determined on X. That is the equivalency of

$$\varphi\big|_X \;=\; \psi\big|_X \quad\Longleftrightarrow\quad \varphi \;=\; \psi$$

(ii) And if $B \subseteq M$ even is an R-basis of M and $n : B \to N$ is an arbitrary map from B to N, then there is a uniquely defined R-linear map $\varphi : M \to N$ satisfying $\varphi\big|_B = n$. (It is customary to say that φ is generated by *linear expansion* of the map n). And this is given to be

$$\varphi\left(\sum_{x\in B} a_x x\right) \;:=\; \sum_{x\in B} a_x n(x)$$

(3.73) Definition: (viz. 769)

(i) Fix a commutative ring $(R,+,\cdot)$ and consider the three R-modules L, M and N. If $\psi : M \to N$ is an R-module-homomorphism, then ψ induces another R-module-homomorphism ψ_* called the **push-forward** of ψ by letting

$$\psi_* \;:\; \mathrm{mhom}_R(L,M) \to \mathrm{mhom}_R(L,N) \;:\; \varphi \mapsto \psi\varphi$$

(ii) Fix a commutative ring $(R,+,\cdot)$ and consider the three R-modules L, M and N. If $\varphi : L \to M$ is an R-module-homomorphism, then φ induces another R-module-morphism φ^* called the **pull-back** of φ by letting

$$\varphi^* \;:\; \mathrm{mhom}_R(N,M) \to \mathrm{mhom}_R(L,N) \;:\; \psi \mapsto \psi\varphi$$

(iii) More generally: Suppose L is an R-module, M is an S-module and N is a T-module, where $(R,+,\cdot)$ is an arbitrary, $(S,+,\cdot)$ and $(T,+,\cdot)$ are commutative rings. Further we fix ring homomorphisms $\alpha : R \to S$ and $\beta : S \to T$. If now $\psi : M \to N$ is an β-module-homomorphism, then ψ induces another $\beta\alpha$-module-homomorphism ψ_* called the **push-forward** of ψ by letting

$$\psi_* \;:\; \mathrm{mhom}_\alpha(L,M) \to \mathrm{mhom}_{\beta\alpha}(L,N) \;:\; \varphi \mapsto \psi\varphi$$

(iv) Suppose L is an R-module, M is an S-module and N is a T-module, where $(R,+,\cdot)$ is an arbitrary, $(S,+,\cdot)$ and $(T,+,\cdot)$ are commutative rings. Further we fix ring homomorphisms $\alpha : R \to S$ and $\beta : S \to T$. If now $\psi : M \to N$ is an β-module-homomorphism, then φ induces another $\beta\alpha$-module-homomorphism φ^* called the **bf pull-back** of φ by letting

$$\varphi^* \;:\; \mathrm{mhom}_\beta(M,N) \to \mathrm{mhom}_{\beta\alpha}(L,N) \;:\; \psi \mapsto \psi\varphi$$

(3.74) Proposition: (viz. 769)
Let M be an R-module over an arbitrary ring $(R,+,\cdot)$ and consider $\pi : M \to M$ an R-module-endomorphism. We say that π is a *projection* if $\pi^2 = \pi$ and in this case the image of π is given to be $\mathrm{im}(\pi) = \{\, x \in M \mid \pi(x) = x \,\}$ and thereby M is the inner direct product of

$$M \;=\; \mathrm{im}(\pi) \oplus \mathrm{kn}(\pi)$$

We have introduced *linear* maps, that is homomorphisms of modules. And we have also introduced products of modules. Sometimes we will want to consider maps on products of modules, that respect the module structure on every single module. These maps will be called *multilinear*, but as the general definition might be somewhat irritating, let us regard the easiest yet most important case beforehand:
Let $(R,+,\cdot)$ be a ring and consider three R-modules M_1, M_2 and N. Then a map $\varphi : M_1 \times M_2 \to N$ is said to be **bilinear** (sometimes they are called *balanced* instead) if for any $a \in R$, any $x_1, y_1 \in M_1$ and any $x_2, y_2 \in M$ it satisfies the following four properties:

$$\begin{aligned}
\varphi(ax_1, x_2) &= a\,\varphi(x_1, x_2) \\
\varphi(x_1 + y_1, x_2) &= \varphi(x_1, x_2) + \varphi(y_1, x_2) \\
\varphi(x_1, ax_2) &= a\,\varphi(x_1, x_2) \\
\varphi(x_1, x_2 + y_2) &= \varphi(x_1, x_2) + \varphi(x_1, y_2)
\end{aligned}$$

In other words φ is *linear in the first argument* [i.e. for any $x_2 \in M_2$ the map $M_1 \to N : x_1 \mapsto \varphi(x_1, x_2)$ is a homomorphism of R-modules] and *linear in the second argument* [i.e. for any $x_1 \in M_1$ the map $M_2 \to N : x_1 \mapsto \varphi(x_1, x_2)$ is a homomorphism of R-modules]. This clearly can be generalized to arbitrarily numerous products of modules: What we require of a *multilinear* map is, that is linear in every single of its arguments. This is the easy idea behind the following (a little hard to read) definition. In this sense a bilinear map is nothing more than a multilinear map, where the index is $I = \{\, 1, 2 \,\}$.

(3.75) Definition:
Let $(R,+,\cdot)$ be any ring and consider a family (M_i) (where $i \in I$ and $I \neq \emptyset$) of R-modules. Let finally M be a sub-module of the exterior direct product

$$M \;\leq_{\mathrm{m}}\; \prod_{i \in I} M_i$$

(i) Let N be another R-module, then a map $\varphi : M \to N$ is said to be **R-multilinear**, iff for any $i \in I$ and any fixed $(x_j)_{j \neq i}$ [where $x_j \in M_j$ for $i \neq j \in I$] the map $M_i \to N : x_i \mapsto \varphi(x)$ [where $x = (x_j)_{j \in I}$] is R-linear. That is for any $i \in I$ let us abbreviate arbitrary elements of the M_j for $j \neq i$ by dots, then for any $a \in R$ and any $x_i, y_i \in M_i$ we require φ to satisfy

$$\begin{aligned}
\varphi(\ldots, ax_i, \ldots) &= a\varphi(\ldots, x_i, \ldots) \\
\varphi(\ldots, x_i + y_i, \ldots) &= \varphi(\ldots, x_i, \ldots) + \varphi(\ldots, y_i, \ldots)
\end{aligned}$$

(ii) Let $(S,+,\cdot)$ be another ring, let N be an S-module and fix a ring-homomorphism $\alpha : R \to S$. Then a map $\varphi : M \to N$ is said to be **α-multilinear**, iff for any $i \in I$ and any fixed $(x_j)_{j\neq i}$ [where $x_j \in M_j$ for $i \neq j \in I$] the map $M_i \to N : x_i \mapsto \varphi(x)$ [where $x = (x_j)_{j\in I}$] is α-linear. That is for any $i \in I$ let us abbreviate arbitrary elements of the M_j for $j \neq i$ by dots, then for any $a \in R$ and any x_i, $y_i \in M_i$ we require φ to satisfy

$$\begin{aligned} \varphi(\dots, ax_i, \dots) &= \alpha(a)\varphi(\dots, x_i, \dots) \\ \varphi(\dots, x_i + y_i, \dots) &= \varphi(\dots, x_i, \dots) + \varphi(\dots, y_i, \dots) \end{aligned}$$

(3.76) Example: (viz. 769)
Let $(R,+,\cdot)$ be any ring, then we can simultaneously regard $R^2 = R \oplus R$ as an R-module or as a product of two R-modules R. In particular we can consider both R-linear and R-bilinear maps:

(i) The addition map $\alpha : R^2 \to R : (a,b) \mapsto a+b$ on R is R-linear but *not* necessarily R-bilinear.

(ii) The multiplication map $\mu : R^2 \to R : (a,b) \mapsto ab$ is R-bilinear but *not* necessarily R-linear.

(iii) The canonical projections $\pi_1 : R^2 \to R : (a,b) \mapsto a$ and $\pi_2 : R^2 \to R : (a,b) \mapsto b$ are R-linear but *not* necessarily R-bilinear.

(iv) If $(R,+,\cdot)$ is an arbitrary ring and M is an R-module, then the properties of being an R-module precisely state, that the scalar multiplication of M is R-bilinear

$$R \times M \to M \ : \ (a,x) \mapsto ax$$

(v) ($\diamondsuit$) If $(R,+,\cdot)$ is a *commutative* ring and $1 \leq \ell$, m and $n \in \mathbb{N}$ then the multiplication of matrices is R-bilinear, as well. Thereby the multiplication is a map of the following form

$$\mathrm{mat}_{\ell,m}(R) \times \mathrm{mat}_{m,n}(R) \to \mathrm{mat}_{\ell,n}(R) \ : \ (A,B) \mapsto AB$$

(vi) ($\diamondsuit$) The complex numbers $\mathbb{C}$ have the complex conjugation κ as a field-automorphism which is defined to be $\kappa(x+iy) = x - iy$. This is usually denoted by $\overline{z} = \kappa(z)$ for $z = x+iy \in \mathbb{C}$. If now U and V are $\mathbb{C}$-vectorspaces, then a map $\varphi : U \times V \to \mathbb{C}$ is said to be *sesqui-linear*, iff it satisfies the following four properties:

$$\begin{aligned} \varphi(au, v) &= a\,\varphi(u,v) \\ \varphi(u+u', v) &= \varphi(u,v) + \varphi(u',v) \\ \varphi(u, av) &= \overline{a}\,\varphi(u,v) \\ \varphi(u, v+v') &= \varphi(u,v) + \varphi(u,v') \end{aligned}$$

for any $a \in \mathbb{C}$, u, $u' \in U$ and v, $v' \in V$. That is φ is $\mathbb{C}$-linear in the first argument, but a κ-homomorphism in the second argument. We will study and use such maps in section 4.7.

3.9 Isomorphism Theorems

In this section we will study several basic properties of homomorphisms of R-modules. First of all we will encounter the fundamental "isomorphism theorems". Later on we will get some more advanced criteria whether an endomorphism is an isomorphism. A more general way to look at homomorphisms is to study chains of homomorphisms. This is the ascent of homological algebra and we will already introduce the fundamental concepts and its first properties here.

(3.77) Proposition: (viz. 770)
Let $(R,+,\cdot)$ be any ring and consider a homomorphism $\Phi : M \to N$ between the R-modules M and N. Then the following statements are equivalent (and in this case we already get $\alpha = \beta = \Psi = \Phi^{-1}$)

(a) Φ is bijective

(b) There is some homomorphism $\Psi : N \to M$ of R-modules, such that $\Psi\Phi = \mathbb{1}_M$ and $\Phi\Psi = \mathbb{1}_N$

(c) There are arbitrary maps $\alpha : N \to M$ and $\beta : N \to M$, such that $\alpha\Phi = \mathbb{1}_M$ and $\Phi\beta = \mathbb{1}_N$

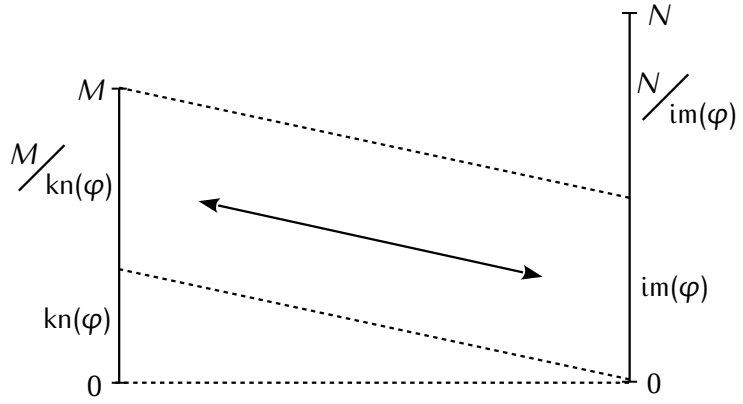
(3.78) Theorem: (viz. 770)
Let $(R,+,\cdot)$ be any ring and consider any two R-modules M and N. Let further $\varphi : M \to N$ be an R-module-homomorphism, then the following statements are true

(i) If $P \leq_{\mathfrak{m}} M$ and $Q \leq_{\mathfrak{m}} N$ are sub-modules of M and N respectively, such that $P \subseteq \varphi^{-1}(Q)$, then we obtain a well-defined homomorphism of R-modules, by letting

$$\overline{\varphi} : M\big/_P \to N\big/_Q : x+P \mapsto \varphi(x)+Q$$

(ii) **1st Isomorphism Theorem:** Any R-module-homomorphism $\varphi : M \to N$ induces an isomorphism of R-modules from the quotient module $M/\mathrm{kn}(\varphi)$ to $\mathrm{im}(\varphi)$ by virtue of

$$\overline{\varphi} : M\big/_{\mathrm{kn}(\varphi)} \xrightarrow{\sim} \mathrm{im}(\varphi) : x+\mathrm{kn}(\varphi) \mapsto \varphi(x)$$



(iii) **2nd Isomorphism Theorem:** If P and $Q \leq_{\mathfrak{m}} M$ are any two sub-modules of M, we obtain another isomorphism of R-modules, by virtue of

$$Q\big/_{P\cap Q} \xrightarrow{\sim} P+Q\big/_P : x+P\cap Q \mapsto x+P$$

(iv) **3rd Isomorphism Theorem:** If P and $Q \leq_{\mathfrak{m}} M$ are sub-modules of M again, such that $P \subseteq Q$, then we obtain one more isomorphism of R-modules, by virtue of

$$M\big/_Q \xrightarrow{\sim} M/P\big/_{Q/P} : x+Q \mapsto (x+P)+Q\big/_P$$

(3.79) Remark:
The following illustration should help to foster an intuitive understanding of what the first isomorphism theorem is all about: We see M on the left-hand side and N on the right hand side. The kernel of φ is the part of M that is mapped to 0 in N. The "rest" $M/\mathrm{kn}(\varphi)$ is copied - without loss of structure or information - to $\mathrm{im}(\varphi)$ which is part of N. The "rest" $N/\mathrm{im}(\varphi)$ of N is of unknown size and structure.

(3.80) Proposition: (viz. 771)
Consider the module M over an arbitrary ring $(R,+,\cdot)$ and let $P \leq_{\mathsf{m}} M$ be a sub-module of M. Then the following statements are equivalent

(a) There is an isomorphism Φ of the form given below, that also satisfies $\Phi(P) = P \oplus 0 = P \times \{\, 0 + P \,\}$

$$\Phi \;:\; M \;\xrightarrow{\sim}\; P \oplus M\big/_P$$

(b) P is a *direct summand* of M, i.e. there is another sub-module $Q \leq_{\mathsf{m}} M$ of M such that $M = P + Q$ and $P \cap Q = 0$, such that M is the inner direct sum

$$M \;=\; P \oplus Q$$

(c) There is a projection $\pi : M \to M$, that is an endomorphism with $\pi^2 = \pi$, such that $\mathrm{im}(\pi) = P$.

(3.81) Remark:
If M is an R-module over some ring $(R,+,\cdot)$ and $P \leq_{\mathsf{m}} M$ is a sub-module such that $M = P \oplus Q$ for some other sub-module $Q \leq_{\mathsf{m}} M$, then the above proposition yields an isomorphism of the form

$$M \;\cong_{\mathsf{m}}\; P \oplus M\big/_P \;:\; p + q \mapsto (p, q + P)$$

However an isomorphism of this form need not exist in general. As a counterexample we consider $M = \mathbb{Z}$ as an $R = \mathbb{Z}$ module with its ideal (i.e. sub-module) $2\mathbb{Z} \leq_{\mathsf{m}} \mathbb{Z}$. The quotient $\mathbb{Z}_2 = \mathbb{Z}/2\mathbb{Z}$ only consists of the elements $\overline{0} = 0 + 2\mathbb{Z}$ and $\overline{1} = 1 + 2\mathbb{Z}$. Suppose there was some isomorphism $\Phi : \mathbb{Z} \xrightarrow{\sim} 2\mathbb{Z} \oplus \mathbb{Z}_2$. We will disprove this by regarding $c := \Phi^{-1}(0,\overline{1}) \in \mathbb{Z}$. Clearly $\Phi(2c) = 2(0,\overline{1}) = (0,\overline{0})$. But as Φ is injective, this means $2c = 0$. Yet $\mathbb{Z}$ has no zero-divisors such that $c = 0$ in contradiction to $\Phi(c) = (0,\overline{1}) \neq 0$.

(3.82) Corollary: (viz. 971)

(i) Consider a commutative ring $(R,+,\cdot)$ and a finitely generated R-module M. If now $\varphi : M \to M$ is an R-module-endomorphism, then the following two statements are equivalent:

(a) φ is surjective

(b) φ is bijective

(ii) Consider a commutative ring $(R,+,\cdot)$ and an artinian R-module M. If now $\varphi : M \to M$ is an R-module-endomorphism, then the following two statements are equivalent:

(a) φ is injective

(b) φ is bijective

(iii) Consider a skew-field $(S,+,\cdot)$ and a finitely generated S-module V. If now $\varphi : V \to V$ is an S-module-endomorphism, then the following three statements are equivalent:

(a) φ is injective

(b) φ is surjective

(c) φ is bijective

(3.83) Lemma: (viz. 994)
Let $(R,+,\cdot)$ be a commutative ring then the following statements are true

(i) If $R \neq 0$ is non-zero and I, $J \neq \emptyset$ are any two non-empty sets, then $R^{\oplus I}$ is isomorphic (as an R-module) to $R^{\oplus J}$ iff I and J have the same cardinality, formally that is

$$R^{\oplus I} \cong_{\mathfrak{m}} R^{\oplus J} \quad \Longleftrightarrow \quad |I| = |J|$$

(ii) Let $\mathfrak{a}$, $\mathfrak{b} \trianglelefteq_{\mathfrak{i}} R$ be two ideals in R, if now $R/\mathfrak{a}$ and $R/\mathfrak{b}$ are isomorphic as R-modules, then $\mathfrak{a}$ and $\mathfrak{b}$ already have to be equal, as subsets of R

$$R\Big/_{\mathfrak{a}} \cong_{\mathfrak{m}} R\Big/_{\mathfrak{b}} \quad \Longleftrightarrow \quad \mathfrak{a} = \mathfrak{b}$$

(3.84) Remark:

- The statement of (i) need not be true for non-commutative rings R. As an example fix the $\mathbb{Z}$-module $M := \mathbb{Z}^{\oplus\mathbb{N}}$ and take to the ring of $\mathbb{Z}$-module endomorphisms of M

 $$S := \operatorname{end}(M)$$

 Then for any $m, n \in \mathbb{N}$ we find that $S^m \cong_{\mathfrak{m}} S^n$ are isomorphic as S-modules. In fact it suffices to give a basis of S consisting of two elements. It is easy to see $M \cong_{\mathfrak{m}} M \oplus M$ and hence

 $$\begin{aligned} S &= \operatorname{mhom}(M,M) \cong_{\mathfrak{m}} \operatorname{mhom}(M, M\oplus M) \\ &\cong_{\mathfrak{m}} \operatorname{mhom}(M,M) \oplus \operatorname{mhom}(M,M) = S^2 \end{aligned}$$

For more details on this construction refer to [Scheja, Storch, Algebra 1, Kapitel 25 Beispiel 3 and Kapitel 36 Beispiel 2], which is the source of this counter-example.

- A ring R with the property of (i) is also called to have IBN (invariant basis number). Thus (i) may be expressed as *commutative rings have IBN*. Of course there is a multitude of non-commutative rings that have IBN, as well. An important example is: If $\varphi : R \twoheadrightarrow S$ is a ring-epimorphism and S has IBN then R has IBN, as well. For more comments on this, please refer to the first chapter of [Lam, A first Course in non-commutative Rings, GTM 131].

- In (ii) it does not suffice to have an isomorphism of R-modules $\mathfrak{a} \cong_{\mathsf{m}} \mathfrak{b}$. E.g. regard the ring $S := R[s,t]$. If we now define the ideals $\mathfrak{a} := tS$ and $\mathfrak{b} := stS$ then $\mathfrak{a}$ and $\mathfrak{b}$ clearly are isomorphic as R-modules, but

$$\begin{array}{lll} S\big/_{\mathfrak{a}} & \cong_{\mathsf{a}} & R[s] \\ S\big/_{\mathfrak{b}} & \cong_{\mathsf{a}} & R[s] \oplus tR[t] \end{array}$$

- In (3.99.(ii)) we will present a much stronger statement: If M is a free R-module, then any R-basis of M has cardinality $\mathsf{rank}(M)$ - supposed R is commutative. And as the isomorphism $R^{\oplus I} \cong_{\mathsf{m}} R^{\oplus J}$ transfers bases we could conclude

$$|I| \;=\; \mathsf{rank}(R^{\oplus I}) \;=\; \mathsf{rank}(R^{\oplus J}) \;=\; |J|$$

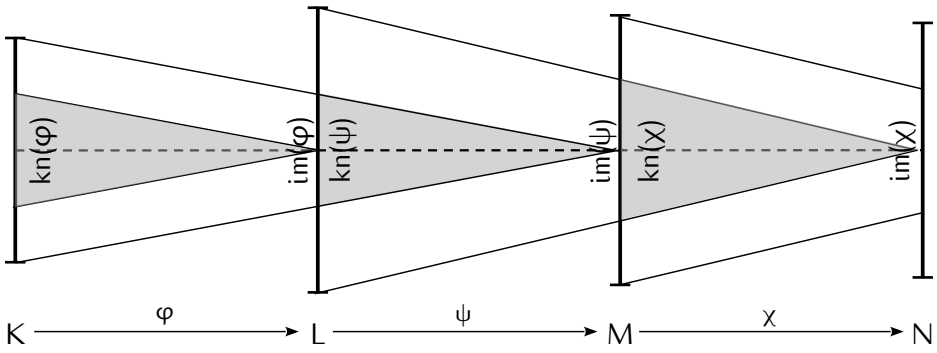
 Yet the proof of this statement is far longer and uses substantially more tools (the theory of noetherian modules), hence we have chosen to give a more direct proof in advance.

(3.85) Definition:
Fix any number $1 \leq n \in \mathbb{N}$ and a ring $(R, +, \cdot)$. Further consider some R-modules M_i (where $i \in 0 \dots n$) and some R-module-homomorphisms, $\varphi_i : M_{i-1} \to M_i$ (where $i \in 1 \dots n$). That is we have

(1) for any $i \in 0 \dots n$: M_i is an R-module

(2) for any $i \in 1 \dots n$: $\varphi_i : M_{i-1} \to M_i$ is an R-module homomorphism

Let us denote $M = (M_i)$ and $\varphi = (\varphi_i)$, then the ordered pair (M, φ) is said to be a **(finite) chain** of R-modules. And in this case we will use a rather intuitive notation for the chain (M, φ), namely



$$M_0 \xrightarrow{\varphi_1} M_1 \xrightarrow{\varphi_2} M_2 \to \cdots \to M_{n-1} \xrightarrow{\varphi_n} M_n$$

And a chain (M, φ) is said to be a **complex** of R-modules, iff we also have the following property (C). Nota an equivalent formulation of (C) is: $\varphi_i \varphi_{i-1} = 0$ for any $i \in 2 \dots n$. And (M, φ) is said to be an **exact chain** of R-modules, iff apart from (1) and (2) it also satisfies the even stronger property (E), where

(C) for any $i \in 2 \dots n$ we have $\mathsf{im}(\varphi_{i-1}) \subseteq \mathsf{kn}(\varphi_i)$

(E) for any $i \in 2 \dots n$ we have $\mathsf{im}(\varphi_{i-1}) = \mathsf{kn}(\varphi_i)$

(3.86) Remark:
The following diagram is supposed to help illustrating the concept of an exact chain in an example featuring 4 modules K, L, M and N. The fact that the image of the previous homomorphism is exactly the kernel of the subsequent homomorphism turns into the condition, that the connecting lines from one module (e.g. from K) to 0 in the over-next module (in M) goes straight and does not leave a gap:

(3.87) Remark:

(i) If $M_i = 0$, then we necessarily have $\varphi_i = 0$ and $\varphi_{i+1} = 0$, that is $\varphi_i : M_{i-1} \to 0 : x_{i-1} \mapsto 0$ and $\varphi_{i+1} : 0 \to M_{i+1} : 0 \mapsto 0$. As these maps are already determined, we don't have to denote them in the chain of modules and may just write

$$M_{i-2} \xrightarrow{\varphi_{i-1}} M_{i-1} \to 0 \to M_{i+1} \xrightarrow{\varphi_{i+2}} M_{i+2}$$

If this chain is exact, then it even follows that $\ker(\varphi_{i+2}) = 0$ and $\operatorname{im}(\varphi_{i-1}) = M_{i-1}$ such that φ_{i+2} is injective and φ_{i-1} is surjective, formally these are the implications

$$\begin{aligned} M_i = 0 \quad &\Longrightarrow \quad \varphi_{i+2} \text{ is injective} \\ M_i = 0 \quad &\Longrightarrow \quad \varphi_{i-1} \text{ is surjective} \end{aligned}$$

Prob due to the exactness of the chain we get $\operatorname{im}(\varphi_{i-1}) = \ker(\varphi_i) = \ker(0) = M_{i-1}$ and hence φ_{i-1} is surjective. Likewise $\ker(\varphi_{i+2}) = \operatorname{im}(\varphi_{i+1}) = \operatorname{im}(0) = 0$ and hence φ_{i+2} is injective.

(ii) In particular for any R-module homomorphism $\varphi : M \to N$ we get a chain of R-modules, by taking

$$0 \to M \xrightarrow{\varphi} N \to 0$$

And this chain is exact if and only if φ is an isomorphism. Prob due to (i) the chain is exact, iff φ is injective and surjective, that is iff φ is bijective. And that's when φ is called an isomorphism.

(iii) In a similar fashion we find a chain-version of the first isomorphism theorem: Given an exact chain (i.e. $\operatorname{im}(\psi) = N$ and $\ker(\psi) = \operatorname{im}(\varphi)$) of R-modules, of the form

$$L \xrightarrow{\varphi} M \xrightarrow{\psi} N \to 0$$

the first isomorphism theorem of R-modules yields the following isomorphism, induced by ψ

$$M\Big/_{\mathrm{im}(\varphi)} \xrightarrow{\sim} N \,:\, x+\mathrm{im}(\varphi) \mapsto \psi(x)$$

(iv) A **short exact sequence** of R-modules is an exact chain of R-modules ($n=5$) of the following form:

$$0 \to L \xrightarrow{\varphi} M \xrightarrow{\psi} N \to 0$$

And as we have seen (iii) this induces an isomorphism $M/\mathrm{im}(\varphi) \xrightarrow{\sim} N$. But as in this case φ also is injective, we have $\varphi : L \xrightarrow{\sim} L' := \mathrm{im}(\varphi)$, that is there is an isomorphic copy $L' \leq_{\mathfrak{m}} M$ of L in M. And for this we get $M/L' \xrightarrow{\sim} N$, according to (iii). This is the essence of what a short exact chain of R-modules is about.

(3.88) Example:

(i) Any sub-module $P \leq_{\mathfrak{m}} M$ gives rise to a canonical short exact sequence, by taking the inclusion $\subseteq : x \mapsto x$ and the canonical projection $\varrho(x) := x + P$

$$0 \to P \xrightarrow{\subseteq} M \xrightarrow{\varrho} M\Big/_P \to 0$$

(ii) Any R-module-homomorphism $\varphi : M \to N$ induces a canonical short exact sequence of R-modules

$$0 \to \mathrm{kn}(\varphi) \xrightarrow{\subseteq} M \xrightarrow{\varphi} \mathrm{im}(\varphi) \to 0$$

(iii) But φ also induces another chain of R-modules: Let us denote $\pi : N \to N/\mathrm{im}(\varphi) : y \mapsto y + \mathrm{im}(\varphi)$ the canonical projection, then we find another exact chain of R-modules, by taking

$$0 \to \mathrm{kn}(\varphi) \xrightarrow{\subseteq} M \xrightarrow{\varphi} N \xrightarrow{\pi} N\Big/_{\mathrm{im}(\varphi)} \to 0$$

(iv) Another, most important example is the following: Consider any two R-modules L and N. Let us denote the canonical embedding of L into $L \oplus N$ by $\iota : L \to L \oplus N : x \mapsto (x,0)$ and the canonical projection onto N by $\pi : L \oplus N \to N : (x,y) \mapsto y$. Then $\mathrm{im}(\iota) = L \oplus 0 = \mathrm{kn}(\pi)$, such that we get the short exact chain of R-modules

$$0 \to L \xrightarrow{\iota} L \oplus N \xrightarrow{\pi} N \to 0$$

(v) Let us alter the above example a little: Given two sub-modules P and $Q \leq_{\mathfrak{m}} M$ of some R-module M, we take the maps $\sigma : P \cap Q \to P \oplus Q : x \mapsto (x,x)$ and $\delta : P \oplus Q \to P + Q : (x,y) \mapsto x - y$. Then we get an exact chain of R-modules

$$0 \to P \cap Q \xrightarrow{\sigma} P \oplus Q \xrightarrow{\delta} P + Q \to 0$$

Passing to quotients we find another exact chain of R-modules: This time the homomorphisms are given to be $\sigma : x \mapsto (x+P, x+Q)$ and $\delta : (x+P, y+Q) \mapsto (x-y) + (P+Q)$

$$0 \to M\big/_{P\cap Q} \xrightarrow{\sigma} M\big/_{P} \oplus M\big/_{Q} \xrightarrow{\delta} M\big/_{P+Q} \to 0$$

We see that in the first chain $\delta : P \oplus Q \xrightarrow{\sim} P + Q$ is an isomorphism iff $P \cap Q = 0$ and in the second chain $\sigma : M/(P \cap Q) \xrightarrow{\sim} M/P \oplus M/Q$ is an isomorphism iff $M = P + Q$.

(vi) A special case of (v) is the following: Consider any two distinct prime numbers $2 \leq p \neq q \in \mathbb{Z}$. By the Chinese remainder theorem we get $\mathbb{Z}_p \oplus \mathbb{Z}_q = \mathbb{Z}_{pq}$. Thereby the canonical maps become $\iota : \mathbb{Z}_p \to \mathbb{Z}_{pq} : a + p\mathbb{Z} \mapsto aq + pq\mathbb{Z}$ and $\pi : \mathbb{Z}_{pq} \to \mathbb{Z}_q : b + pq\mathbb{Z} \mapsto b + q\mathbb{Z}$. And hence we obtain the short exact sequence of $\mathbb{Z}$-modules

$$0 \to \mathbb{Z}_p \xrightarrow{\iota} \mathbb{Z}_{pq} \xrightarrow{\pi} \mathbb{Z}_q \to 0$$

(3.89) Lemma: (viz. 842)
Let $(R, +, \cdot)$ be a commutative ring. If the following chain of R-modules is exact [that is φ is injective, ψ is surjective and $\mathrm{im}(\varphi) = \mathrm{kn}(\psi)$] then statements (a), (b) and (c) are equivalent

$$0 \to L \xrightarrow{\varphi} M \xrightarrow{\psi} N \to 0$$

(a) There is some homomorphism $\alpha : M \to L$ such that $\alpha\varphi = \mathbb{1}_L$

(b) There is some homomorphism $\omega : N \to M$ such that $\psi\omega = \mathbb{1}_N$

(c) There is an isomorphism $\Phi : M \xrightarrow{\sim} L \oplus N$ such that the following diagram commutes

$$\begin{array}{ccccccccc} 0 & \to & L & \xrightarrow{\varphi} & M & \xrightarrow{\psi} & N & \to & 0 \\ & & = & & \downarrow \Phi & & = & & \\ 0 & \to & L & \xrightarrow{\iota} & L \oplus N & \xrightarrow{\pi} & N & \to & 0 \end{array}$$

Nota That the above diagram in (c) commutes, is to say $\Phi\varphi = \iota$ and $\pi\Phi = \psi$. And in this case we already have $\mathrm{kn}(\alpha) = \mathrm{im}(\omega)$ and M is the (inner) direct sum of the sub-modules

$$M \;=\; \mathrm{kn}(\alpha) \oplus \mathrm{im}(\varphi) \;=\; \mathrm{im}(\omega) \oplus \mathrm{kn}(\psi)$$

(3.90) Corollary: (viz. 845)
Let $(R, +, \cdot)$ be a commutative ring and assume the following short chain of R-modules is exact:

$$0 \to L \xrightarrow{\varphi} M \xrightarrow{\psi} N \to 0$$

If N is free, then (a), (b) and (c) in (3.89) are true, that is there is an isomorphism $\Phi : M \xrightarrow{\sim} L \oplus N$ such that the following diagram commutes

$$\begin{array}{ccccccccc} 0 & \to & L & \xrightarrow{\varphi} & M & \xrightarrow{\psi} & N & \to & 0 \\ & & = & & \downarrow \Phi & & = & & \\ 0 & \to & L & \xrightarrow{\iota} & L \oplus N & \xrightarrow{\pi} & N & \to & 0 \end{array}$$

(3.91) Remark:
We usually are interested in the isomorphism $\Phi : M \xrightarrow{\sim} L \oplus N$. So let us give the construction of this isomorphism that is used in the proof of lemma (3.89): If α is given, then we can give Φ straight away. If conversely ω is given, then we can explicitly give the inverse Φ^{-1} isomorphism instead:

$$\Phi \ : \ M \ \xrightarrow{\sim} \ L \oplus N \ : \ x \mapsto (\alpha(x), \psi(x))$$

$$\Phi^{-1} \ : \ L \oplus N \ \xrightarrow{\sim} \ M \ : \ (u, p) \mapsto \varphi(u) + \omega(p)$$

In (3.90), if N is free, we get the isomorphism Φ by constructing a suitable map $\omega : N \to M$: Let $\{ n_i \mid i \in I \}$ be a basis of N and for any $i \in I$ choose some $m_i \in M$ such that $\psi(m_i) = n_i$. Then we can define $\omega(\sum_i a_i n_i) := \sum_i a_i m_i$ and thereby get Φ as above.

The next few theorems will be concerned with chains of modules. While this may look a little weird, if this is your first encounter with this notion, it truly is a powerful language, that will be developed further. In fact there is an entire mathematical discipline called *homological algebra* dedicated to studying these objects. And the method of using chains and diagrams is also known as *diagram-chasing*. So let us start with some fundamental properties of chains:

(3.92) Lemma: (viz. 992)
Let $(R, +, \cdot)$ be a ring, $n \geq 2$ and for any $i \in 1 \dots n$ consider $\varphi_i : M_{i-1} \to M_i$ and $\psi_i : N_{i-1} \to N_i$ some R-module homomorphisms. Also suppose, that for any $i \in 0 \dots n$ there is some isomorphism of R-modules $\Phi_i : M_i \xrightarrow{\sim} N_i$ such that we may regard the following diagram

$$\begin{array}{ccccccccc} M_0 & \xrightarrow{\varphi_1} & M_1 & \xrightarrow{\varphi_2} & M_2 & \to \dots & \xrightarrow{\varphi_n} & M_n \\ \updownarrow & & \updownarrow & & \updownarrow & & & \updownarrow \\ N_0 & \xrightarrow{\psi_1} & N_1 & \xrightarrow{\psi_2} & N_2 & \to \dots & \xrightarrow{\psi_n} & N_n \end{array}$$

Suppose this diagram commutes, that is for any $i \in 1 \dots n$ we have $\Phi_i \varphi_i = \psi_i \Phi_{i-1}$. Then the following two statements are equivalent

(a) The chain $M_0 \to M_1 \to M_2 \to \cdots \to M_n$ is exact (resp. a complex)

(b) The chain $N_0 \to N_1 \to N_2 \to \cdots \to N_n$ is exact (resp. a complex)

The following lemma may seem a little strange at a first glance: It studies the effect of pull-back and push-forward of homomorphisms of modules. The right setting in which to formulate this is the new-forged language of chains of modules. Here all the properties take a neat compact form - though the punch of this approach will only later reveal itself, when we regard tensor products of modules.
In the language of homological algebra it could be put as: The push-forward is a left-exact, covariant functor, whereas the pull-back is a left-exact contra-variant functor. But let's not get ahead of ourselves and just focus on one of the staging points of homological algebra:

(3.93) Lemma: (viz. 992)
Let $(R,+,\cdot)$ be a (not necessarily commutative) ring and consider the R-modules U, V, W and M such that the following chain of modules is exact

$$0 \to U \xrightarrow{\varphi} V \xrightarrow{\psi} W$$

Recall the definition of the push-forward $\varphi_* : \mathcal{L}(M,U) \to \mathcal{L}(M,V)$ defined by $\varphi_*(f) = \varphi f$, then the following chain of R-modules is exact, as well

$$0 \to \mathcal{L}(M,U) \xrightarrow{\varphi_*} \mathcal{L}(M,V) \xrightarrow{\psi_*} \mathcal{L}(M,W)$$

Conversely suppose we have an exact chain of modules of the following form

$$U \xrightarrow{\varphi} V \xrightarrow{\psi} W \to 0$$

And recall the definition of the pull-back $\varphi^* : \mathcal{L}(V,M) \to \mathcal{L}(U,M)$ defined by $\varphi^*(g) = g\varphi$, then the following chain of R-modules is exact, as well

$$0 \to \mathcal{L}(W,M) \xrightarrow{\psi^*} \mathcal{L}(V,M) \xrightarrow{\varphi^*} \mathcal{L}(U,M)$$

The following theorem is somewhat of an inverse of the lemma above: It grants the exactness of the original chain of modules, iff all chains of homomorphism modules are exact. The proof just chooses clever candidates for modules L and N in order to establish the exactness of the original chain. However we will vastly generalize this statement in category theory in section 11.2.

(3.94) Lemma: (viz. 993)
Yoneda's Lemma: Let $(R,+,\cdot)$ be any ring, $n \geq 2$ and for any $i \in 1 \dots n$ consider a homomorphisms $\varphi_i : M_{i-1} \to M_i$ of R-modules. We will abbreviate the following chain of R-modules by $\star$

$$\star \;:=\; M_0 \xrightarrow{\varphi_1} M_1 \xrightarrow{\varphi_2} M_2 \to \dots \xrightarrow{\varphi_n} M_n$$

(i) If for any R-module L the following chain of R-modules is exact, then the original chain $\star$ already was exact, itself

$$\mathcal{L}(L,M_0) \xrightarrow{(\varphi_1)_*} \mathcal{L}(L,M_1) \xrightarrow{(\varphi_2)_*} \mathcal{L}(L,M_2) \to \dots \xrightarrow{(\varphi_n)_*} \mathcal{L}(L,M_n)$$

(ii) If for any R-module N the following chain of R-modules is exact, then the original chain $\star$ already was exact, itself

$$\mathcal{L}(M_n,N) \xrightarrow{(\varphi_1)^*} \mathcal{L}(M_{n-1},N) \to \dots \xrightarrow{(\varphi_2)^*} \mathcal{L}(M_1,N) \xrightarrow{(\varphi_1)^*} \mathcal{L}(M_0,N)$$

3.10 Rank of Modules

Remember that in section 3.7 we defined the **rank** of an R-module to be the minimal cardinality of a generating set of M. Formally that is the definition

$$\mathrm{rank}(M) \;:=\; \min\{\,|X| \mid X \subseteq M,\ M = \mathrm{Lh}(X)\,\}$$

That is: If $I = \mathrm{rank}(M)$ then there is some subset $\{\,m_i \mid i \in I\,\} \subseteq M$ that generates M as its linear hull $M = \mathrm{Lh}\{\,m_i \mid i \in I\,\}$. And conversely, if $X \subseteq M$ generates $M = \mathrm{Lh}(X)$, then $|I| \leq |X|$.
Be careful however - a *minimal set of generators*, need not have *minimal cardinality*! E.g. the set $\{\,2,3\,\} \subseteq \mathbb{Z}$ is a minimal set of generators of the $\mathbb{Z}$-module $\mathbb{Z}$. That is $\{\,2,3\,\}$ generates $\mathbb{Z} = \langle 2,3\rangle_{\mathsf{m}}$ and of course neither $\{2\}$ nor $\{3\}$ generates $\mathbb{Z}$. However we have $\mathrm{rank}(\mathbb{Z}) = 1$, as $\mathbb{Z} = \langle 1\rangle_{\mathsf{m}}$ is clear. As we have seen in (3.64.(iv)) this is quite different in the case of modules over skew-fields. But even the base ring $\mathbb{Z}$ (and what better ring is there to wish for?) gives rise to such peculiarities.
Let us now study the basic properties of the rank of modules, but be ready for some nasty surprises, as the theory will take some twists and turns. Many properties one would think of as evident will be untrue, unless we deal with nice rings and modules. Others will hold true in astounding generality.

(3.95) Example: (viz. 995)

(i) The ring $\mathbb{Z}$ is an UFD (in fact even a PID) that contains infinitely many prime elements. That is the following set contains infinitely elements

$$\mathbb{P} \;:=\; \{\,p \in \mathbb{Z} \mid 2 \leq p \text{ is prime}\,\}$$

(ii) The set $\mathbb{Q}$ regarded as an $\mathbb{Z}$-module is has no finite set of generators. Hence it is of countably infinite rank. A generating set is being given by

$$P \;:=\; \left\{\, \frac{1}{p^k} \mid p \in \mathbb{P}, k \in \mathbb{N} \,\right\}$$

(3.96) Proposition: (viz. 1001)
Let $(R,+,\cdot)$ be an arbitrary ring and consider any two R-modules M and N. If now $\varphi : M \twoheadrightarrow N$ is a surjective R-linear map (an R-module epimorphism), then N cannot exceed M in rank:

$$\mathrm{rank}(N) \;\leq\; \mathrm{rank}(M)$$

Likewise, if $P \leq_{\mathsf{m}} M$ is an R-sub-module of M, then we get the following inequality for the rank of M

$$\mathrm{rank}(M) \;\leq\; \mathrm{rank}(P) + \mathrm{rank}\left(M \Big/ P\right)$$

(3.97) Proposition: (viz. 1005)
Let $(R,+,\cdot)$ be a commutative, non-zero ring $R \neq 0$. If now M and N are free R-modules, then M and N are isomorphic as R-modules, if and only if they share the same rank, formally that is

$$M \;\cong_{\mathfrak{m}}\; N \quad\Longleftrightarrow\quad \operatorname{rank}(M) \;=\; \operatorname{rank}(N)$$

In particular: If M is free of rank $I = \operatorname{rank}(M)$, then M is isomorphic to the Euclidean R-module $M \cong_{\mathfrak{m}} R^{\oplus I}$ presented in (3.60). If $\{ m_i \mid i \in I \}$ is an R-basis of M, then an isomorphism is given by

$$R^{\oplus I} \;\xrightarrow{\sim}\; M \;:\; (a_i) \mapsto \sum_{i\in I} a_i m_i$$

(3.98) Remark:
The above proposition (3.96) enables us to control the rank of M by controling the rank of a sub-module $P \leq_{\mathfrak{m}} M$ (and of the quotient M/P). On the other hand one is tempted to expect that the rank of a sub-module P of M cannot exceed the rank of the containing module M. However nothing is farther from the truth. Consider the ring $R = \mathbb{Q}[t_i \mid i \in I]$ where I is an arbitrary index set. If $I = 1 \ldots n$ then we have the usual polynomial ring $\mathbb{Q}[t_1, \ldots, t_n]$ that is a very tame ring - a noetherian integral domain. If we now regard the ring $M = R$ as an R-module itself, it is clear, that $\operatorname{rank}(M) = 1$. However, hell breaks loose, once we take a look at the ideal $\mathfrak{m} := \langle t_i \mid i \in I \rangle_{\mathfrak{i}} \trianglelefteq_{\mathfrak{i}} R$. If we take $\mathfrak{m}$ as an R-sub-module of $M = R$, then the rank of $\mathfrak{m}$ is no less than

$$\operatorname{rank}(M) \;=\; 1 \;\leq\; |I| \;=\; \operatorname{rank}(\mathfrak{m})$$

By primary decomposition it is easy to see, that $T := \{ t_i \mid i \in I \}$ is a minimal generating set $\mathfrak{m} = \operatorname{Lh}_R(T)$ and in fact it hits the rank. That is the sub-module $\mathfrak{m}$ of M can have arbitrarily large rank, even though M is of rank 1! Modules can have astoundligly vast space within themselves! The reason is that all those t_i do not take up much space, they are all linearly dependent: $t_j t_i - t_i t_j = 0$.

So the question arises how to control the space *inside* a module. One of the best answers one can give refers to *free* sub-modules of M - these cannot be larger than M itself - refer to (3.99.(iv)). Also note that as long as I is finite R is noetherian. And in fact sub-modules of finitely generated modules over noetherian rings are again finitely generated. This will be the topic of section 3.11. Finally note that in case of $|I| = 1$ we even had $\operatorname{rank}(\mathfrak{m}) = \operatorname{rank}(M)$. But in this case R even is a PID and in fact finitely generated modules over PIDs are very well-behaved.

(3.99) Lemma: (viz. 1001)
Consider a commutative ring $(R,+,\cdot)$ and an R-module M. Further suppose, that $R \neq 0$ is non-zero. Then the following statements are true

(i) If $\{ x_1, \ldots, x_n \} \subseteq M$ (where $n \in \mathbb{N}$) generates M as an R-module, then any $n+1$ elements of M are R-linearly dependent. That is: Given $y_1, \ldots, y_n, y_{n+1} \in M$ there are some $a_1, \ldots, a_n, a_{n+1} \in R$ such that $a_k \neq 0$ for some $k \in 1 \ldots n+1$ and:

$$a_1 y_1 + \cdots + a_n y_n + a_{n+1} y_{n+1} \;=\; 0$$

(ii) If $\{ m_1, \ldots, m_n \} \subseteq M$ (where $n \in \mathbb{N}$) is an R-basis of M and $\{ x_1, \ldots, x_n \}$ generates M as an R-module, then $\{ x_1, \ldots, x_n \}$ is a basis, as well.

(iii) If $B \subseteq M$ is an R-basis of M then the cardinality of B equals the rank of M, formally that is

$$\text{rank}(M) \quad = \quad |B|$$

(iv) If $F \leq_{\mathsf{m}} M$ is a free sub-module of M, then it's rank does not exceed the rank of M, formally

$$\text{rank}(F) \quad \leq \quad \text{rank}(M)$$

(3.100) Remark:
Dimension: In general, for an arbitrary ring $(R, +, \cdot)$ and a free R-module M the **dimension** is set to be the minimal cardinality of an R-basis of M

$$\dim(M) \quad := \quad \min\{ \, |B| \mid B \subseteq M \text{ is a basis of } M \, \}$$

From this definition it is clear that the rank of M does not exceed the dimension of M [because any base B of M already generates $M = \text{Lh}(B)$], that is

$$\text{rank}(M) \quad \leq \quad \dim(M)$$

In this light lemma (3.99.(iii)) tells us that in case of a commutative ring R *all* bases of a free R-module M share the same cardinality, namely the rank of M. In particular - if R is commutative and M is free - we even have the equality of

$$\dim(M) \quad = \quad \text{rank}(M)$$

Thus - for commutative rings - the dimension is not a new invariant. However it is customary to refer to the dimension, rather than the rank, when operating with free modules. Also we have seen in (3.64.(vi)) that for any skew-field $(S, +, \cdot)$ and any S-vector-space V all bases share the same cardinality, as well. It is easy to see that this is the rank again

$$\dim(V) \quad = \quad \text{rank}(V)$$

Prob as $\text{rank}(V) \leq \dim(V)$ is always true, it remains to prove $\dim(V) \leq \text{rank}(V)$. Thus let $X \subseteq M$ be a generating set of M with $|X| = \text{rank}(M)$. Then by the basis selection theorem (3.58) there is a subset $B \subseteq X$ such that B is a basis of M. In particular $\dim(S) = |B| \leq |X| = \text{rank}(X)$.

After these two important cases, commutative rings and skew-fields, on might be tempted to think that generally (over arbitrary rings) all bases share the same cardinality, preferably the rank of M. This is untrue however. There are some modules over non-commutative rings, that have bases of different size. We have given one such example in (3.84).

(3.101) Definition:
Let $(R,+,\cdot)$ be an arbitrary ring and M be an R-module. Then a subset $L \subseteq M$ is said to be a **maximal linear independent set** of M, iff it is R-linearly independent and for any other R-linearly independent set $L' \subseteq M$ we get the implication

$$L \subseteq L' \implies L = L'$$

As we will see in (3.102.(viii)), if R is an integral domain then all maximal linear independent subsets of M are of the same cardinality. Hence in this case we may define the **linear freedom** of M to be

$$\text{free}(M) := |L| \text{ for some maximal linear independent set } L \subseteq M$$

(3.102) Corollary: (viz. 1005)
Let $(R,+,\cdot)$ be an arbitrary ring and M be an R-module. Then we obtain the following statements concerning maximal linear independent subsets of M

(i) Any linear independent set in M is contained in a maximal linear independent set. That is: If $L \subseteq M$ is R-linearly independent, then there is a maximal linear independent set $L^* \subseteq M$ with

$$L \subseteq L^*$$

(ii) If $R \neq 0$ is not the zero ring, L is a maximal linear independent set and $x \in M$ is any element of M, then there is some $a \in R$ satisfying the following property

$$a \neq 0 \quad \text{and} \quad ax \in \text{Lh}(L)$$

(iii) Recall that M is said to be a *torsion module*, iff for any $x \in M$ there is some $a \in R$, $a \neq 0$ such that $ax = 0$. If now R is an integral domain, then this property translates into

$$\text{free}(M) = 0 \iff M \text{ is a torsion module}$$

(iv) If $L \subseteq M$ is a linear independent set, then the sub-module $F := \text{Lh}(L)$ generated by L is a free R-module with basis L. In particular if $R \neq 0$ is a non-zero commutative ring then the cardinality of any any linear independent set L in M is bounded by the rank of M. That is

$$|L| \leq \text{rank}(M)$$

(v) Let R be an integral domain and $L \subseteq M$ be a linearly independent set in M. We denote by by $F := \text{Lh}(L) \leq_{\mathfrak{m}} M$ the free sub-module of M generated by L. Finally consider finitely many elements $x_1, x_2, \ldots, x_n \in M$ (where $n \in \mathbb{N}$) such that

- $M = F + \text{Lh}\{ x_1, x_2, \ldots, x_n \}$
- $\forall\, i \in 1 \ldots n : L \cup \{x_i\}$ is linearly dependent

Then L is a maximal linearly independent subset of M, M/F is a torsion module and in particular the linear freedom of M equals the dimension of F:

$$\mathrm{free}(M) \;=\; |L| \;=\; \dim(F)$$

(vi) In a more fancy language (ii) can be put as: If $R \neq 0$ is a non-zero ring and L is a maximal linear independent set, with $F := \mathrm{Lh}(L)$ then the quotient M/F is a torsion R-module. That is

$$\forall\, z \in M\big/_F \;\; \exists\, a \in R \;\text{ such that } a \neq 0 \;\text{ and } az = 0$$

Conversely if $F \leq_{\mathsf{m}} M$ is a free sub-module of M such that the quotient M/F is a torsion module, then any basis $B \subseteq F$ is a maximal linear independent set $B \subseteq M$ in M.

(vii) Let now R even be an integral domain and consider a linearly independent set $L \subseteq M$. Further for any $x \in L$ let $a_x \in R$ be any non-zero element $a_x \neq 0$ of R. Then the set $L' := \{\, a_x x \mid x \in L \,\}$ is linearly independent again and $|L| = |L'|$.

(viii) If R even is an integral domain, then any two maximal linear independent sets have the same cardinality. That is: If K and $L \subseteq M$ are any two maximal linear independent sets, then

$$|K| \;=\; |L| \;\leq\; \mathrm{rank}(M)$$

(ix) If R is an integral domain and $P \leq_{\mathsf{m}} M$ is any sub-module of M, then linear freedom of M equals the sum of the linear freedoms of P and the quotient M/P, formally that is

$$\mathrm{free}(M) \;=\; \mathrm{free}(P) + \mathrm{free}\left(M\big/_P\right)$$

(x) $(\diamondsuit)$ Let R be an integral domain and denote its quotient field by $E := \mathrm{QUOT}(R)$. Then the linear freedom of M is just the dimension of the scalar extension of M to E, formally that is

$$\mathrm{free}_R(M) \;=\; \dim_E(E \otimes_R M)$$

(3.103) Remark:

(i) It is clear that in the case of a free R-module M over an integral domain R the linear freedom equals the dimension, as any basis of M already is a maximal linear independent subset

$$M \text{ free} \;\Longrightarrow\; \mathrm{free}(M) \;=\; \dim(M)$$

However, if M is not free, then the rank of M may well be larger, than the linear freedom. The following two examples (ii) and (iii) should enlighten the situation

$$\text{gererally} \;\Longrightarrow\; \mathrm{free}(M) \;\leq\; \mathrm{rank}(M)$$

(ii) Consider the $\mathbb{Z}$-module $M := \mathbb{Z}^f \oplus (\mathbb{Z}_n)^k$ for some arbitrary numbers $f, k \in \mathbb{N}$. As $F := \mathbb{Z}^f \oplus 0$ is a free sub-module $F \leq_{\mathfrak{m}} M$ and $M/F = 0 \oplus (\mathbb{Z}_n)^k$ is a torsion module (3.102.(vi)) implies that the linear freedom of M is precisely f. However $(\mathbb{Z}_n)^k$ contributes to the rank of M and hence

$$f \;=\; \text{free}(M) \;\leq\; \text{rank}(M) \;=\; f + k$$

This is to be interpreted in the following way: The rank yields a more accurate description of the module, hence (3.97) - it regards every part of M. The linear freedom only is the dimension of the largest free module inside M, it neglects components with torsion. This makes it is easier to control, whereas the rank can explode incontrollably by picking up torsion. Just compare (3.102.(ix)) to (3.96), the inequality now is an equality.

(iii) Consider the integral domain $R := \mathbb{Z}[t]$ and regard the (maximal) ideal $\mathfrak{m} := \langle 2, t \rangle_{\mathfrak{i}} \trianglelefteq_{\mathfrak{i}} R$ as an R-module. Then $\mathfrak{m}$ has a linear freedom of 1, as $\{t\}$ is a maximal linear independent set (any other $f \in R$ would yield a linearly dependent set). The rank is 2 however ($\mathfrak{m}$ is not a principal ideal). This can happen, as $R/\mathfrak{m} \cong_{\mathfrak{m}} \mathbb{Z}_2$ has torsion. Also note that $\mathfrak{m}$ is not a free module, just because it is not a principal ideal.

(3.104) Theorem: (viz. 1009)
Modules over PIDs: Let $(R, +, \cdot)$ be a PID and let M be a module over R. If now $P \leq_{\mathfrak{m}} M$ is any sub-module of M, then we get the following statements

(i) If M is free, then P is free, as well and its dimension does not exceed the dimension of M, that is

$$\dim(P) \;\leq\; \dim(M)$$

(ii) If M is finitely generated, then P is finitely generated, as well. Generally the rank of P does not exceed the rank of M. That is

$$\text{rank}(P) \;\leq\; \text{rank}(M)$$

(iii) If M is finitely generated, then M is free if and only if it is torsion free. That is we have the equivalence of the statements

$$M \text{ free} \quad\Longleftrightarrow\quad \text{TOR}(M) \;=\; 0$$

(iv) If M is finitely generated, then M is isomorphic to the (exterior) direct sum of the free R-module $M/\text{TOR}(M)$ and the torsion-module $\text{TOR}(M)$. Formally again

$$M \;\cong_{\mathfrak{m}}\; M \Big/ _{\text{TOR}(M)} \oplus \text{TOR}(M)$$

(3.105) Remark:

(i) In section (3.7) we have seen that, if R is a skew-field, then any R-module M is free already. In particular any sub-module $P \leq_{\mathfrak{m}} M$ is free, as well. Thus, concerning skew-fields, we have not gained something new, but R has been a PID here.

(ii) If R is not a PID, then this result need not be true! Consider the base ring $R = \mathbb{Z}[s,t]$. Note that this ring is a noetherian integral domain, the next-best thing apart from a PID. We take $M = R$ to be the free R-module of rank 1. Then the sub-module $P := \mathrm{Lh}\{ s,t \}$ is not free, as it contains the linear dependence $t \cdot s - s \cdot t = 0$. And P also has rank 2 over R.

(iii) The proof of this theorem uses the well-known but rarely used *well-ordering theorem* (0.30), that is a consequence of the axiom of choice (in fact it even is equivalent to the AC on the basis of the other axioms of set-theory). It states, that on any non-empty set I there is a total order $\leq$ that such that every non-empty subset $H \subseteq I$ contains a minimal element. Formally for any $H \subseteq I$ with $H \neq \emptyset$ there is some $m \in H$ such that for any $h \in H$ we get $h \leq m \implies h = m$. In case of a finite set $I = \{ i_1, \ldots, i_n \}$ this is evident, just define $\leq$ to be any linear order $i_1 < i_2 < \cdots < i_n$ of these elements. But in fact such an order exists for arbitrarily large sets I, which might come as a little surprise.

(iv) In fact the proof shows a little more: If $\{ m_i \mid i \in I \}$ is a basis of M, then there is a subset $H \subseteq I$ of I such that we find a basis $\{ p_i \mid i \in H \}$ of P, where any p_j ($j \in H$) is of the form

$$p_j \;=\; a_j m_j + \sum_{i<j} b_{i,j} m_i$$

for some coefficients a_j and $b_{i,j} \in R$. We will be able to refine this result for finitely generated R-modules, by precisely describing their structure (up to isomorphy).

3.11 Noetherian Modules

In the previous section we have seen, that the size (in terms of the *rank*) of a sub-module P of M can be very hard to control. However there are those well-behaved modules for which the rank remains finite at last. If $M = R$ is the base ring itself, the sub-modules of M are the ideals of M. And a ring in which all ideals are finitely generated has been called *noetherian*. So we will generalize this notion to the case of modules over a commutative ring and it turns out *noetherian* modules have a whole bunch of nice properties that we are about to explore:

(3.106) Definition: (viz. 891)
Let $(R, +, \cdot)$ be a commutative ring and M be an R-module. Then M is said to be a **noetherian** module, iff it satisfies one of the following three equivalent conditions:

(a) M satisfies the *ascending chain condition* of sub-modules - that is every ascending chain of sub-modules of M becomes stationary. I.e. any sequence (P_k) (where $k \in \mathbb{N}$) of sub-modules $P_k \leq_{\mathsf{m}} M$ that satisfies

$$P_0 \subseteq P_1 \subseteq \ldots \subseteq P_k \subseteq P_{k+1} \subseteq \ldots$$

becomes eventually constant - that is there is some $s \in \mathbb{N}$, such that the chain actually looks like

$$P_0 \subseteq P_1 \subseteq \ldots \subseteq P_s = P_{s+1} = \ldots$$

(b) Every non-empty family $\mathcal{P} \subseteq \mathrm{Subm}(M)$, $\mathcal{P} \neq \emptyset$ of sub-modules of M contains a maximal element. I.e. there is some $P^* \in \mathcal{P}$ that satisfies the property

$$\forall\, P \in \mathcal{P} \;:\; P^* \subseteq P \implies P = P^*$$

(c) Every sub-module P of M is finitely generated. That is for any sub-module $P \leq_{\mathsf{m}} M$ there are some $\{ x_1, \ldots, x_n \} \subseteq P$, that generate P as an R-module

$$P = \mathrm{Lh}(x_1, \ldots, x_n)$$

(3.107) Definition:
Let $(R, +, \cdot)$ be a commutative ring and M be an R-module. Then M is said to be a **artinian** module, iff it satisfies one of the following two equivalent conditions:

(a) M satisfies the *descending chain condition* of sub-modules - that is every descending chain of sub-modules of M becomes stationary. I.e. any sequence (P_k) (where $k \in \mathbb{N}$) of sub-modules $P_k \leq_{\mathsf{m}} M$ that satisfies

$$P_0 \supseteq P_1 \supseteq \ldots \supseteq P_k \supseteq P_{k+1} \supseteq \ldots$$

becomes eventually constant - that is there is some $s \in \mathbb{N}$, such that the chain actually looks like

$$P_0 \supseteq P_1 \supseteq \ldots \supseteq P_s = P_{s+1} = \ldots$$

(b) Every non-empty family $\mathcal{P} \subseteq \mathrm{Subm}(M)$, $\mathcal{P} \neq \emptyset$ of sub-modules of M contains a minimal element. I.e. there is some $P_* \in \mathcal{P}$ such that

$$\forall\, P \in \mathcal{P} \;:\; P \subseteq P_* \implies P = P_*$$

Prob the equivalence of these statements is no specialty of modules, but a general truism for partial orders. In this case the order in question is $P \leq Q$ defined by $Q \subseteq P$. Then this equivalence here is just an application of (0.25).

(3.108) Remark:
The notion of a noetherian (resp. artinian) module is closely related to the notion of a noetherian (resp. artinian) ring. In fact if we regard a commutative ring R as a module over itself, then the ideals $\mathfrak{a} \trianglelefteq_{\mathsf{i}} R$ are precisely the sub-modules $\mathfrak{a} \leq_{\mathsf{m}} R$ of R. Hence by property (a) we see, that R is noetherian (resp. artinian) as an R-module, if and only if it is noetherian (resp. artinian), as a ring.

(3.109) Example:
Clearly $\mathbb{Z}$ is a noetherian ring (it even is a PID) and hence a noetherian $\mathbb{Z}$-module. However $\mathbb{Z}$ is not artinian, as there is an infinitely descending chain of ideals, that does not stabilize, given by

$$\mathbb{Z} \supset 2\mathbb{Z} \supset 4\mathbb{Z} \supset \ldots \supset 2^k\mathbb{Z} \supset \ldots$$

Conversely pick up any prime $p \in \mathbb{Z}$ and regard the sub-ring $\mathbb{Z}[1/p] \leq_{\mathsf{r}} \mathbb{Q}$ of $\mathbb{Q}$ generated by $1/p \in \mathbb{Q}$. Clearly $\mathbb{Z} \leq_{\mathsf{r}} \mathbb{Z}[1/p]$ is a sub-ring as well, and hence a sub-module. Therefore we may regard the quotient module of $\mathbb{Z}[1/p]$ by $\mathbb{Z}$ as a $\mathbb{Z}$-module again

$$I(p) \;:=\; \mathbb{Z}[1/p] \,\big/\, \mathbb{Z} \;=\; \left\{ x + \mathbb{Z} \mid \exists\, k \in \mathbb{N} : p^k x \in \mathbb{Z} \right\}$$

By the way, this is just the p-primary component of $\mathbb{Q}/\mathbb{Z}$. Then $I(p)$ is not noetherian, as there is an infinitely ascending chain of sub-modules of $I(p)$, that does not stabilize

$$\mathbb{Z} \subset \mathbb{Z}\left(\frac{1}{p} + \mathbb{Z}\right) \subset \mathbb{Z}\left(\frac{1}{p^2} + \mathbb{Z}\right) \subset \mathbb{Z}\left(\frac{1}{p^3} + \mathbb{Z}\right) \subset \ldots$$

However it can be shown, that $I(p)$ is a artinian module. Recall that in the case of commutative rings, any artinian ring already is noetherian. Yet $I(p)$ is *not* noetherian: In the case of modules, artinian does not imply noetherian and artinian modules need not be finitely generated!

(3.110) Example: (viz. 894)

- Let us consider the rationals $\mathbb{Q}$ as a $\mathbb{Z}$-module canonically. Then for any $0 \neq b \in \mathbb{Z}$ we clearly get a sub-module of $\mathbb{Q}$ by virtue of

$$M_b \;:=\; \mathbb{Z}\frac{1}{b} \;=\; \left\{ \frac{a}{b} \;\middle|\; a \in \mathbb{Z} \right\}$$

And any finitely generated sub-module P of $\mathbb{Q}$ is contained in a sub-module of this kind. But M_b is not $\mathbb{Q}$, e.g. it lacks $1/2b$, so that we can conclude, that $\mathbb{Q}$ is not finitely generated, as a $\mathbb{Z}$-module.

- If $a \mid b$, say $au = b$ than $1/a = u/b \in M_b$ such that $M_a \subseteq M_b$. If now p is any prime number, then we therefore find an infinitely ascending chain of sub-modules of $\mathbb{Q}$ (i.e. $\mathbb{Q}$ is not *noetherian*)

$$\mathbb{Z} \;=\; M_1 \;\subset\; M_p \;\subset\; M_{p^2} \;\subset\; M_{p^3} \;\subset\; \ldots$$

- Another kind of $\mathbb{Z}$-sub-module of $\mathbb{Q}$ is given by the following construction: Choose a prime number p, then the set D_p of all fractions whose denominator is *not* divisible by p is a sub-module of $\mathbb{Q}$:

$$D_p \;:=\; \left\{ \frac{a}{b} \in \mathbb{Q} \;\middle|\; p \not| \, b \right\}$$

 In fact this is just the localization $\mathbb{Z}_{(p)} := \mathbb{Z}_{\mathfrak{p}}$ where $\mathfrak{p} = p\mathbb{Z}$, but $D_p \;\leq_{\mathsf{m}}\; \mathbb{Q}$ can also be seen elementary: If a/b and $c/d \in D_p$, then $a/b + c/d = (ad + bc)/(ad)$. Suppose $p \mid ad$, then, since p is prime we had $p \mid a$ or $p \mid d$, which are both untrue, by assumption, hence $a/b + c/d \in D_p$ again. And $k(a/b) = (ka)/b \in D_p$ is clear, for any $k \in \mathbb{Z}$ and $a/b \in D_p$. Thus D_p is closed under addition and scalar multiplication, i.e. a submudule.

- The same construction holds true for any set $P \subseteq \mathbb{Z}$ of prime numbers, let D_P be the set of all fractions whose denominator is *not* divisible by any prime $p \in P$

$$D_P \;:=\; \left\{ \frac{a}{b} \in \mathbb{Q} \;\middle|\; \forall\, p \in P : p \not| \, b \right\} \;=\; \bigcap_{p \in P} D_p$$

 Then by the same reasoning as above it is clear that D_P is a sub-module of $\mathbb{Q}$. And trivially we have $D_Q \subseteq D_P$ whenever $P \subseteq Q \subseteq \mathbb{Z}$ are sets of prime numbers. Thus we also find an infinitely descending chain of sub-modules in $\mathbb{Q}$ (i.e. $\mathbb{Q}$ is not *artinian*)

$$\ldots \;\subset\; D_{\{2,3,5\}} \;\subset\; D_{\{2,3\}} \;\subset\; D_2 \;\subset\; D_\emptyset \;=\; \mathbb{Q}$$

- In the proof we present a reasoning that shows, that $\mathbb{Q}$ does not contain any proper, maximal $\mathbb{Z}$-sub-module. That is: If $U \;\leq_{\mathsf{m}}\; \mathbb{Q}$ is a sub-module with $P \neq \mathbb{Q}$, then there always is another sub-module $V \;\leq_{\mathsf{m}}\; \mathbb{Q}$ in between: $U \subset V \subset \mathbb{Q}$. In this sense the space inside $\mathbb{Q}$, if we regard it as a $\mathbb{Z}$-module, is infinte.

(3.111) Theorem: (viz. 892)
Let $(R, +, \cdot)$ be a commutative ring and M, N be R-modules. We also regard two sub-modules P, $Q \;\leq_{\mathsf{m}}\; M$ of M. In order to avoid giving two completely analogous lists of theorems, let us abbreviate

$$\star \;\in\; \{\, \text{noetherian, artinian} \,\}$$

(i) M is a $\star$ module if and only if both P and the quotient M/P are $\star$ modules. Formally that is

$$M \text{ is } \star \quad\Longleftrightarrow\quad P \text{ and } {}^{M}\!\Big/_{P} \text{ are } \star$$

(ii) If both quotient modules M/P and M/Q are $\star$ modules, then the quotient $M/(P \cap Q)$ is a $\star$ module again. Formally that is the implication

$$M\Big/_P \text{ and } M\Big/_Q \text{ are } \star \implies M\Big/_{P\cap Q} \text{ is } \star$$

(iii) If both P and Q are $\star$ modules, then so is their sum $P+Q \leq_{\mathfrak{m}} M$. Formally that is the implication

$$P \text{ and } Q \text{ are } \star \implies P+Q \text{ is } \star$$

(iv) If both M and N are $\star$ modules, then the direct sum $M \oplus N$ of M and M is a $\star$ module again and vice versa. Formally that is the equivalence

$$M \text{ and } N \text{ are } \star \iff M \oplus N \text{ is } \star$$

(v) The epimorphic image of a $\star$ module is $\star$ again. That is: If $\varphi : M \to N$ is a surjective homomorphism of R-modules and M is a $\star$ module, then so is N. Formally that is the implication

$$M \twoheadrightarrow N \text{ and } M \text{ is } \star \implies N \text{ is } \star$$

(vi) If M is a finitely generated R-module and R is a $\star$ ring, then M already is a $\star$ module. Formally

$$M \text{ finitely generated and } R \text{ is } \star \implies M \text{ is } \star$$

(vii) If L, M and N are R-modules and $0 \to L \to M \to N \to 0$ is a short exact sequence of R-modules, then we get the equivalence of the statements

$$M \text{ is } \star \iff L \text{ and } N \text{ are } \star$$

(3.112) Remark:
It is clear that the above statements (ii), (iii) and (iv) can be generalized to finitely many (sub)-modules. E.g. if P_1 to $P_n \leq_{\mathfrak{m}} M$ are finitely many sub-modules of M, then we obtain the following implication

$$\forall\, i \in 1 \ldots n \,:\, M\Big/_{P_i} \text{ is } \star \implies M\Big/_{P_1 \cap P_2 \cap \cdots \cap P_n} \text{ is } \star$$

Prob this can be easily seen by induction on n: The case $n = 1$ is trivial and for the induction step just let $P := P_1$ and $Q := P_2 \cap \cdots \cap P_n$ and use the respective theorem.
The following proposition shows that in case of vector spaces there is no difference between artinian and noetherian modules, as both are the finiteness of the dimension of the vector space. We will generalize this theorem soon, but in order to do this we first have to find a suitable substitute for the dimension, in case the module in question is not over a field. This notion will be the *length*, an invariant that controls the maximal number of subspaces that can be stacked in M. So let us start with this easy to prove

(3.113) Proposition: (viz. 894)
Let $(F, +, \cdot)$ be a field and V be an F-vector space. Then V is noetherian resp. artinian if and only if it is finite dimensional. That is the following three statements are equivalent:

(a) V is artinian

(b) V is noetherian

(c) V is finite-dimensional

(3.114) Definition: (viz. 895)
Let $(R, +, \cdot)$ be an arbitrary ring and M be an R-module. Then M is said to be a **simple** R-module if $M = 0$ and M has no proper sub-modules. That is $M = 0$ and it satisfies one of the following two equivalent properties:

(a) For any sub-module $P \leq_{\mathfrak{m}} M$ of M we either have $P = 0$ or $P = M$

(b) Any non-zero element of M generates M as an R-module, that is for any $x \in M$ with $x \neq 0$ we already get $M = Rx$.

And if R is commutative, we obtain the following third equivalent statement

(c) There is some maximal ideal $\mathfrak{m} \trianglelefteq_{\mathfrak{i}} R$ of R such that M is isomorphic to the quotient ring $R/\mathfrak{m}$ as an R-module, formally that is

$$\exists\, \mathfrak{m} \in \operatorname{Smax}(R) \text{ such that } M \cong_{\mathfrak{m}} R \Big/ \mathfrak{m}$$

Let $(R, +, \cdot)$ be an arbitrary ring and M be an R-module. Then M is said to be **semi-simple**, iff M can be decomposed into a direct sum of simple sub-modules. That is there is an arbitrary family $M_i \leq_{\mathfrak{m}} M$ of sub-modules (where $i \in I$), such that M_i is a simple R-module (for any $i \in I$) and M is the inner direct sum of these simple sub-modules M_i

$$M = \bigoplus_{i \in I} M_i$$

(3.115) Definition:
Let $(R, +, \cdot)$ be a commutative ring and M be an R-module. Then the tuple $(M_0, M_1, \ldots, M_r)$ is said to be a **composition series** of M, iff the M_i form an ascending chain of sub-modules $M_i \leq_{\mathfrak{m}} M$

$$0 = M_0 \subset M_1 \subset \ldots \subset M_r = M$$

such that for any $i \in 1 \ldots r$ the quotient module M_i / M_{i-1} is simple. And by (3.114) this can be put as: For any $i \in 1 \ldots r$ and any sub-module $P \leq_{\mathfrak{m}} M$ of M we get the following implication

$$M_{i-1} \subseteq P \subseteq M_i \implies P = M_{i-1} \text{ or } P = M_i$$

If M admits a composition series $(M_0, M_1, \ldots, M_r)$ then M is said to be of *finite length*. And we will see in (3.117.(iii)) that in this case the length r of the series is uniquely determined. Hence this number will be called the **length** of the module M, denoted by

$$\ell(M) \;:=\; r \;\in\; \mathbb{N}$$

And in case M admits no (or no finite) composition series we say that M is of *infinite length* and we denote this situation, by writing

$$\ell(M) \;:=\; \infty$$

(3.116) Remark:

(i) If $\ell(M) = 0$ then $0 = M_0 = M$, that is M is the zero-module. And clearly if $M = 0$ is zero, then (0) is the only available composition series. Hence there is the equivalence

$$\ell(M) \;=\; 0 \quad\Longleftrightarrow\quad M \;=\; 0$$

(ii) If $\ell(M) = 0$ then $0 = M_0 \subset M_1 = M$ is a composition series, that is $M = M/0 = M_1/M_0$ is a simple R-module. Conversely if M is simple then $(0, M)$ already is the one and only composition series of M, such that

$$\ell(M) \;=\; 1 \quad\Longleftrightarrow\quad M \text{ is simple}$$

(iii) We will often use the following trick: If N is a simple R-module and $\iota : M \hookrightarrow N$ is an R-module monomorphism, then already $M = 0$ or $\iota : M \xrightarrow{\sim} N$ even is an isomorphism.

Prob let $Q := \mathrm{im}(\iota) \leq_{\mathsf{m}} N$ be the image of M in N. Then, as N is simple, we either have $Q = 0$ or $Q = N$. But as ι is injective $\mathrm{im}(\iota) = 0$ implies $M = \iota^{-1}(0) = 0$ and $\mathrm{im}(\iota) = N$ means that ι is surjective and hence an isomorphism $\iota : M \xrightarrow{\sim} N$.

(iv) Another trick is the following observation: If M is a simple R-module and $\varrho : M \twoheadrightarrow N$ is an R-module-epimorphism, then already $N = 0$ or $\varrho : M \xrightarrow{\sim} N$ even is an isomorphism.

Prob let $P := \mathrm{kn}(\varrho) \leq_{\mathsf{m}} M$ be the kernel of ϱ in M. Then, as M is simple, we either have $P = 0$ or $P = M$. But $\mathrm{kn}(\varrho) = 0$ implies that ϱ is injective (and hence an isomorphism $\varrho : M \xrightarrow{\sim} N$) and $\mathrm{kn}(\varrho) = M$ implies $N = \mathrm{im}(\varrho) = 0$.

(v) If V is a finite-dimensional vectorspace over some field E then the length of V is not a new invariant, it simply equals the the dimension of V, that is

$$\ell(V) \;=\; \dim(V)$$

Prob let $\{ v_1, \ldots, v_n \} \subseteq V$ be a basis of V, then we denote the subspaces $V_i := \mathrm{Lh}(v_1, \ldots, v_i)$ of V for $i \in 0 \ldots n$. Then we find $E \cong_{\mathsf{v}} V_i/V_{i-1} : a \mapsto av_i + V_{i-1}$ such that V_i/V_{i-1} is simple. Hence $(V_0, V_1, \ldots, V_n)$ is a composition series of V and in particular $\ell(V) = n$.

(vii) If V is a vector-space over the skew-field $(S,+,\cdot)$ and $x \in V$ is any non-zero element $x \neq 0$ of V. Then clearly $Sx \subseteq V$ is a simple sub-module of V. In particular V already is semi-simple. To see this simply choose a basis $B \subseteq V$ of V, then V can be decomposed, into

$$V \;=\; \bigoplus_{b \in V} Sb$$

(3.117) Theorem: (viz. 895) **Jordan-Hölder Theorem**
Let $(R,+,\cdot)$ be a commutative ring and M be an R-module of finite length $\ell(M) < \infty$ (that is M admits a composition series). Then we obtain the following statements

(i) If $P \;\leq_{\mathfrak{m}}\; M$ is a sub-module of M with $P \neq M$, then the length of M exceeds the length of P, formally that is

$$\ell(P) \;<\; \ell(M)$$

(ii) If M is an arbitrary R-module and $P \leq M$ is any sub-module of M then M has finite length if and only if both P and the quotient M/P are of finite length, formally that is

$$M \text{ has finite length} \quad\Longleftrightarrow\quad P \text{ and } M\Big/P \text{ have finite length}$$

And in this case we even obtain the following equality for the length of the modules involved

$$\ell(M) \;=\; \ell(P) + \ell\left(M\Big/P\right)$$

More generally, if $0 = P_0 \subseteq P_1 \subseteq P_2 \subseteq \ldots \subseteq P_n = M$ is an ascending chain of sub-modules of M, then we find the equality

$$\ell(M) \;=\; \sum_{k=1}^{n} \ell\left(P_k\Big/P_{k-1}\right)$$

(iii) Any two composition series of M are *equivalent*: That is, given any two composition series $(M_0, M_1, \ldots, M_r)$ and $(N_0, N_1, \ldots, N_s)$ of M, then we get $r = s$ and there is a permutation $\sigma \in S_r$ such that for any $i \in 1 \ldots r$ there is an isomorphy

$$M_i\Big/M_{i-1} \;\cong_{\mathfrak{m}}\; N_{\sigma(i)}\Big/N_{\sigma(i)-1}$$

(iv) Let us denote the set of all strictly increasing chains of sub-modules of M, that start in 0 and terminate in M by $\mathcal{C}(0,M)$, that is

$$\mathcal{C}(0,M) \;:=\; \left\{ (P_0, P_1, \ldots, P_r) \;\middle|\; \begin{array}{l} \forall\, i \in 0 \ldots r : P_i \;\leq_{\mathfrak{m}}\; M \\ 0 = P_0 \;\subset\; P_1 \;\subset\; \ldots \;\subset\; P_r = M \end{array} \right\}$$

Then we obtain a partial order $\leq$ on $\mathcal{C}(0,M)$ by virtue of the following definition: Given two chains $(P_0, P_1, \ldots, P_r)$ and $(Q_0, Q_1, \ldots, Q_s)$ we say that $(P_0, P_1, \ldots, P_r) \leq (Q_0, Q_1, \ldots, Q_s)$ iff $r \leq s$ and there is an injective map $\alpha : 0 \ldots r \hookrightarrow 0 \ldots s$ with $\alpha(0) < \alpha(1) < \cdots < \alpha(r)$ such that for any $i \in 0 \ldots r$ we get

$$P_i \;=\; Q_{\alpha(i)}$$

And thereby, if $(M_0, M_1, \ldots, M_r) \in \mathcal{C}(0, M)$ is a strictly increasing chain of sub-modules of M the following statements are equivalent

(a) $r = \ell(M)$

(b) $(M_0, M_1, \ldots, M_r)$ is maximal

(c) $(M_0, M_1, \ldots, M_r)$ is a composition series

(v) Any strictly increasing chain of sub-modules of M can be *refined* into a composition series: That is, if $P_0 \subset P_1 \subset \ldots \subset P_k$ is a strictly increasing chain of sub-modules $P_i \leq_{\mathsf{m}} M$, then there is a composition series $(M_0, M_1, \ldots, M_r)$ of M such that (in the sense of (iv) above) we get

$$(P_0, P_1, \ldots, P_k) \quad \leq \quad (M_0, M_1, \ldots, M_r)$$

(vi) Consider a finite chain of R-modules M_i where $i \in 0 \ldots n$ and homomorphisms $\varphi_i : M_{i-1} \to M_i$ for $i \in 1 \ldots n$. That is for any $i \in 2 \ldots n$ we have $\varphi_i \varphi_{i-1} = 0$

$$0 \xrightarrow{\varphi_0} M_0 \xrightarrow{\varphi_1} M_1 \xrightarrow{\varphi_2} \ldots \xrightarrow{\varphi_n} M_n \xrightarrow{\varphi_{n+1}} 0$$

Then we obtain: If for any $i \in 0 \ldots n$ the module M_i is of finite length and H_i denotes the i-th homology module $H_i := \mathsf{kn}(\varphi_{i+1})/\mathsf{im}(\varphi_i)$ then we get the equality

$$\sum_{i=0}^{n} (-1)^i \ell(M_i) \quad = \quad \sum_{i=0}^{n} (-1)^i \ell(H_i)$$

(3.118) Remark:
The theorem of Jordan-Hölder part (ii) has some easy to get, yet very noteworthy consequences: Let L, M and N be modules over some commutative ring $(R, +, \cdot)$ again then

(i) If $\varphi : M \twoheadrightarrow N$ is a surjective homomorphism and M has finite length, then N also has finite length and we find the upper bound

$$\ell(N) \quad \leq \quad \ell(M)$$

Prob Let $P := \mathsf{kn}(\varphi)$, then $N \cong_{\mathsf{m}} M/P$ by the first isomorphism theorem and hence N is of finite length and satisfies $\ell(M) = \ell(P) + \ell(N)$ according to (3.117.(ii))

(ii) If $0 \to L \to M \to N \to 0$ is a (short) exact chain of R-modules and L and M are of finite length, then the length of M is the sum of the lengths of L and N

$$\ell(M) \quad = \quad \ell(L) + \ell(N)$$

Prob Say $\varphi : L \to M$ and $\psi : M \to N$, as the chain is exact we have $L' := \mathsf{im}(\varphi) = \mathsf{kn}(\psi) \leq_{\mathsf{m}} M$. And as φ is injective $L \cong_{\mathsf{m}} L'$ and as ψ is surjective also $N = \mathsf{im}(\psi)$. Combining all this, we get $M/L' = M/\mathsf{kn}(\psi) \cong_{\mathsf{m}} \mathsf{im}(\psi) = N$ and hence find, by (3.117.(ii)) again

$$\ell(M) \;=\; \ell(L') + \ell\left(M \Big/ L'\right) \;=\; \ell(L) + \ell(N)$$

(iii) If both M and N are of finite length, then the length of $M \oplus N$ is the sum of those of M and N:

$$\ell(M \oplus N) \;=\; \ell(M) + \ell(N)$$

Prob We obtain a short exact chains of R-modules $0 \to M \to M \oplus N \to N \to 0$ by using the homomorphsims $\iota : M \hookrightarrow M \oplus N : x \mapsto (x,0)$ and $\pi : M \oplus N \twoheadrightarrow N : (x,y) \mapsto y$. So the equality of length is just a special case of (ii) above.

(iv) If $0 = M_0 \subseteq M_1 \subseteq \ldots \subseteq M_n = M$ is any increasing chain of sub-modules of M, then M has finite length, if and only if for any $k \in 1 \ldots n$ the quotient module M_k/M_{k-1} has finite length, and in this case the length of M is given to be

$$\ell(M) \;=\; \sum_{k=1}^{n} \ell\left(M_k \Big/ M_{k-1}\right)$$

Prob by induction on n: In case $n = 1$ we have $M = M/0 = M_1/M_0$. Now for the induction step: By (3.117.(ii)) M has finite length iff both M_{n-1} and $Q_n := M_n/M_{n-1}$ are of finite length and in this case we find $\ell(M) = \ell(M_{n-1}) + \ell(Q_n)$. If we now use the induction hypothesis on M_{n-1} we find the claim.

(3.119) Corollary: (viz. 901)
Let $(R,+,\cdot)$ be a commutative ring and M be an R-module, then we obtain the following statements

(i) M is noetherian, if and only if M is finitely generated and $R/\mathrm{ann}(M)$ is a noetherian ring, formally

$$M \text{ noetherian} \iff \mathrm{rank}(M) < \infty \text{ and } R \Big/ \mathrm{ann}(M) \text{ noetherian}$$

(ii) Under the assumption that M is finitely generated: M is artinian, if and only if $R/\mathrm{ann}(M)$ is an artinian ring, formally that is

$$M \text{ artinian} \iff R \Big/ \mathrm{ann}(M) \text{ artinian}$$

(iii) If M is a finitely generated, artinian R-module, then M already is an noetherian R-module, as well. Formally this is the implication

$$M \text{ artinian and finitely generated} \implies M \text{ noetherian}$$

(iv) If M is noetherian and $\varphi : M \to M$ is an R-module-endomorphism, then if φ is surjective, it already is bijective, that is the equivalence of

$$\varphi \text{ is surjective} \iff \varphi \text{ is bijective}$$

Nota in fact we have already proved this statement for any finitely generated module M over a general commutative ring R in (3.82). However the proof of the general case requires much more effort than the proof of this statement here.

(v) If M is artinian and $\varphi : M \to M$ is an R-module-endomorphism, then if φ is injective, it already is bijective, that is

$$\varphi \text{ is injective} \iff \varphi \text{ is bijective}$$

(vi) A module M is both artinian and noetherian, if and only if M is a module of finite length, formally

$$M \text{ artinian and noetherian} \iff \ell(M) < \infty$$

(vii) If R is an artinian ring, then the following 4 statements are equivalent

(a) M is artinian

(b) M is noetherian

(c) M is finitely generated

(d) M has finite length: $\ell(M) < \infty$

(viii) Let us now generalize proposition (3.113): If M is a semi-simple R-module (e.g. a vector space over a field), then the following 5 statements are equivalent:

(a) M is artinian

(b) M is noetherian

(c) M is finitely generated

(d) M has finite length: $\ell(M) < \infty$

(e) M is a finite direct sum of simple R-modules, that is there are finitely many ($i \in 1 \dots r$) simple sub-modules $M_i \leq_{\mathsf{m}} M$ of M such that $M = M_1 \oplus \cdots \oplus M_r$

M is finitely generated, iff $\operatorname{rank}(M) < \infty$, hence in case M even is a vector-space, that is R even is a field, we obtain the following sixth equivalent statement of (a) to (e) above:

(f) M is finite-dimensional: $\dim(M) < \infty$

(ix) Suppose M is a finitely generated R-module, such that every ascending chain of ideal-induced sub-modules of M stabilizes, then M is noetherian. That is: Suppose for every sequence of ideals $(\mathfrak{a}_k)$ where $\mathfrak{a}_k \trianglelefteq_{\mathsf{i}} R$ and $k \in \mathbb{N}$ that satisfies

$$\mathfrak{a}_0 M \subseteq \mathfrak{a}_1 M \subseteq \mathfrak{a}_2 M \subseteq \dots$$

there is some $s \in \mathbb{N}$ such that for any $i \in \mathbb{N}$ we get $\mathfrak{a}_{s+i} M = \mathfrak{a}_s M$, then M already is a noetherian R-module. The converse is true, as well, of course.

(3.120) Proposition: (viz. 909)
($\diamondsuit$) Let $(R, +, \cdot)$ be a commutative ring and L, M and N be R-modules, where L and M are artinian. Then the tensor product $L \otimes M$ is a module of finite length:

$$\ell\big(L \otimes M\big) < \infty$$

Let now $b : L \times M \to N$ be any bilinear map and pick up the notion of the *orthogonal complement* that will be introduced in (4.106), that is

$$\begin{aligned} L^{\top} &:= \{\, x \in M \mid \forall\, u \in L \,:\, b(u,x) = 0 \,\} \\ M^{\perp} &:= \{\, u \in L \mid \forall\, x \in M \,:\, b(u,x) = 0 \,\} \end{aligned}$$

If L and M are artinian, then the quotient modules $L/M^{\perp}$ and $M/L^{\top}$ are of finite length. In particular, if b is non-degenerate (i.e. $L^{\top} = 0$ and $M^{\perp} = 0$) then L and M are modules of finite length:

$$\ell\left(L \Big/ M^{\perp}\right) < \infty \quad \text{and} \quad \ell\left(M \Big/ L^{\top}\right) < \infty$$

3.12 Localization of Modules

We have already studied the localization of rings in section 2.10, now we would like to transfer this concept to modules. It turns out that the localization of modules combines neatly with the localization of rings. Also localization will preserve all the nice properites a module might have. Hence localization of modules is as powerful as the localization of rings and almost as useful.
Recall definition (2.113) which introduces the notion of a *multiplicatively closed* subset $U \subseteq R$ of a commutative ring $(R, +, \cdot)$. This is a subset U, such that $1 \in U$ and for any $u, v \in U$ we have $uv \in U$, as well. Also recall that a multiplicatively closed subset $U \subseteq R$ has been called *saturated* if $uv \in U$ implies $u \in U$ (and $v \in U$). We have already studied these sets in detail in section 2.10, so the reader is asked to refer to this section, in case of doubt. Let us now redo the construction of localization for modules in precisely the same manner, we used for rings:

(3.121) Definition: (viz. 1077)
Let $(R, +, \cdot)$ be any commutative ring, $U \subseteq R$ be a multiplicatively closed subset and M be an R-module. Then we obtain an equivalence relation $\sim$ on the set $U \times M$ by virtue of (with $x, y \in M$ and $u, v \in U$)

$$(u, x) \sim (v, y) \quad :\Longleftrightarrow \quad \exists\, w \in U \,:\, vwx = uwy$$

And we denote the quotient of $U \times M$ modulo $\sim$ by $U^{-1}M$ and the equivalence class of $(u, x) \in U \times M$ is denoted by x/u, formally we define

$$\begin{aligned} \frac{x}{u} &:= \{\, (v, y) \in U \times M \mid (u, x) \sim (v, y) \,\} \\ U^{-1}M &:= U \times M \Big/ \sim \end{aligned}$$

Now $U^{-1}M$ becomes an R-module again, even an $U^{-1}R$-module, under the following addition and scalar multiplications whith elements $a \in R$ and $a/u \in U^{-1}R$ respectively

$$\begin{aligned} \frac{x}{u} + \frac{y}{v} &:= \frac{vx + uy}{uv} \\ a\frac{x}{u} &:= \frac{ax}{u} \\ \frac{a}{u}\frac{y}{v} &:= \frac{ay}{uv} \end{aligned}$$

It is clear that under these operations the zero-element of $U^{-1}M$ is given to be $0/1$ and we obtain a canonical R-module homomorphism from M to $U^{-1}M$ by letting

$$\kappa \,:\, M \to U^{-1}M \,:\, x \mapsto \frac{x}{1}$$

In general this canonical homomorphism need not be and embedding (i.e. injective). Yet we do obtain the following implications for κ

$$\begin{aligned} U \subseteq \mathrm{NZD}_R(M) &\iff \kappa \text{ injective} \\ U \subseteq R^* &\implies \kappa \text{ bijective} \end{aligned}$$

(3.122) Remark: (viz. 1079)
The process of localization has already been commented on, in (2.117). However we would like to repeat some important properties of the localization. First of all x/u is zero, iff x can be annihilated by an element of U, that is

$$\frac{x}{u} = \frac{0}{1} \iff \exists\, w \in U : wx = 0$$

The next the important property is the cancellation of elements: Just as in the case of rings, the fractions x/u in $U^{-1}M$ can be reduced by common factors v of U. That is for any elements $x \in M$ and $u, v \in U$ we get the equality

$$\frac{vx}{vu} = \frac{x}{u}$$

And again this allows to express sums by going to a common denominator. That is consider $x_1, \ldots, x_n \in M$ and $u_1, \ldots, u_n \in U$. Then we denote $u := u_1 \ldots u_n \in U$ and $\widehat{u}_i := u/u_i \in U$ (e.g. $\widehat{u}_1 = u_2 \ldots u_n$). Then we have just noted that $x_i/u_i = (\widehat{u}_i x_i)/u$ and thereby

$$\frac{x_1}{u_1} + \cdots + \frac{x_n}{u_n} = \frac{\widehat{u}_1 x_1 + \cdots + \widehat{u}_n x_n}{u}$$

(3.123) Remark:
If $(R, +, \cdot)$ is a commutative ring, $U \subseteq R$ a multiplicatively closed set and A a commutative R-algebra, then the $U^{-1}R$-module $U^{-1}A$ also becomes an $U^{-1}R$-algebra, under the following multiplication

$$\cdot : U^{-1}A \times U^{-1}A \to U^{-1}A : \left(\frac{f}{u}, \frac{g}{u}\right) \mapsto \frac{fg}{uv}$$

Prob let us check that the multiplication is well-defined: Consider $f_1/u_1 = f_2/u_2$ and $g_1/v_1 = g_2/v_2$ and have to show $(f_1g_1)/(u_1v_1) = (f_2g_2)/(u_2v_2)$. By assumption there are some $p, q \in U$ such that $p\,u_2f_1 = p\,u_1f_2$ and $q\,v_2g_1 = q\,v_1g_2$. In particular $(pq)(u_2v_2)(f_1g_1) = (pu_2f_1)(qv_2g_1) = (pu_1f_2)(qv_1g_2) = (pq)(u_1v_1)f_2g_2$. But this is $(f_1g_1)/(u_1v_1) = (f_2g_2)/(u_2v_2)$. It is obvious, that this multiplication satisfies all the properties for $U^{-1}A$ to be an $U^{-1}R$-algebra. E.g. property (A) is just

$$\left(\frac{a}{w}\frac{f}{u}\right) \cdot \frac{g}{v} = \frac{(af) \cdot g}{w(uv)} = \frac{a(f \cdot g)}{w(uv)} = \frac{a}{w}\left(\frac{f}{u} \cdot \frac{g}{v}\right) = \frac{f \cdot (ag)}{u(wv)} = \frac{f}{u} \cdot \left(\frac{a}{w}\frac{g}{v}\right)$$

(3.124) Remark: (viz. 1079)
Let $(R, +, \cdot)$ be a commutative ring, $U \subseteq R$ be a multiplicatively closed set and let $S := U^{-1}R$. Now suppose M is an S-module already, then clearly M also is an R-module under the scalar multiplication

$$ax := \frac{a}{1}x$$

Let us emphasize this by writing M_R instead, if we consider M under this scalar multiplication with R. Under this construction we find:

(i) If we localize M_R in U we just find an isomorphic copy of M, to be explicit we have an isomorphism of S-modules the form

$$\kappa : M \xrightarrow{\sim} U^{-1}M_R : x \mapsto \frac{x}{1}$$

(ii) Also for any $u \in U$ we find that $\lambda_u : M_R \to M_R$ defined by scalar multiplication $\lambda_u(x) := ux$ is an automorphism of the R-module M_R.

(iii) And if N is another S-module and $\{ u/1 \mid u \in U \} \subseteq \text{NZD}_R(N)$ then a map $\varphi : M \to N$ is R-linear, if and only if it is S linear. In other words this is the equality

$$\text{mhom}(M_R, N_R) \quad = \quad \text{mhom}(M, N)$$

(3.125) Proposition: (viz. 1079)
Let $(R, +, \cdot)$ be a commutative ring $U \subseteq R$ be a multiplicatively closed set in R and let M be an R-module. Then the process of localization is compatible with sub-modules, homomorphsims, quotients and direct sums, in the following sense:

(i) If $P \leq_{\text{m}} M$ is an R-sub-module of M, then $U^{-1}P \leq_{\text{m}} U^{-1}M$ can be seen as an $U^{-1}R$-sub-module of $U^{-1}M$ canonically and we obtain the following isomorphy of $U^{-1}R$-modules

$$U^{-1}P \quad = \quad \left\{ \frac{x}{u} \mid x \in P, u \in U \right\} \quad \subseteq \quad U^{-1}M$$

$$U^{-1}\left(M \Big/ P \right) \quad \xrightarrow{\sim} \quad U^{-1}M \Big/ U^{-1}P \ : \ \frac{x+P}{u} \mapsto \frac{x}{u} + U^{-1}P$$

(ii) If N is another R-module and $\varphi : M \to N$ is a homomorphism of R-modules, then we obtain a homomorphism $U^{-1}\varphi$ of $U^{-1}R$-modules

$$U^{-1}\varphi \ : \ U^{-1}M \to U^{-1}N \ : \ \frac{x}{u} \mapsto \frac{\varphi(x)}{u}$$

And thereby $U^{-1}\varphi$ is injective, resp. surjective if and only if φ is injective, resp. surjective. In fact we even get the following identities

$$\begin{aligned} \text{kn}\left(U^{-1}\varphi \right) &= U^{-1}\text{kn}(\varphi) \\ \text{im}\left(U^{-1}\varphi \right) &= U^{-1}\text{im}(\varphi) \end{aligned}$$

(iii) If $I \neq \emptyset$ is an arbitrary index set and M_i is an R-module for any $i \in I$ then we obtain the following isomorphy of $U^{-1}R$-modules

$$\bigoplus_{i \in I} U^{-1}M_i \quad \xrightarrow{\sim} \quad U^{-1}\left(\bigoplus_{i \in I} M_i \right) \ : \ \left(\frac{x_i}{u_i} \right) \mapsto \frac{(\widehat{u}_i x_i)}{u}$$

Thereby u and $\widehat{u}_i$ are determined in the following way: Let $\Omega := \{ i \in I \mid x_i/u_i \neq 0/1 \}$ which is a finite set. In particular if I is finite itself we may simply take $\Omega = I$. Then $u := \prod_{i \in \Omega} u_i \in U$ is well-defined and for any $i \in I$ we let

$$\widehat{u}_i \quad := \quad \begin{cases} u/u_i \text{ if } i \in \Omega \\ \quad 1 \text{ if } i \notin \Omega \end{cases} \quad \in \quad U$$

(3.126) Remark: $(\diamondsuit)$
Suppose $(R,+,\cdot)$ is a commutative ring $U \subseteq R$ is multiplicatively closed and L, M and N are R-modules. If now $\varphi : L \to M$ and $\psi : M \to N$ are R-module homomorphisms then it is clear that

$$U^{-1}(\psi\psi) \;=\; (U^{-1}\psi)(U^{-1}\varphi)$$

As also $U^{-1}\mathbb{1} = \mathbb{1}$ this is a rather common situation that the more fancy language of category theory would put in the following way: The localization $M \mapsto U^{-1}M$ and $\varphi \mapsto U^{-1}\varphi$ is a covariant functor from the category of R-modules to the category of $U^{-1}R$-modules. Let us now regard a short exact sequence of R-modules, recall that the chain is said to be *exact* if at any position the image equals the kernel. In this case that is: φ is injective, ψ is surjective and $\mathrm{im}(\varphi) = \mathrm{kn}(\psi)$.

$$0 \to L \xrightarrow{\varphi} M \xrightarrow{\psi} N \to 0$$

Then the localization of this chain gives rise to the following short chain of $U^{-1}R$-modules. But then proposition (3.125.(ii)) implies that this localized chain is exact as well. In the fancy language of category theory again, that is: The localization functor $M \mapsto U^{-1}M$ and $\varphi \mapsto U^{-1}\varphi$ is *exact*.

$$0 \to U^{-1}L \xrightarrow{U^{-1}\varphi} U^{-1}M \xrightarrow{U^{-1}\psi} U^{-1}N \to 0$$

Prob as φ is injective, so is $U^{-1}\varphi$, since $\mathrm{kn}(U^{-1}\varphi) = U^{-1}\mathrm{kn}(\varphi) = U^{-1}0 = 0$. Likewise, as ψ is surjective, so is $U^{-1}\psi$, since $\mathrm{im}(U^{-1}\psi) = U^{-1}\mathrm{im}(\psi) = U^{-1}N$. And lastly we also find $\mathrm{im}(U^{-1}\varphi) = U^{-1}\mathrm{im}(\varphi) = U^{-1}\mathrm{kn}(\psi) = \mathrm{kn}(U^{-1}\psi)$. Altogether we found that the localized chain is exact again.

(3.127) Proposition: (viz. 1082)
Let $(R,+,\cdot)$ be a commutative ring and M be an R-module. If now $U \subseteq R$ is multiplicatively closed, then the sub-modules of the localization $U^{-1}M$ are selected from the sub-modules of M. That is we obtain an injective map

$$\overline{k} \;:\; \mathrm{Subm}_{U^{-1}R}(U^{-1}M) \hookrightarrow \mathrm{Subm}_R(M) \;:\; Z \mapsto \kappa^{-1}(Z)$$

$$\text{where} \quad \kappa^{-1}(Z) \;=\; \left\{ x \in M \mid \frac{x}{1} \in Z \right\}$$

This map $\overline{k}$ admits a left-inverse k (that is $k\overline{k} = \mathbb{1}$), that is surjective. And the left-inverse k is given by

$$k \;:\; \mathrm{Subm}_R(M) \twoheadrightarrow \mathrm{Subm}_{U^{-1}R}(U^{-1}M) \;:\; P \mapsto U^{-1}P$$

$$\text{where} \quad U^{-1}P \;=\; \left\{ \frac{x}{u} \mid x \in P \text{ and } u \in U \right\}$$

Thereby we generally get $P \subseteq \overline{k}k(P) = \{\, x \in M \mid \exists\, u \in U \,:\, ux \in P \,\}$ for any R-sub-module $P \leq_{\mathrm{m}} M$. And the converse inclusion is true if and only if P is pure, concerning elements the of U, this is to say

$$\overline{k}k(P) = P \quad\Longleftrightarrow\quad \forall\, x \in M \;\forall\, u \in U \,:\, ux \in P \implies x \in P$$

Both of these maps k and $\overline{k}$ are order preserving and respect intersections. That is for any sub-modules $P, Q \leq_{\mathsf{m}} M$ and $Y, Z, Z_i \leq_{\mathsf{m}} U^{-1}M$ we get

$$\begin{aligned} P \subseteq Q &\implies k(P) \subseteq k(Q) \\ Y \subseteq Z &\implies \overline{k}(Y) \subseteq \overline{k}(Z) \\ k(P \cap Q) &= k(P) \cap k(Q) \\ \overline{k}\left(\bigcap_{i\in I} Z_i\right) &= \bigcap_{i\in I} \overline{k}(Z_i) \end{aligned}$$

In particular, if we generalize k to arbitrary subsets $X \subseteq M$, i.e. for $k(X) := \{ x/u \mid x \in X, u \in U \}$, then we get the following equality of the sub-modules generated by X

$$\mathsf{Lh}_{U^{-1}R}\Big(k(X)\Big) = k\Big(\mathsf{Lh}_R(X)\Big)$$

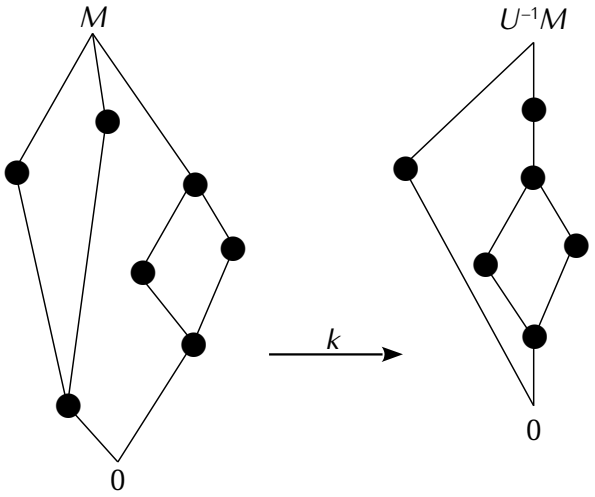
(3.128) Remark:
It is clear that any $U^{-1}R$-sub-module of $U^{-1}M$ already is an R-sub-module of $U^{-1}M$. But the converse need not be true! That is an R-sub-module need not be an $U^{-1}R$-sub-module of $U^{-1}M$ and hence

$$\mathsf{Subm}_{U^{-1}R}(U^{-1}M) \subset \mathsf{Subm}_R(U^{-1}M)$$

As an example regard the localization $\mathbb{Z}$ in $2\mathbb{Z}$, that is we regard the $\mathbb{Z}$-module $\mathbb{Z}_{(2)} = (\mathbb{Z} \setminus 2\mathbb{Z})^{-1}\mathbb{Z}$ and consider it as a sub-module of $\mathbb{Z}_{(2)} = \{ a/2^k \mid a \in \mathbb{Z}, k \in \mathbb{N} \} \subseteq \mathbb{Q}$. Then it is clear that $\mathbb{Z} \subseteq \mathbb{Z}_{(2)}$ is an $\mathbb{Z}$-sub-module, but not an $\mathbb{Z}_{(2)}$-sub-module, as it is not an ideal.

Prob if Z is an $U^{-1}R$-sub-module then for any $x/u \in Z$ and any $a \in R$ we already get $a(x/u) = (ax)/u = (a/1)(x/u) \in Z$ again, hence the inclusion of sub-modules. And that $\mathbb{Z}$ is a $\mathbb{Z}$-sub-module of $\mathbb{Z}_{(2)}$ is clear (it is a commutative group under the addition), but it is not an ideal, since $(1/2)3 = 3/2 \notin \mathbb{Z}$.

(3.129) Remark:
Of course we could also generalize $\overline{k}$ to arbitrary subsets $W \subseteq U^{-1}M$, that is we could also denote $\overline{k}(W) := \{ x \in M \mid x/1 \in W \}$. However, $\overline{k}$ does not respect the generation of sub-modules, that is for an arbitrary subset $W \subseteq U^{-1}M$ it may occur that we only get one inclusion



$$\mathsf{Lh}_R\Big(\overline{k}(W)\Big) \subset \overline{k}\Big(\mathsf{Lh}_{U^{-1}R}(W)\Big)$$

Prob let us first prove the inclusion "$\subseteq$": If $x \in \mathsf{Lh}_R(\overline{k}(W))$, then x is of the form $x = \sum_i a_i x_i$ where $x_i/1 \in W$. And we need to show that $x/1 \in \mathsf{Lh}_{U^{-1}R}(W)$ again. But this is easy, since

$$\frac{x}{1} = \sum_{i=1}^{n} \frac{a_i x_i}{1} = \sum_{i=1}^{n} \frac{a_i}{1}\frac{x_i}{1} \in \mathsf{Lh}_{U^{-1}R}(W)$$

As a counter-example to the equality regard $\mathbb{Z}_{(2)}$ again. If $W = \{ 1/2 \} \subseteq \mathbb{Z}_{(2)}$ then $\overline{k}(W)$ is empty, as $\overline{k}(W) = \{ x \in \mathbb{Z} \mid 2x = 1 \} = \emptyset$. Hence $\overline{k}(W)$ generates the sub-module $0 \leq_{\mathsf{m}} \mathbb{Z}$ of $\mathbb{Z}$. However W generates the entire $\mathbb{Z}_{(2)}$ as an $\mathbb{Z}_{(2)}$-sub-module. Hence $\overline{k}(\mathsf{Lh}_{\mathbb{Z}_{(2)}}(W)) = \overline{k}(\mathbb{Z}_{(2)}) = \mathbb{Z}$.

(3.130) Remark:
The following figure is supposed to enlighten the situation of the structure of sub-modules of $U^{-1}M$ a little: k is surjective, respects the inclusion and finite intersections. However if U contains an annihilator of P then $U^{-1}P = 0$ vanishes and hence it may well be the the structure of sub-modules will be reduced. Thus it may well occur that we get the following structure of sub-modules, where every sub-module is depicted as a $\bullet$:

(3.131) Corollary: (viz. 1096)
Let $(R, +, \cdot)$ be a commutative ring, $U \subseteq R$ be a multiplicatively closed subset and consider an R-module M. Regarding the localization $U^{-1}M$ as an $U^{-1}R$-module we get the following properties:

(i) If the set $\{ m_i \mid i \in I \} \subseteq M$ generates M as an R-module, then the set $\{ m_i/1 \mid i \in I \} \subseteq U^{-1}M$ generates $U^{-1}M$ as an $U^{-1}R$-module.

(ii) If the set $\{ m_i \mid i \in I \} \subseteq M$ is R-linearly independent, then the set $\{ m_i/1 \mid i \in I \} \subseteq U^{-1}M$ is $U^{-1}R$-linearly independent.

(iii) Consequentially: If the set $\{ m_i \mid i \in I \} \subseteq M$ is an R-basis of M, then $\{ m_i/1 \mid i \in I \} \subseteq U^{-1}M$ is an $U^{-1}R$-basis of $U^{-1}M$, as well.

(iv) If we abbreviate by $\star$ any one of the words *finitely generated*, *free*, *noetherian*, *artinian* or *injective*, then we get the following implication:

$$M \text{ is } \star \ R\text{-module} \quad \Longrightarrow \quad U^{-1}M \text{ is a } \star \ U^{-1}R\text{-module}$$

(3.132) Lemma: (viz. 1085) **Universal Property**
Let $(R, +, \cdot)$ and $(S, +, \cdot)$ be commutative rings, $U \subseteq R$ be multiplicatively closed and $\alpha : R \to S$ be a homomorphism of rings, such that $\alpha(U) \subseteq S^*$. Further consider an R-module M and an S-module N. Then N can be turned into both, an R and an $U^{-1}R$-module under the following scalar multiplications

$$R \times N \to N \ : \ (a, y) \mapsto ay := \alpha(a)y$$

$$U^{-1}R \times N \to N \ : \ (a/u, y) \mapsto \frac{a}{u}y := \alpha(u)^{-1}\alpha(a)y$$

If now $\varphi : M \to N$ is any R-module homomorphism, then there is a uniquely determined $U^{-1}R$-module homomorphism $\overline{\varphi} : U^{-1}M \to N$ such that $\varphi = \overline{\varphi}\kappa$. And this is given to be the following

$$\overline{\varphi} \ : \ U^{-1}M \to N \ : \ \frac{x}{u} \mapsto \alpha(u)^{-1}\varphi(x)$$

(3.133) Corollary: (viz. 1098)
Let $(R, +, \cdot)$ be any commutative ring and $U \subseteq R$ be multiplicatively closed. If further M and N are R-modules then the set $\mathrm{mhom}_R(M, N)$ of R-module homomorphisms from M to N is an R-module itself under the point-wise operations $(\varphi + \psi)(x) := \varphi(x) + \psi(x)$ and $(a\varphi)(x) := a\varphi(x)$. Hence we can even localize $\mathrm{mhom}_R(M, N)$ and thereby find the following homomorphism of R-modules

$$h \ : \ U^{-1}\mathrm{mhom}_R(M, N) \to \mathrm{mhom}_{U^{-1}R}(U^{-1}M, U^{-1}N) \ : \ \frac{\varphi}{u} \mapsto \frac{U^{-1}\varphi}{u}$$

Thereby $U^{-1}\varphi/u : U^{-1}M \to U^{-1}N$ is defined by $U^{-1}\varphi/u : x/v \mapsto \varphi(x)/uv$. And this homomorphism h even satisfies the following two additional properties:

(i) If M is finitely generated then h is injective.

(ii) If M admits a finite free presentation, then h is bijective. Nota a finite, free presentation of M is an exact chain of R-module homomorphisms of the form (where $m, n \in \mathbb{N}$)

$$R^m \xrightarrow{\alpha} R^n \xrightarrow{\omega} M \to 0$$

(3.134) Definition:
If $(R, +, \cdot)$ is a commutative ring and $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ is a prime ideal, then $R \setminus \mathfrak{p}$ is a multiplicatively closed (even saturated) set. Hence if M is an R-module we can define the localization of M with respect to this set. We will denote this localization by

$$M_{\mathfrak{p}} \ := \ (R \setminus \mathfrak{p})^{-1}M$$

Likewise if M and N are R-modules and $\varphi : M \to N$ is a homomorphism of R-modules, then we can localize φ as explained in (3.125.(ii))

$$\varphi_{\mathfrak{p}} \ : \ U^{-1}M \to U^{-1}N \ : \ \frac{x}{u} \mapsto \frac{\varphi(x)}{u}$$

(3.135) Lemma: (viz. 1097)
If $(R, +, \cdot)$ is any non-zero $R \neq 0$, commutative ring and M is an R-module, then the following three statements are equivalent

(a) $M = 0$

(b) $\forall\, \mathfrak{p} \in \mathrm{Spec}(R)$ we get $M_{\mathfrak{p}} = 0$

(c) $\forall\, \mathfrak{m} \in \mathrm{Smax}(R)$ we get $M_{\mathfrak{m}} = 0$

(3.136) Corollary: (viz. 1098)
If $(R,+,\cdot)$ is any non-zero $R \neq 0$, commutative ring, M is any R-module, $x \in M$ and $P \leq_{\mathfrak{m}} M$ is a sub-module of M. Then we get the equivaleny

$$x \in P \iff \forall\, \mathfrak{m} \in \mathrm{Smax}(R) \,:\, \frac{x}{1} \in P_{\mathfrak{m}}$$

(3.137) Corollary: (viz. 1098)
Let $(R,+,\cdot)$ be any non-zero $R \neq 0$, commutative ring, M and N be any R-modules and $\varphi : M \to N$ be an R-module homomorphism. If we now abbreviate by $\star$ any one of the words *injective*, *surjective*, *bijective* or *zero* (i.e. the zero homomorphism $x \mapsto 0$), then we obtain the following equivalences

(a) φ is $\star$

(b) $\forall\, \mathfrak{p} \in \mathrm{Spec}(R)$ we get $\varphi_{\mathfrak{p}}$ is $\star$

(c) $\forall\, \mathfrak{m} \in \mathrm{Smax}(R)$ we get $\varphi_{\mathfrak{m}} = 0$ is $\star$

(3.138) Definition:
Let $(R,+,\cdot)$ be a commutative ring and M be an R-module, then we define the **support** of M to be the collection of prime ideals $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$ such that $M_{\mathfrak{p}} \neq 0$ is not the zero-module, that is

$$\mathrm{Supp}(M) \;:=\; \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid M_{\mathfrak{p}} \neq 0 \,\}$$

Remark: Note that by construction $M_{\mathfrak{p}} = 0$ is equivalent, to the following property: For any $x \in M$ there is some $u \in R \setminus \mathfrak{p}$ such that $ux = 0$. We will give equivalent constructions in (5.7.(iii)).

(3.139) Proposition: (viz. 1149)
Let $(R,+,\cdot)$ be a commutative ring, M and N be R-modules and consider $P \leq_{\mathfrak{m}} M$ a sub-module of M. Then we have the following statements

(i) The zero-module is the one and only R-module with empty support. That is we find the equivalence

$$M = 0 \iff \mathrm{Supp}(M) = \emptyset$$

(ii) There is an injective homomorphism of R-modules from M into the direct sum of the $M_{\mathfrak{p}}$ where $\mathfrak{p} \in \mathrm{Supp}(M)$ runs along the prime ideals of $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$, that support M, given by

$$M \hookrightarrow \bigoplus_{\mathfrak{p} \in \mathrm{Supp}(M)} M_{\mathfrak{p}} \;:\; x \mapsto \left(\frac{x}{1}\right)$$

(iii) Recall the notation $\mathbb{V}(\mathfrak{a}) := \{\, \mathfrak{p} \subseteq \mathrm{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p} \,\}$ for some ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$. If we regard $R/\mathfrak{a}$ as an R-module, then this equals the support of $R/\mathfrak{a}$

$$\mathrm{Supp}\left(R \Big/ \mathfrak{a}\right) \;=\; \mathbb{V}(\mathfrak{a})$$

(iv) Together the support of P and M/P build up the support of M, i.e. we find the following equality

$$\mathrm{Supp}(M) \;=\; \mathrm{Supp}(P) \cup \mathrm{Supp}\left(M \Big/ P\right)$$

More generally: If $0 \to L \to M \to N \to 0$ is a short exact chain of R-modules then the support of M combines the supports of both L and N, in formal terms

$$\mathrm{Supp}(M) \;=\; \mathrm{Supp}(L) \cup \mathrm{Supp}(N)$$

(v) Suppose $I \neq \emptyset$ is a non-empty index set and for any $i \in I$ we have a sub-module $P_i \leq_{\mathfrak{m}} M$. Then the support of the sum of the P_i is the union of the supports of the P_i, that is

$$\mathrm{Supp}\left(\sum_{i\in I} P_i\right) \;=\; \bigcup_{i\in I} \mathrm{Supp}(P_i)$$

(vi) If $M = \mathrm{Lh}\{\, m_i \mid i \in I \,\}$ (where $I \neq \emptyset$) and $\mathfrak{a}_i := \mathrm{ann}(m_i)$ is the annihilator of the element m_i then the support of M is given to be

$$\mathrm{Supp}(M) \;=\; \bigcup_{i\in I} \mathbb{V}(\mathfrak{a}_i)$$

In particular if M is finitely generated, then the support of M is the set of prime ideals of R that contain the annihilator of M

$$\mathrm{Supp}(M) \;=\; \mathbb{V}\big(\mathrm{ann}(M)\big)$$

More generally: If M is finitely generated and $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ is an ideal of R, then the support of the R-module $M/\mathfrak{a}M$ is given to be

$$\mathrm{Supp}\left(M\big/_{\mathfrak{a}M}\right) \;=\; \mathbb{V}(\mathfrak{a}) \cap \mathbb{V}\big(\mathrm{ann}(M)\big) \;=\; \mathbb{V}\big(\mathfrak{a} + \mathrm{ann}(M)\big)$$

(vii) If M is finitely generated, then $a \in R$ is contained in all $\mathfrak{p} \in \mathrm{Supp}(M)$ if and only if the endomorphism $M \to M : x \mapsto ax$ is nilpotent. More explicitly this reads as

$$\bigcap \mathrm{Supp}(M) \;=\; \{\, a \in R \mid \exists\, n \in \mathbb{N} \,:\, a^n M = 0 \,\}$$

Now let $\mathfrak{a} \in R$ be an ideal of R, such that both M and $\mathfrak{a}$ are finitely generated. Then we find the following equivalence

$$\mathrm{Supp}(M) \;\subseteq\; \mathbb{V}(\mathfrak{a}) \quad\Longleftrightarrow\quad \exists\, n \in \mathbb{N} \,:\, \mathfrak{a}^n M = 0$$

(viii) $(\diamondsuit)$ If M and N are finitely generated, then the support of the tensor product $M \otimes N$ consists of those prime ideals $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$, that support both M and N, that is

$$\mathrm{Supp}(M \otimes N) \;=\; \mathrm{Supp}(M) \cap \mathrm{Supp}(N)$$

In particular if both, M and N are finitely generated, then the tensor product $M \otimes N$ is zero if and only if there are a and $b \in R$, such that $a + b = 1$, $ax = 0$ for any $x \in M$ and $by = 0$ for any $y \in N$. In compact form this reads, as

$$M \otimes N \;=\; 0 \quad\Longleftrightarrow\quad \mathrm{ann}(M) + \mathrm{ann}(N) \;=\; R$$

3.13 Tensor Products

Consider some arbitrary, but non-empty, sets M_1, M_2 to M_n and denote their cartesian product by $X := M_1 \times \cdots \times M_n$. That is X consists of all n-tuples $(x_1, \ldots, x_n)$ where $x_j \in M_j$, formally

$$X \;=\; \{\, (x_1, \ldots, x_n) \mid \forall\, j \in 1 \ldots n \,:\, x_j \in M_j \,\}$$

And as all the M_j have been non-empty, so is X. Therefore, for any commutative ring $(R, +, \cdot)$, we can take a look at the free module $R^{\oplus X}$ generated by X over R. By definition this module consists of all sequences $a = (a_x) \in R^X$ indexed by $x \in X$, such that $a_x = 0$ for all but finitely many $x \in X$

$$R^{\oplus X} \;=\; \{\, a : X \to R : x \mapsto a_x \;\mid\; \#\{\, x \in X \mid a_x \neq 0 \,\} < \infty \,\}$$

As usual we write (a_x) instead of $a : x \mapsto a_x$ and take the addition and scalar-multiplication of $R^{\oplus X}$ to be point-wise: That is $b(a_x) = (ba_x)$ and $(a_x) + (b_x) = (a_x + b_x)$. And thereby we obtain the standard (Euclidean) basis $\{\, e_x \mid x \in X \,\}$ where $e_x : y \mapsto \delta_{x,y}$. That is $e_x : X \to R$ is the sequence with $e_x : x \mapsto 1$ and $e_x : y \mapsto 0$ for any other $y \neq x$. It stands to reason to identify $x \in X$ with e_x, i.e. we rewrite

$$\sum_{x \in X} a_x x \;:=\; \sum_{x \in X} a_x e_x \;=\; (a_x)$$

Note that this sum is well-defined, as $a_x = 0$ for all but *finitely* many $x \in X$. Using this notation the point-wise operations on $R^{\oplus X}$ take a particularly neat form

$$\begin{aligned} b \sum_{x \in X} a_x x \;&:=\; \sum_{x \in X} (b\, a_x) x \\ \sum_{x \in X} a_x x + \sum_{x \in X} b_x x \;&:=\; \sum_{x \in X} (b_x + a_x) x \end{aligned}$$

But what happens if the M_j are R-modules again, not only sets? The answer is rather deflating: Just nothing! Of course (for any $a \in R$ and any $x_i \in M_i$) the element $(ax_1, x_2, \ldots, x_n)$ is contained in $R^{\oplus X}$, but is has absolutely nothing to do with $a(x_1, x_2, \ldots, x_n)$. So in order to make the operations of $R^{\oplus X}$ compatible with the operations of the M_j we need to make certain identifications. To be precise we would like to have (for any $i \in 1 \ldots n$)

$$\begin{aligned} [x_1, \ldots, ax_i, \ldots, x_n] \;&=\; a\,[x_1, \ldots, x_i, \ldots, x_n] \\ [x_1, \ldots, x_i + y_i, \ldots, x_n] \;&=\; [x_1, \ldots, x_i, \ldots, x_n] + [x_1, \ldots, y_i, \ldots, x_n] \end{aligned}$$

where $[x_1, \ldots, x_n]$ denotes a suitable equivalence class of $(x_1, \ldots, x_n)$. This is the idea behind the following construction, so this is a completely natural thing to do. Thereby the equivalence class $[x_1, \ldots, x_n]$ will be $x_1 \otimes \ldots \otimes x_n$. However it is commonplace that - seeing this for the first time - this construction seems to be a little weird. The elements of $M_1 \otimes \ldots \otimes M_n$ are rather cumbersome to handle. In this sense the internal structure of $M_1 \otimes \ldots \otimes M_n$ worsens. But on the positive side the external structure of $M_1 \otimes \ldots \otimes M_n$ (i.e. how it interacts with other modules or constructions, like direct sums, localizations or homomorphisms) is extremely well-behaved. And this is precisely the reason, that gives this construction its powerful punch.

(3.140) Definition:
Let $(R,+,\cdot)$ be any commutative ring and consider some R-modules M_1 to M_n (where $1 \leq n \in \mathbb{N}$). First of all we take the cartesian product of the M_j as an index set, denoted by

$$X \;=\; M_1 \times \cdots \times M_n$$

Then we take to the free R-module $R^{\oplus X}$ generated by X over R and denote its Euclidean basis by $\{\, e_x \mid x \in X \,\}$, where $e_x : y \mapsto \delta_{x,y}$. Let us finally (for any $i \in 1 \ldots n$, $x = (x_1, \ldots, x_n) \in X$, $a \in R$ and $y_i \in M_i$) denote the following elements of $R^{\oplus X}$

$$\begin{aligned} s(i,x,a) &= a e_{(x_1,\ldots,x_i,\ldots,x_n)} - e_{(x_1,\ldots,ax_i,\ldots,x_n)} \\ a(i,x,y_i) &= e_{(x_1,\ldots,x_i,\ldots,x_n)} + e_{(x_1,\ldots,y_i,\ldots,x_n)} - e_{(x_1,\ldots,x_i+y_i,\ldots,x_n)} \end{aligned}$$

Then we denote the sub-module of $R^{\oplus X}$ generated by all these elements $s(i,x,a)$ and $a(i,x,y_i)$ by T

$$\begin{aligned} T \;:=\; & \mathrm{Lh}_R\{\, s(i,x,a) \mid i \in 1 \ldots n,\, x \in X,\, a \in R \,\} + \\ & \mathrm{Lh}_R\{\, a(i,x,y_i) \mid i \in 1 \ldots n,\, x \in X,\, y_i \in M_i \,\} \end{aligned}$$

Then we can finally define the **tensor product** $M_1 \otimes \ldots \otimes M_n$ of the M_j to be the quotient module of $R^{\oplus X}$ modulo this sub-module T. Also we define the **tensor product** $x_1 \otimes \ldots \otimes x_n$ of the elements $x_j \in M_j$ to be the equivalence class of $e_{(x_1,\ldots,x_n)}$, as an element of $M_1 \otimes \ldots \otimes M_n$

$$\begin{aligned} M_1 \otimes \ldots \otimes M_n &:= R^{\oplus X} \big/ T \\ x_1 \otimes \ldots \otimes x_n &:= e_{(x_1,\ldots,x_n)} + T \end{aligned}$$

(3.141) Remark:

(i) Let us explicitly give the generators of the sub-module T in case $n = 2$: The tensor product $M_1 \otimes M_2$ is the quotient of the free module $R^{\oplus(M_1 \times M_2)}$ by the sub-module T that is generated by the following elements, where x_1 and $y_1 \in M_1$ and x_2 and $y_2 \in M_2$ and $a \in R$

$$\begin{aligned} a e_{(x_1,x_2)} - e_{(ax_1,x_2)} \\ a e_{(x_1,x_2)} - e_{(x_1,ax_2)} \\ e_{(x_1,x_2)} + e_{(y_1,x_2)} - e_{(x_1+y_1,x_2)} \\ e_{(x_1,x_2)} + e_{(x_1,y_2)} - e_{(x_1,x_2+y_2)} \end{aligned}$$

(ii) By definition of the elements $s(i,x,a)$ and $a(i,x,y_i)$ it is clear that we get the following relations between these and the basis elements of $R^{\oplus X}$

$$\begin{aligned} e_{(x_1,\ldots,ax_i,\ldots,x_n)} + s(i,x,a) &= a e_{(x_1,\ldots,x_i,\ldots,x_n)} \\ e_{(x_1,\ldots,x_i+y_i,\ldots,x_n)} + a(i,x,y_i) &= e_{(x_1,\ldots,x_i,\ldots,x_n)} + e_{(x_1,\ldots,y_i,\ldots,x_n)} \end{aligned}$$

And as both $s(i,x,a)$ and $a(i,x,y_i)$ are contained in T they are eliminated when going to to the quotient. That is we immediately find the following relations in the tensor product $M_1 \otimes \ldots \otimes M_n$

$$\begin{aligned} x_1 \otimes \ldots \otimes (ax_i) \otimes \ldots \otimes x_n &= a(x_1 \otimes \ldots \otimes x_i \otimes \ldots \otimes x_n) \\ x_1 \otimes \ldots \otimes (x_i + y_i) \otimes \ldots \otimes x_n &= (x_1 \otimes \ldots \otimes x_i \otimes \ldots \otimes x_n) + \\ & \quad (x_1 \otimes \ldots \otimes y_i \otimes \ldots \otimes x_n) \end{aligned}$$

And this of course is precisely the reason for the construction of the tensor product. For more comments on our reasoning also refer to the introduction to this section. In other words these relations are nothing but the R-multi-linearity of the following map

$$\begin{aligned} \tau &: M_1 \times \cdots \times M_n \to M_1 \otimes \ldots \otimes M_n \\ &: (x_1, \ldots, x_n) \mapsto x_1 \otimes \ldots \otimes x_n \end{aligned}$$

(ii) Note that the first relation has a rather drastic consequence: If any element x_i of the tensor product $x_1 \otimes \ldots \otimes x_n$ is zero, then the entire tensor is zero

$$x_1 \otimes \ldots \otimes 0 \otimes \ldots \otimes x_n = 0 \otimes \ldots \otimes 0 \otimes \ldots \otimes 0 = 0$$

This is clear, as $0 \in M_i$ allows to pull $0 \in R$ out, annihilating the entire element $x_1 \otimes \ldots \otimes x_n$. This is the reason why we speak of the tensor *product*, in contrast to the direct *sum*, where a single zero does not annihilate the entire tuple $(x_1, \ldots, x_n)$. For more details on this refer to (3.154.(i)).

(iii) The converse need not be true, however. For example consider $1 \otimes 1 \in \mathbb{Z}_3 \otimes \mathbb{Z}_5$, then we have $1 \otimes 1 = 1 \otimes 6 = 3 \otimes 2 = 0 \otimes 2 = 0$. That is $x \otimes y = 0$ does *not* imply $x = 0$ or $y = 0$. In fact we have just seen, that the entire tensor product $\mathbb{Z}_3 \otimes \mathbb{Z}_5 = 0$ vanishes!

(iv) As the e_x generate $R^{\oplus X}$ (they even form an R-basis) it is clear that the elements $x_1 \otimes \ldots \otimes x_n$ generate the tensor product $M_1 \otimes \ldots \otimes M_n$. That is every element of the tensor-product can be written (in a non-unique way!) as (for some $a_k \in R$ and $x_{i,k} \in M_i$)

$$\sum_{k=1}^{m} a_k (x_{1,k} \otimes \ldots \otimes x_{n,k})$$

(v) Consider any tensor $t \in M_1 \otimes \ldots \otimes M_n$ then we define the **rank** $\mu(t)$ of t to be the minimal number of *pure* tensors $x_{1,k} \otimes \ldots \otimes x_{n,k}$ which are required to build up t

$$\mu(t) := \min \left\{ m \in \mathbb{N} \;\middle|\; \begin{array}{l} \exists\, a_k \in R \\ \exists\, x_{i,k} \in M_k \end{array} : t = \sum_{k=1}^{m} a_k\, x_{1,k} \otimes \ldots \otimes x_{n,k} \right\}$$

(vi) On some rare occasions we use more than one ring R. In this case we emphasize the ring R used for the construction (that is R in the free module $R^{\oplus X}$) of the tensor product, by writing

$$M_1 \otimes_R \ldots \otimes_R M_n := M_1 \otimes \ldots \otimes M_n$$

(vii) For simplicities sake we have used a commutative base ring R here. However it is possible to define the tensor product over non-commutative rings, as well. The complication is, in case of non-commutative rings the scalar multiplication from the right yields a different result. Hence in this case one has to introduce the notion of *R-S-bimodules* first, an approach followed e.g. in the highly recommended textbook of [Adkins, Weintraub, Algebra, GTM 136].

Let us now consider the R-modules M_1 to M_n over a fixed commutative ring $(R, +, \cdot)$ again. If now N is another R-module, then recall that a map $\varphi : M_1 \times \cdots \times M_n \to N$ has been said to be *R-multilinear*, iff for any $i \in 1 \dots n$ and any fixed $x_j \in M_j$ [where $i \neq j \in 1 \dots n$] the maps

$$M_i \to N \ : \ x_i \mapsto \varphi(x_1, \dots, x_i, \dots, x_n)$$

are R-linear (that is homomorphisms of R-modules) - see the end of section 3.8 for a more detailed definition of this notion. And as we have seen in the remark above that the map

$$\tau \ : \ M_1 \times \cdots \times M_n \to M_1 \otimes \dots \otimes M_n \ : \ (x_1, \dots, x_n) \mapsto x_1 \otimes \dots \otimes x_n$$

is R-multilinear. In fact if φ is *any* R-multilinear map, as above, then φ already factors through τ, that is $\varphi = \overline{\varphi}\tau$ for some R-linear map $\overline{\varphi}$. This is the so-called *universal property* of the tensor product:

(3.142) Lemma: (viz. 1118)
Let $(R, +, \cdot)$ be any commutative ring and consider the R-modules M_1 to M_n (where $1 \leq n \in \mathbb{N}$) and N. If now φ is any R-multilinear map

$$\varphi \ : \ M_1 \times \cdots \times M_n \to N$$

then φ factors through $\tau : (x_1, \dots, x_n) \mapsto x_1 \otimes \dots \otimes x_n$, that is there is a uniquely determined R-linear map $\overline{\varphi}$ such that $\varphi = \overline{\varphi}\tau$ and thereby

$$\begin{aligned} \overline{\varphi} \ &: \ M_1 \otimes \dots \otimes M_n \to N \\ &: \ \sum_{i=1}^{k} a_i (x_{i,1} \otimes \dots \otimes x_{i,n}) \mapsto \sum_{i=1}^{k} a_i \varphi(x_{i,1}, \dots, x_{i,n}) \end{aligned}$$

Thereby the map $\varphi \mapsto \overline{\varphi}$ is an isomorphism of R-modules from the R-multilinear maps on $M_1 \times \cdots \times M_n$ to the R-linear maps on $M_1 \otimes \dots \otimes M_n$

$$\mathrm{mult}_R(M_1 \times \cdots \times M_n, N) \ \xrightarrow{\sim} \ \mathrm{mhom}_R(M_1 \otimes \dots \otimes M_n, N) \ : \ \varphi \mapsto \overline{\varphi}$$

(3.143) Remark:
Let R be a commutative ring and L, M and N be R-modules again. Note that a map $\varphi : L \times M \to N$ is bilinear if and only if its stepwise iteration $L \to \mathrm{mhom}(M, N) : \ell \mapsto (m \mapsto \varphi(\ell, m))$ is linear. Hence we can identify the multi-linear maps $L \times M \to N$ with $\mathrm{mhom}(L, \mathrm{mhom}(M, N))$ and thereby find the following isomorphies of R-modules

$$\begin{array}{rcl} \mathrm{mhom}(L \otimes M, N) & \xrightarrow{\sim} & \mathrm{mhom}(L, \mathrm{mhom}(M, N)) \\ \varphi & \mapsto & (\ell \mapsto (m \mapsto \varphi(\ell \otimes m))) \\ \mathrm{mhom}(L \otimes M, N) & \xrightarrow{\sim} & \mathrm{mhom}(M, \mathrm{mhom}(L, N)) \\ \varphi & \mapsto & (m \mapsto (\ell \mapsto \varphi(\ell \otimes m))) \end{array}$$

(3.144) Corollary: (viz. 1119)
Let $(R, +, \cdot)$ be a commutative ring and M_1 to M_n be R-modules. Then the tensor product of these modules is associative and commutative up to isomorphy. That is we get the following isomorphies:

(i) If $\sigma \in S_n$ is any permutation of $1 \ldots n$, then we find the following isomorphy of the R-modules $M_1 \otimes \ldots \otimes M_n$ and $M_{\sigma(1)} \otimes \ldots \otimes M_{\sigma(n)}$

$$\begin{array}{rcl} M_1 \otimes \ldots \otimes M_n & \xrightarrow{\sim} & M_{\sigma(1)} \otimes \ldots \otimes M_{\sigma(n)} \\ \sum_{k=1}^{m} a_k \, x_{1,k} \otimes \ldots \otimes x_{n,k} & \mapsto & \sum_{k=1}^{m} a_k \, x_{\sigma(1),k} \otimes \ldots \otimes x_{\sigma(n),k} \end{array}$$

(ii) Suppose $I(1)$ to $I(s)$ are a partition of the set $1 \ldots n$, that is the $I(j)$ are pairwise disjoint [that is $j \neq k \implies I(j) \cap I(k) = \emptyset$ and also $I(1) \cup \cdots \cup I(s) = 1 \ldots n$]. Let $r(j) := \#I(j)$ and say $I(j)$ is given to be $I(j) = \{ i(j,1), \ldots, i(j, r(j)) \}$ for any $j \in 1 \ldots s$. Then we may rearrange the indexes $j \in 1 \ldots n$ arbitrarily and still find the following isomorphy of R-modules

$$\begin{array}{rcl} \bigotimes_{i=1}^{n} M_i & \xrightarrow{\sim} & \bigotimes_{j=1}^{s} \left(\bigotimes_{k=1}^{r(j)} M_{i(j,k)} \right) \\ \sum_{k=1}^{m} a_m \, x_{1,k} \otimes \ldots \otimes x_{n,k} & \mapsto & \sum_{k=1}^{m} a_k \, \otimes_{j=1}^{s} \left(\otimes_{k=1}^{r(j)} x_{i(j,k),k} \right) \end{array}$$

In particular, if L, M and N are R-modules then the tensor product is associative, up to isomorphy. That is the find the isomorphy of the R-modules $L \otimes (M \otimes N)$ and $(L \otimes M) \otimes N$, via:

$$\begin{array}{rcl} L \otimes (M \otimes N) & \xrightarrow{\sim} & (L \otimes M) \otimes N \\ \sum_{k=1}^{m} a_k \, x_k \otimes (y_k \otimes z_k) & \mapsto & \sum_{k=1}^{m} a_k \, (x_k \otimes y_k) \otimes z_k \end{array}$$

(iii) If A_1 to A_n even are R-(semi-)algebras, then the tensor product of these $A_1 \otimes \ldots \otimes A_n$ is an R-(semi-)algebra as well, where the multiplication is taken to be the following

$$\begin{array}{rcl} \left(\sum_{j=1}^{\ell} a_j \, x_{1,j} \otimes \ldots \otimes x_{n,j} \right) \cdot \left(\sum_{k=1}^{m} b_k \, y_{1,k} \otimes \ldots \otimes y_{n,k} \right) & & \\ := & \left(\sum_{j=1}^{\ell} \sum_{k=1}^{m} a_j \, b_k \, (x_{1,j} y_{1,k}) \otimes \ldots \otimes (x_{n,j} y_{n,k}) \right) & \end{array}$$

(3.145) Corollary: (viz. 1122)
Let $(R,+,\cdot)$ be a commutative ring and for any $i \in 1\ldots n$ consider an R-algebra A_i whose unit element we denote by $1_i \in A_i$. For any $x_1 \in A_1$ let us denote $\overline{x}_1 = x_1 \otimes 1_2 \otimes \ldots \otimes 1_n$ and so on, up to $\overline{x}_n = 1_1 \otimes \ldots \otimes 1_{n-1} \otimes x_n$ for some $x_n \in A_n$ That is $\overline{x}_j = \iota_j(x_j)$ where ι_j is the R-algebra-homomorphism

$$\iota_j \;:\; A_j \to \bigotimes_{i=1}^{n} A_i \;:\; x_j \mapsto \bigotimes_{i=1}^{n} \begin{cases} x_j \text{ if } i = j \\ 1_i \text{ if } i \neq j \end{cases}$$

Now let B be another R-semi-algebra and consider some R-algebra-homomorphisms $\alpha_i : A_i \to B$ such that for any $i \in 1\ldots n$ we have $\mathrm{im}(\alpha_i) \subseteq \mathrm{CEN}(B)$. Then there is a uniquely determined R-algebra-homomorphism

$$\overline{\alpha} \;:\; A_1 \otimes \ldots \otimes A_n \to B$$

such that for all $j \in 1\ldots n$ we get $\overline{\alpha}\iota_j = \alpha_j$ (that is $\overline{\alpha}(\overline{x}_j) = \alpha_j(x_j)$ for any $x_j \in A_j$). And this is explicitly given to be the following

$$\overline{\alpha}\left(\sum_{k=1}^{m} a_k\, x_{1,k} \otimes \ldots \otimes x_{n,k}\right) \;=\; \sum_{k=1}^{m} a_k\, \alpha_1(x_{1,k}) \cdot \cdots \cdot \alpha_n(x_{n,k})$$

(3.146) Proposition: (viz. 1122)
Let $(R,+,\cdot)$ be a commutative ring and consider the R-modules M and N. Then we study the result of applying the tensor product in the standard-cases:

(i) We obtain an isomorphy between $R \otimes M$ and M, as given below. In this sense the base ring R is the unit element of the tensor product

$$\begin{array}{rcl} R \otimes M & \xrightarrow{\sim} & M \\ \sum_{k=1}^{m} a_k \otimes x_k & \mapsto & \sum_{k=1}^{m} a_k x_k \end{array}$$

(ii) If $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is an ideal in R, then the quotient ring $R/\mathfrak{a}$ is an R-module under the scalar multiplication $a(b+\mathfrak{a}) = ab + \mathfrak{a}$. And taking to the tensor product we find the following isomorphy of R-modules

$$\begin{array}{rcl} R\big/_{\mathfrak{a}} \otimes M & \xrightarrow{\sim} & M\big/_{\mathfrak{a}M} \\ \sum_{k=1}^{m} a_k\,(b_k+\mathfrak{a}) \otimes x_k & \mapsto & \sum_{k=1}^{m} a_k b_k x_k + \mathfrak{a}M \end{array}$$

(iii) If $\mathfrak{a}$ and $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ are two ideals of R, then any element of the tensor product $(R/\mathfrak{a}) \otimes (R/\mathfrak{b})$ can be written in the form $(1+\mathfrak{a}) \otimes (r+\mathfrak{b})$ for some $r \in R$. And thereby we obtain an isomorphism of R-modules of the following form

$$\begin{array}{rcl} R\big/_{\mathfrak{a}} \otimes R\big/_{\mathfrak{b}} & \xrightarrow{\sim} & R\big/_{\mathfrak{a}+\mathfrak{b}} \\ (r+\mathfrak{a}) \otimes (s+\mathfrak{b}) & \mapsto & rs + (\mathfrak{a}+\mathfrak{b}) \end{array}$$

In particular (for $\mathfrak{a} = 0$ and $\mathfrak{b} = 0$) we obtain a very peculiar isomorphy of R to its tensor product $R \otimes R$ by virtue of the following map

$$R \otimes R \quad \xrightarrow{\sim} \quad R \;:\; a \otimes b \mapsto ab$$

(iv) Likewise, if $U \subseteq R$ is a multiplicatively closed set, then the localization $U^{-1}R$ is an R-module under the scalar multiplication $a(b/u) = (ab)/u$. And this time we find the following isomorphy of R-modules

$$\begin{array}{ccc} U^{-1}R \otimes M & \xrightarrow{\sim} & U^{-1}M \\ \displaystyle\sum_{k=1}^{m} a_k \, \frac{b_k}{u_k} \otimes x_k & \mapsto & \displaystyle\sum_{k=1}^{m} \frac{a_k b_k x_k}{u_k} \end{array}$$

(v) If M is a free module, then $M \otimes N$ is isomorphic to $\dim(M)$ copies of N. That is: If $\{ m_i \mid i \in I \}$ is an R-basis of M, then we obtain an isomorphism of the following R-modules

$$\begin{array}{ccc} N^{\oplus I} & \xrightarrow{\sim} & M \otimes N \\ (y_i) & \mapsto & \displaystyle\sum_{i \in I} m_i \otimes y_i \end{array}$$

(vi) If M and N both are free R-modules with the bases $\{ m_i \mid i \in I \}$ and $\{ n_j \mid j \in J \}$ respectively, then $M \otimes N$ is a free R-module with basis $\{ m_i \otimes n_j \mid i \in I, j \in J \}$. In particular we get

$$\dim(M \otimes N) \quad = \quad \dim(M) \cdot \dim(N)$$

And by induction it is clear, that if $M_1, \ldots, M_n$ are free R-modules with the bases $\{ m_{i,j} \mid i \in I(j) \}$ (where $j \in 1 \ldots n$) respectively, then the tensor product $M_1 \otimes \ldots \otimes M_n$ is a free R-module with the basis $\left\{ m_{i(1),1} \otimes \ldots \otimes m_{i(n),n} \mid i(1) \in I(1), \ldots, i(n) \in I(n) \right\}$.

(vii) The tensor product is compatible with direct sums: That is, if M_i (for $i \in I$) and N_j (for $j \in J$) are families of R-modules, then we obtain the following isomorphy of R-modules

$$\begin{array}{ccc} \left(\displaystyle\bigoplus_{i \in I} M_i \right) \otimes \left(\displaystyle\bigoplus_{j \in J} N_j \right) & \xrightarrow{\sim} & \displaystyle\bigoplus_{(i,j) \in I \times J} M_i \otimes N_j \\ \displaystyle\sum_{k=1}^{m} a_k (x_{i,k}) \otimes (y_{i,k}) & \mapsto & \displaystyle\sum_{k=1}^{m} a_k (x_{i,k} \otimes y_{j,k}) \end{array}$$

(viii) ($\diamondsuit$) Let A and B be commutative monoids and regard the polynomial rings $R[s \mid A]$ and $R[t \mid B]$ as R-algebras. Then $A \times B$ is a commutative monoid again such that we may also form the R-algebra $R[x \mid A \times B]$. And thereby we find that $R[x \mid A \times B]$ is nothing the tensor product of $R[s \mid A]$ and $R[t \mid B]$. That is we find the isomorphism of R-algebras

$$\begin{array}{ccc} R\left[x \mid A \times B\right] & \xrightarrow{\sim} & R\left[s \mid A\right] \otimes R\left[t \mid B\right] \\ \displaystyle\sum_{(\alpha,\beta) \in A \times B} f\left[\alpha, \beta\right] \, x^{(\alpha,\beta)} & \mapsto & \displaystyle\sum_{(\alpha,\beta) \in A \times B} f\left[\alpha, \beta\right] \, s^{\alpha} \otimes t^{\beta} \end{array}$$

And if A_1 to A_n are commutative monoids, then by induction on n it is clear that this generalizes to the following isomorphy of R-algebras

$$R[x \mid A_1 \times \cdots \times A_n] \quad \cong_{\mathsf{a}} \quad R[t \mid A_1] \otimes \ldots \otimes R[t \mid A_1]$$

(3.147) Remark:
Let us take a closer look at (3.146.(v)): As the elements of $N^{\oplus I}$ are of the form (y_i) where $y_i = 0$ for all but finitely many $i \in I$, we find that the elements of $t \in M \otimes N$ are of the form

$$t \quad \in \quad \sum_{i \in I} m_i \otimes y_i$$

where $\#\{\, i \in I \mid y_i \neq 0 \,\} < \infty$ again. In fact this representation of an element of $M \otimes N$ is *unique*. As $y = (y_i)$ and $y' = (y'_i)$ are equal $y = y'$ if an only if we have $y_i = y'_i$ for any $i \in I$ this property is transferred to $M \otimes N$. That is in $M \otimes N$ we find the equivalence of

$$\sum_{i \in I} m_i \otimes y_i \;=\; \sum_{i \in I} m_i \otimes y'_i \quad \Longleftrightarrow \quad \forall\, i \in I \;:\; y_i = y'_i$$

(3.148) Definition:
Let $(R, +, \cdot)$ be a commutative ring and let $\varphi_i : M_i \to N_i$ (where $i \in 1 \ldots n$) be R-module homomorphisms between the R-modules M_i and N_i. Then we obtain an R-multi-linear map, by letting

$$\begin{aligned} \varphi_1 \times \cdots \times \varphi_n \quad &: \quad M_1 \times \cdots \times M_n \to N_1 \otimes \ldots \otimes N_n \\ &: \quad (x_1, \ldots, x_n) \mapsto \varphi(x_1) \otimes \ldots \otimes \varphi(x_n) \end{aligned}$$

And according to the universal property (3.142) this induces an R-linear map, which we denote by $\varphi_1 \otimes \ldots \otimes \varphi_n := \overline{\varphi_1 \times \cdots \times \varphi_n}$ and which is explicitly given to be

$$\begin{aligned} \varphi_1 \otimes \ldots \otimes \varphi_n \quad &: \quad M_1 \otimes \ldots \otimes M_n \to N_1 \otimes \ldots \otimes N_n \\ &: \quad \sum_{k=1}^{m} a_k\, x_{1,k} \otimes \ldots \otimes x_{n,k} \mapsto \sum_{k=1}^{m} a_k\, \varphi_1(x_{1,k}) \otimes \ldots \otimes \varphi_n(x_{n,k}) \end{aligned}$$

This map is called the **tensor product** of the φ_i. It is common practice that in case of φ_i being the identity map $\varphi_i = \mathbb{1}_i : M_i \to N_i = M_i : x \mapsto x$ we will just write $\varphi_1 \otimes \ldots \otimes M_i \otimes \ldots \otimes \varphi_n$, instead of $\varphi_1 \otimes \ldots \otimes \mathbb{1}_i \otimes \ldots \otimes \varphi_n$.

(3.149) Lemma: (viz. 1128)
Let $(R, +, \cdot)$ be a commutative ring and let $\varphi_i : L_i \to M_i$ and $\psi_i : M_i \to N_i$ (where $i \in 1 \ldots n$) be R-module homomorphisms between the R-modules L_i and M_i and N_i respectively.

(i) Let $\mathbb{1}_i : M_i \to M_i : x \mapsto x$ be the identity map on M_i. Then the tensor product of the $\mathbb{1}_i$ is the identity map on $M_1 \otimes \ldots \otimes M_n$, formally that is

$$\mathbb{1}_1 \otimes \ldots \otimes \mathbb{1}_n \;=\; \mathbb{1}_{M_1 \otimes \ldots \otimes M_n} \;:\; t \mapsto t$$

(ii) The tensor product of homomorphisms is compatible with the composition of maps, which is to say

$$\left(\bigotimes_{i=1}^{n}\psi_i\right)\left(\bigotimes_{i=1}^{n}\varphi_i\right) \;=\; \bigotimes_{i=1}^{n}(\psi_i\varphi_i)$$

(iii) If all the φ_i are surjective (respectively bijective), then the tensor product $\otimes_{i=1}^{n}\varphi_i$ is surjective (respectively bijective) again. And in case R is a field we also get: If all the φ_i are injective, then the tensor product $\otimes_{i=1}^{n}\varphi_i$ is injective again.

(iv) In case R is an arbitrary commutative ring we still get: If for any $i \in 1\ldots n$ we have that (1) φ_i is injective and (2) there is some sub-module $P_i \leq_{\mathfrak{m}} M_i$ such that $\mathrm{im}(\varphi_i) \oplus P_i = M_i$ then we get that (a) $\varphi_1 \otimes \ldots \otimes \varphi_n$ is injective and (b) there is some sub-module $P \leq_{\mathfrak{m}} M_1 \otimes \ldots \otimes M_n$ such that

$$M_1 \otimes \ldots \otimes M_n \;=\; \mathrm{im}(\varphi_1 \otimes \ldots \otimes \varphi_n) \oplus P$$

(3.150) Remark:
Consider the R-modules M, M' and N over the commutative ring $(R,+,\cdot)$ and suppose $\Phi : M \xrightarrow{\sim} M'$ is an isomorphism. Then by (3.149.(iii)) $\Phi \otimes \mathbb{1}_N$ is an isomorphism, as well. And it is of the form

$$M \otimes N \;\xrightarrow{\sim}\; M' \otimes N \;:\; \sum_{k=1}^{m} a_k\, x_k \otimes y_k \mapsto \sum_{k=1}^{m} a_k\, \Phi(x_k) \otimes y_k$$

Therefore any isomorphy of modules is preserved if we append another module using a tensor product. We will use this property to prove the following statements:

(3.151) Corollary: (viz. 1129)
Let $(R,+,\cdot)$ be a commutative ring, $U \subseteq R$ be a multiplicatively closed set and denote $S := U^{-1}R$. If now M and N are two R-modules, then we obtain the following isomorphies

(i) If we regard $U^{-1}M$ and $U^{-1}N$ as R-modules again, then we obtain an isomorphism of R-modules that is defined by linear expansion of

$$\begin{array}{ccc} U^{-1}M \otimes U^{-1}N & \xrightarrow{\sim} & U^{-1}(M \otimes N) \\ \frac{x}{u} \otimes \frac{y}{v} & \mapsto & \frac{x \otimes y}{uv} \end{array}$$

(ii) By construction $U^{-1}M$ and $U^{-1}N$ are S-modules, but we can also regard these as R-modules. We denote this by using the index R, as in (3.124). Then we find the following isomorphy of R-modules

$$\begin{array}{ccc} \left(U^{-1}M\right)_R \otimes_R \left(U^{-1}N\right)_R & \xrightarrow{\sim} & \left(U^{-1}M \otimes_S U^{-1}N\right)_R \\ \frac{x}{u} \otimes_R \frac{y}{v} & \mapsto & \frac{x}{u} \otimes_S \frac{y}{v} \end{array}$$

(3.152) Remark: (viz. 1133)
Kronecker Product: Let $(R,+,\cdot)$ be a commutative ring and $\varphi : M \to N$ and $\psi : U \to V$ be homomorphisms between the R-modules M, N, U and V. Suppose all these modules are finitely generated, free and let us denote the bases of these by $\mathcal{M} = \{ m_j \mid j \in 1 \dots n \}$ of M, $\mathcal{N} = \{ n_i \mid i \in 1 \dots m \}$ of N, $\mathcal{U} = \{ u_l \mid l \in 1 \dots q \}$ of U and finally $\mathcal{V} = \{ v_k \mid k \in 1 \dots p \}$ of V. Also let $[\varphi] = A = (a_{i,j}) \in \mathrm{mat}_{m,n}(R)$ and $[\psi] = B = (b_{k,l}) \in \mathrm{mat}_{p,q}(R)$ be the matrix representations of φ and ψ respectively. That is we have

$$\varphi(m_j) \;=\; \sum_{i=1}^{m} a_{i,j} n_i \quad \text{and} \quad \psi(u_l) \;=\; \sum_{k=1}^{p} b_{k,l} v_k$$

By (3.146.(v)) $M \otimes U$ inherits the basis $\{ m_j \otimes u_l \mid (j,l) \in (1 \dots n) \times (1 \dots q) \}$ and in particular is a free $(n \cdot q)$-dimensional module. Likewise $N \otimes V$ is a free $(m \cdot p)$-dimensional module, as it features the basis $\{ n_i \otimes v_k \mid (i,k) \in (1 \dots m) \times (1 \dots p) \}$. Due to the multi-linearity of the tensor product we find

$$(\varphi \otimes \psi)(m_j \otimes u_l) \;=\; \varphi(m_j) \otimes \psi(u_l) \;=\; \sum_{i=1}^{m} \sum_{k=1}^{p} a_{i,j} b_{k,l}\, n_i \otimes v_k$$

From this we find the matrix representation of $\varphi \otimes \psi : M \otimes U \to N \otimes V$ to be composed of the products $a_{i,j} b_{k,l}$ of the coefficients of A and B, that is

$$[\varphi \otimes \psi]_{(i,k),(j,l)} \;=\; a_{i,j} b_{k,l} \;=\; [\varphi]_{i,j}\, [\psi]_{k,l}$$

We need to order the bases of $M \otimes U$ and $N \otimes V$ to fix a matrix representation of $\varphi \otimes \psi$. So we install the lexicographic order $(1,1) < (1,2) < \dots < (1,p) < (2,1) < \dots < (m,p)$. That is $(i,k) = p(i-1)+k \in 1 \dots mp$ and $(j,l) = q(j-1)+l \in 1 \dots nq$. It stands to reason to denote this so called **kronecker product** of the matrices A and B by $A \otimes B$ again. That is we define $A \otimes B \in \mathrm{mat}_{mp,nq}(R)$ to be $[A \otimes B]_{(i,k),(j,l)} := [A]_{i,j} \cdot [B]_{k,l} \in R$. In block form this reads as

$$A \otimes B \;=\; \begin{pmatrix} a_{1,1}B & \cdots & a_{1,n}B \\ \vdots & & \vdots \\ a_{m,1}B & \cdots & a_{m,n}B \end{pmatrix}$$

e.g.

$$\begin{pmatrix} 0 & 1 & 0 \\ 2 & 0 & 3 \\ 0 & 4 & 0 \end{pmatrix} \otimes \begin{pmatrix} a & 2 \\ 0 & 1 \end{pmatrix} \;=\; \begin{pmatrix} 0 & 0 & a & 2 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 2a & 4 & 0 & 0 & 3a & 6 \\ 0 & 2 & 0 & 0 & 0 & 3 \\ 0 & 0 & 4a & 8 & 0 & 0 \\ 0 & 0 & 0 & 4 & 0 & 0 \end{pmatrix}$$

Recall that we defined the kronecker product of two matrices in precisely that way, as to ensure the following equality of matrix representations:

$$[\varphi \otimes \psi] \;=\; [\varphi] \otimes [\psi]$$

And using (3.149) or direct computations, it is clear, that the kronecker product features the properties

$$\begin{aligned}
\mathbb{1}_m \otimes \mathbb{1}_n &= \mathbb{1}_{mn} \\
A \otimes B &= (A \otimes \mathbb{1}_p)(\mathbb{1}_n \otimes B) \\
A \otimes (bB + D) &= b(A \otimes B) + (A \otimes D) \\
(aA + C) \otimes B &= a(A \otimes B) + (C \otimes B) \\
(A \otimes B)^* &= A^* \otimes B^* \\
(A \otimes B)(C \otimes D) &= (AC) \otimes (BD) \\
\mathrm{tr}(A \otimes B) &= \mathrm{tr}(A) \cdot \mathrm{tr}(B)
\end{aligned}$$

After these all these examples it should be understood, that the tensor product is very well-behaved and highly compatible with all the different constructions we employed so far. That is the *external* structure of tensor products is immaculate indeed.
But looking at the proofs we see that all these properties have been derived by constructing the required isomorphisms using the universal property. We rarely employed computations with tensor elements. This is due to the sad fact that the *internal* structure of the tensor product is very hard to control: Lots of weird things can happen if we look at the tensor elements directly, as T is hard to control directly. However dealing with free modules the internal structure of the tensor product is well domesticated, as well. To get a glimpse of this compare (3.153) to (3.154.(i)).

(3.153) Proposition: (viz. 1148)
Let $(R, +, \cdot)$ be a commutative ring, M and N be R-modules. Suppose we are given a generating set of $N = \mathrm{Lh}\{ n_j \mid j \in J \}$ and a family of elements $\{ m_j \mid j \in J \} \subseteq M$ such that only finitely many m_j are non-zero [that is $\#\{ j \in J \mid m_j \neq 0 \} < \infty$]. Then

$$\sum_{j \in J} m_j \otimes n_j = 0$$

is zero, if and only if there are some elements x_1 to $x_m \in M$ and scalars $a_{i,j} \in R$ (where $i \in 1 \dots m$ and $j \in J$) such that only finitely many $a_{i,j}$ are non-zero [that is $\#\{ (i,j) \in 1 \dots m \times J \mid a_{i,j} \neq 0 \} < \infty$] such that the following two properties hold true

$$\begin{aligned}
\forall\, i \in 1 \dots m &: \sum_{j \in J} a_{i,j} n_j = 0 \\
\forall\, j \in J &: m_j = \sum_{i=1}^{m} a_{i,j} x_j
\end{aligned}$$

(3.154) Proposition: (viz. 1134)
Let $(E, +, \cdot)$ be a field and $M_1, \dots, M_n$ be E-modules (which are free automatically, since E is a field). Now consider some elements $x_i, y_i \in M_i$ (where $i \in 1 \dots n$), then we obtain the following statements

(i) The tensor product $x_1 \otimes \dots \otimes x_n = 0$ is zero if and only if we have $x_i = 0$ for some $i \in 1 \dots n$ [the implication $\exists\, i \in 1 \dots n : x_i = 0 \implies x_1 \otimes \dots \otimes x_n = 0$ is true over arbitrary commutative rings, the converse direction uses the fact that all the M_i are free, however].

(ii) We have the equality $x_1 \otimes \ldots \otimes x_n = y_1 \otimes \ldots \otimes y_n \neq 0$ if and only if there are some $a_1, \ldots, a_n \in E$ such that (1) $y_i = a_i x_i$ for all $i \in 1 \ldots n$ and (2) $a_1 \ldots a_n = 1$.

(iii) For any $i \in 1 \ldots n$ let $X_i \subseteq M_i$ be a non-empty ($X_i \neq \emptyset$) subset of M_i and let us denote the following subset of $M_1 \otimes \ldots \otimes M_n$

$$X_1 \otimes \ldots \otimes X_n \;:=\; \{\, x_1 \otimes \ldots \otimes x_n \mid \forall\, i \in 1 \ldots n : x_i \in X_i \,\}$$

Now let $\star$ replace any of the properties *generates*, *is a linear independent subset of* or *is a basis of*. Then we get the following three implications

$$\forall\, i \in 1 \ldots n \;:\; X_i \;\star\; M_i \quad\Longrightarrow\quad X_1 \otimes \ldots \otimes X_n \;\star\; M_1 \otimes \ldots \otimes M_n$$

[Note that the assumption of E being a field is only required for $\star =$ *is linear independent in*. The other two implications remain true over arbitrary commutative rings E].

(iv) If $U_i \;\leq_{\mathsf{m}}\; M_i$ (where $i \in 1 \ldots n$) are subspaces of the M_i then the map $\otimes_{i=1}^n U_i \to \otimes_{i=1}^n M_i : \otimes_{i=1}^n x_i \mapsto \otimes_{i=1}^n x_i$ is injective. And in this sense we can interpret $\otimes_{i=1}^n U_i \;\leq_{\mathsf{m}}\; \otimes_{i=1}^n M_i$ as a subspace of $M_1 \otimes \ldots \otimes M_n$ again

$$\bigotimes_{i=1}^n U_i = \left\{ \sum_{k=1}^m a_k\, u_{1,k} \otimes \ldots \otimes u_{n,k} \;\middle|\; a_k \in E, u_{i,k} \in M_i \right\} \leq_{\mathsf{m}} \bigotimes_{i=1}^n M_i$$

And if $U_{i,j} \;\leq_{\mathsf{m}}\; M_i$ (where $j \in J(i)$) are arbitrary families of subspaces of the M_i, then we also find the following equality of subsets of $M_1 \otimes \ldots \otimes M_n$

$$\bigotimes_{i=1}^n \left(\bigcap_{j \in J(i)} U_{i,j} \right) \;=\; \bigcap_{j \in J(1) \times \ldots J(n)} \bigotimes_{i=1}^n U_{i,j(i)}$$

(v) Let again $U_i \;\leq_{\mathsf{m}}\; M_i$ (where $i \in 1 \ldots n$) be subspaces of the M_i and consider some $a_k \in E$ with $a_k \neq 0$ and $x_{i,k} \in M_i$ (where $i \in 1 \ldots n$ and $k \in 1 \ldots m$) such that for any $i \in 1 \ldots n$ the set $\{\, x_{i,k} \mid k \in 1 \ldots m \,\} \subseteq M_i$ is linear independent. Then we get the equivalence

$$\sum_{k=1}^m a_k\, x_{1,k} \otimes \ldots \otimes y_{i,k} \;\in\; \bigotimes_{i=1}^n U_i \quad\Longleftrightarrow\quad \begin{array}{c} \forall\, i \in 1 \ldots n \\ \forall\, k \in 1 \ldots m \\ x_{i,k} \in U_i \end{array}$$

We will now restrict to the case $n = 2$, that is we consider any two modules M and N over the field E. Then we further get the following statements:

(vi) If $x_1, \ldots, x_m \in M$ are linear independent and $y_1, \ldots, y_m \in N$ and $y'_1, \ldots, y'_m \in N$ are arbitrary elements in N, then we get

$$\sum_{k=1}^m x_k \otimes y_k \;=\; \sum_{k=1}^m x_k \otimes y'_k \quad\Longrightarrow\quad \forall\, k \in 1 \ldots m \;:\; y_k = y'_k$$

(vii) Now pick up an arbitrary tensor element $t = \sum_{k=1}^{m} a_k\, x_k \otimes y_k \in M \otimes N$. Then the number m of pure tensors in this representation is minimal (that is $m = \mu(t)$) iff all of the following three conditions are met

(1) $\forall\, k \in 1 \ldots m \;:\; a_k \neq 0$

(2) $\{\, x_k \mid k \in 1 \ldots m \,\} \subseteq M$ is E-linearly independent

(3) $\{\, y_k \mid k \in 1 \ldots m \,\} \subseteq N$ is E-linearly independent

In particular every tensor element $t \in M \otimes N$ admits a representation $t = \sum_r a_r\, u_r \otimes v_r$ with $a_r \neq 0$ and $\{\, u_1, \ldots, u_s \,\} \subseteq M$ and $\{\, v_1, \ldots, v_s \,\} \subseteq N$ E-linearly independent.

(3.155) Theorem: (viz. 1145)
Let $(R, +, \cdot)$ be a commutative ring and M and N be R-modules. Then we obtain the following statements

(i) If M is finitely generated and $\star$ abbreviates any one of the following properties *finitely generated*, *noetherian* or *artinian*, then we get the following implication:

$$N \text{ is } \star \quad \Longrightarrow \quad M \otimes N \text{ is } \star$$

(ii) And if $\star$ abbreviates any one of the properties *finitely generated*, *free*, *noetherian*, *artinian* or *has a finite free presentation*, then we get the following implication:

$$M \text{ and } N \text{ are } \star \quad \Longrightarrow \quad M \otimes N \text{ is } \star$$

(iii) Moreover, if both M and N have finite length, then the tensor product has finite length, as well and we find the inequality

$$\ell(M \otimes N) \;\leq\; \ell(M) \cdot \ell(N)$$

(iv) In the fancy language of homological algebra the following property can be put shortly as: *The tensor functor is right-exact*. This is to say: Consider any exact chain of R-modules, of the form

$$U \xrightarrow{\varphi} V \xrightarrow{\psi} W \to 0$$

Then tensoring such a chain with M from the right, we obtain another exact chain of R-modules

$$U \otimes M \xrightarrow{\varphi \otimes M} V \otimes M \xrightarrow{\psi \otimes M} W \otimes M \to 0$$

(v) Consider two *right-exact* chains of R-modules, i.e. exact chains of R-modules, of the following form

$$M_0 \xrightarrow{\varphi_1} M_1 \xrightarrow{\varphi_2} M_2 \to 0$$

$$N_0 \xrightarrow{\psi_1} N_1 \xrightarrow{\psi_2} N_2 \to 0$$

Then we can explicitly give the kernel of the tensor map $\varphi_2 \otimes \psi_2$ to be the following submodule

$$\mathrm{kn}(\varphi_2 \otimes \psi_2) \;=\; \mathrm{im}(\varphi_1 \otimes N_1) + \mathrm{im}(M_1 \otimes \psi_1)$$

(3.156) Remark:
As we have just seen in, the tensor product preserves right-exact chains of R-modules. This already implies, that the tensor product preserves surjectivity. This is to say: Consider any R-modules M, U and V over a commutative ring $(R, +, \cdot)$ and let $\varphi : U \twoheadrightarrow V$ be a surjective homomorphism of R-modules. Then the map $\varphi \otimes M$ is surjective, as well:

$$\varphi \otimes M \ : \ U \otimes M \ \twoheadrightarrow \ V \otimes M$$

Prob we can extend $\varphi : U \twoheadrightarrow V$ to an exact chain $\ker(\varphi) \to U \to V \to 0$, by taking $\subseteq : \ker(\varphi) \to U$ as a homomorphism. Then by (3.155.(vi)) $\ker(\varphi) \otimes M \to U \otimes M \to V \otimes M \to 0$ is exact again. In particular $\varphi \otimes M : U \otimes M \to V \otimes M$ is surjective.

(3.157) Example:
Note that the right-exactness of the tensor functor cannot be generalized, as a counter-example consider the following exact chain of $\mathbb{Z}$-modules

$$0 \to \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z}$$

where $\cdot 2$ denotes the linear map $k \mapsto 2k$. Tensoring this with $\mathbb{Z}_2$ we arrive the following non-exact chain of modules (see below). It is non-exact, as for any $k \in \mathbb{Z}$ and any $b \in \mathbb{Z}_2$ we clearly have $k \otimes b \mapsto (2k) \otimes b = k \otimes (2b) = k \otimes 0 = 0$, hence $\cdot 2 \otimes \mathbb{1}$ is the zero-homomorphism and thereby certainly not injective, as $\mathbb{Z} \otimes \mathbb{Z}_2 \ \cong_{\mathfrak{m}} \ \mathbb{Z}_2$.

$$0 \to \mathbb{Z} \otimes \mathbb{Z}_2 \xrightarrow{\cdot 2 \otimes \mathrm{id}} \mathbb{Z} \otimes \mathbb{Z}_2$$

Change of Base Rings:

(3.158) Definition:
Suppose $(R, +, \cdot)$ is a commutative ring, M is an R-module and S is an R-algebra. Then $S \otimes M$ is an R-module, but in complete analogy to (3.144.(iii)) above it also is an S-module under the scalar multiplication (where $a_i \in R$, $x_i \in M$ and $r, s_i \in S$)

$$r \left(\sum_{i=1}^{n} a_i \, s_i \otimes x_i \right) \ := \ \sum_{i=i}^{n} a_i \, (r s_i) \otimes x_i$$

That is by tensoring the R-module M with S we end up with an S-module $S \otimes M$. This construction is hence known as *change of base rings*. And we will denote

$$M_S \ := \ S \otimes M$$

to emphasize that we now regard M_S as an S-module (not as an R-module any longer). Recall that given two R-modules M and N and an R-module homomorphism $\varphi : M \to N$ we also get an R-module homomorphism $S \otimes \varphi$ by virtue of

$$\varphi_S \ := \ S \otimes \varphi \ : \ \sum_{i=1}^{n} a_i \, s_i \otimes x_i \mapsto \sum_{i=1}^{n} a_i \, s_i \otimes \varphi(x_i)$$

If r, $s \in S$ and $x \in M$, then $\varphi_S(r(s \otimes x)) = \varphi_S((rs) \otimes x) = (rs) \otimes \varphi(x) = r(s \otimes \varphi(x)) = r\varphi_S(s \otimes x)$ such that φ_S already is S-linear, too. Therefore we can always regard φ_S as an S-module-homomorphism from M_S to N_S.

(3.159) Example: (viz. 1143)
Let us recollect some examples of (3.146) that illustrate why the name "change of base rings" is well-chosen: If $(R, +, \cdot)$ is a commutative ring, M is an R-module, $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is an ideal and $U \subseteq R$ is a multiplicatively closed set, then we have the following isomorphies [of modules over the new base ring, that is as R-, $(R/\mathfrak{a})$- or resp. of $U^{-1}R$-modules]

$$M_R \xrightarrow{\sim} M : a \otimes x \mapsto ax$$

$$M_{R/\mathfrak{a}} \xrightarrow{\sim} M \Big/ {}_{\mathfrak{a}M} : (b + \mathfrak{a}) \otimes x \mapsto bx + \mathfrak{a}M$$

$$M_{U^{-1}R} \xrightarrow{\sim} U^{-1}M : \frac{a}{u} \otimes x \mapsto \frac{ax}{u}$$

And if S is an arbitrary R-algebra, $(A, +)$ is a commutative monoid, then the change of base rings turns the R-algebra of polynomials over R into the S-algebra of polynomials over S. That is we find an isomorphy of S-algebras, by linear expansion of

$$R[t \mid A]_S \xrightarrow{\sim} S[t \mid A] : s \otimes f \mapsto sf$$

Also if the R-algebra S satisfies $\{ a1_S \mid a \in R \} \subseteq \mathrm{CEN}(S)$ and we fix some $1 \leq m$, $n \in \mathbb{N}$ then the change of base rings turns the R-algebra of matrices over R into the S-algebra of matrices over S. That is we find an isomorphy of S-algebras, by linear expansion of

$$\Big(\mathrm{mat}_{m,n}(R)\Big)_S \xrightarrow{\sim} \mathrm{mat}_{m,n}(S) : s \otimes A \mapsto sA$$

Note that in all of these examples the pure tensor $s \otimes x$ is mapped onto the scalar product sx of the "traditional" S-module. This illustrates how canonical the change of base rings is.

(3.160) Proposition: (viz. 1139)
Let $(R, +, \cdot)$ be a commutative ring, S be an (not necessarily commutative) R-algebra and let M be an R-module. Then we get the following properties

(i) If M is a free R-module, with R-basis $\{ m_i \mid i \in I \}$ then M_S is a free S-module with S-basis $\{ 1_S \otimes m_i \mid i \in I \}$. In particular we get

$$\dim_S(M_S) = \dim_R(M)$$

(ii) $(\diamondsuit)$ Let M be a free R-module with finite basis $\{ m_j \mid j \in 1 \ldots n \}$ again. Also let N be a free R-module with finite basis $\{ n_i \mid i \in 1 \ldots m \}$. Finally let $\varphi : M \to N$ be an R-module-homomorphism with matrix representation $[\varphi] = (a_{i,j}) \in \mathrm{mat}_{m,n}(R)$, that is

$$\varphi(m_j) = \sum_{i=1}^{m} a_{i,j} n_i$$

If we now fix the S-bases $\{ 1_S \otimes m_j \mid j \in 1 \ldots n \}$ on M_S and likewise $\{ 1_S \otimes n_i \mid i \in 1 \ldots m \}$ on N_S, then $\varphi_S : M_S \to N_S$ has the basis representation $[\varphi] = (a_{i,j} 1_S) \in \mathrm{mat}_{m,n}(S)$, that is

$$\varphi(1_S \otimes m_j) \;=\; \sum_{i=1}^{m} (a_{i,j} 1_S)(1_S \otimes n_i)$$

(iii) If $S \neq 0$ is a free R-algebra, then the canonical homomorphism $M \hookrightarrow M_S : x \mapsto 1_S \otimes x$ is injective.

(iv) *Transitivity of the Change of base Rings*: If A is a commutative R-algebra and B is a (not necessarily commutative) A-algebra, then we find the following isomorphy of B-modules:

$$\Big(M_A\Big)_B \xrightarrow{\sim} M_B \;:\; b \otimes (a \otimes x) \mapsto (ab) \otimes x$$

(v) If S is a commutative R-algebra and $M(i)$ is a family of R-modules (where $i \in 1 \ldots n$) then the change of base rings is compatible with the tensor product: We obtain an isomorphy of S-modules

$$\big(M(1) \otimes_R \ldots \otimes_R M(n)\big)_S \quad\xrightarrow{\sim}\quad M(1)_S \otimes_S \ldots \otimes_S M(n)_S$$

$$1_S \otimes (x_1 \otimes \ldots \otimes x_n) \quad\mapsto\quad (1_S \otimes x_1) \otimes \ldots \otimes (1_S \otimes x_n)$$

(vi) Consider an S-module N, this can be turned into an R-module, as well, using the scalar multiplication $an := (a1_S)n$. If now $\varphi : M \to N$ is an R-module-homomorphism [that is $\varphi(ax) = (a1_S)\varphi(x)$] then there is a uniquely determined S-module-homomorphism $\varphi_{(S)} : M_S \to N$ such that for any $x \in M$ we get $\varphi_{(S)}(1_S \otimes m) = \varphi(x)$. And this is given by

$$\varphi_{(S)} \;:\; M_S \to N \;:\; \sum_{k=1}^{m} a_k s_k \otimes x_k \mapsto \sum_{k=1}^{m} (a_k s_k)\varphi(x_k)$$

And we thereby find that the map $\varphi \mapsto \varphi_S$ is an isomorphism of R-modules whose inverse is given to be $\psi \mapsto (x \mapsto \psi(1_S \otimes x))$, altogether that is

$$\begin{array}{rcl} \mathrm{mhom}_R(M,N) & \xrightarrow{\sim} & \mathrm{mhom}_S(M_S,N) \\ \varphi & \mapsto & \varphi_{(S)} \\ \big(x \mapsto \psi(1_S \otimes x)\big) & \leftarrow\!\shortmid & \psi \end{array}$$

If S is commutative then this map even is an isomorphism of S-modules [note that since N is an S-module $s\varphi : x \mapsto s\varphi(x)$ makes sense].

(vii) If A is an R-(semi-)algebra, B is an S-(semi-)algebra and $\varphi : A \to B$ is a homomorphism of R-(semi-)algebras, then $\varphi_{(S)} : A_S \to B$ is a homomorphism of S-(semi-)algebras again.

(3.161) Proposition: (viz. 1142)
Let $(E,+,\cdot)$ be a field, S a (not necessarily commutative) E-algebra and consider two E-vector-spaces U and V. If now $\varphi : U \to V$ is any E-linear map, then we get the following properites:

(i) Let $\star$ abbreviate any of the words *injective*, *surjective* or *bijective* and suppose φ is $\star$. Then the induced map φ_S is $\star$ as well

$$\varphi \text{ is } \star \iff \varphi_S \text{ is } \star$$

(ii) If $\{ u_i \mid i \in I \} \subseteq U$ is an E-basis of $\mathrm{kn}(\varphi)$, then $\{ 1_S \otimes u_i \mid i \in I \} \subseteq U_S$ is a S-basis of $\mathrm{kn}(\varphi_S)$. And thereby we can write the kernel of φ_S in the following form

$$\mathrm{kn}(\varphi_S) \;=\; \mathrm{Lh}_S\{ 1_S \otimes u \mid u \in \mathrm{kn}(\varphi) \}$$

(iii) If $\{ v_j \mid j \in J \} \subseteq V$ is an E-basis of $\mathrm{im}(\varphi)$, then $\{ 1_S \otimes v_j \mid j \in J \} \subseteq V_S$ is a S-basis of $\mathrm{im}(\varphi_S)$. And thereby we can write the image of φ_S in the following form

$$\mathrm{im}(\varphi_S) \;=\; \mathrm{Lh}_S\{ 1_S \otimes v \mid v \in \mathrm{im}(\varphi) \}$$

(iv) If S is a field as well, then φ and φ_S share the same rank (over their respective base fields), i.e.

$$\mathrm{rank}_S(\varphi_S) \;=\; \mathrm{rank}_E(\varphi)$$

(3.162) Proposition: (viz. 1143)
As always let $(R,+,\cdot)$ be a commutative ring and consider M, N two R-modules. Also let $S \neq 0$ be an arbitrary non-zero R-algebra. Then we obtain a well-defined, S-linear map, by S-linear expansion of

$$\mu \;:\; \big(\mathrm{mhom}_R(M,N)\big)_S \to \mathrm{mhom}_S(M_S,N_S)$$

$$\mu \;:\; s \otimes \varphi \mapsto s\,\varphi_S$$

(i) If S is free, then μ is injective.

(ii) If S is free and finite-dimensional, then μ is bijective.

(iii) If M and N are free and finite-dimensional, then μ is bijective.

(3.163) Example:
The most common application of the change of base rings is the *complexification of real vector spaces*, that is we start with an $\mathbb{R}$-vectorspace V and use change of base rings to replace $\mathbb{R}$ by $\mathbb{C}$

$$V_{\mathbb{C}} \;=\; \mathbb{C} \otimes_{\mathbb{R}} V$$

As $\mathbb{C}$ is a free $\mathbb{R}$-algebra, having the basis $\{1,i\}$, we can interpret V as a subspace of $V_{\mathbb{C}}$ under the canonical embedding

$$V \hookrightarrow V_{\mathbb{C}} \;:\; x \mapsto 1 \otimes x$$

And if $\{ v_k \mid k \in K \} \subseteq V$ is an $\mathbb{R}$-basis of V, then $V_{\mathbb{C}}$ has the $\mathbb{C}$-basis $\{ 1 \otimes v_k \mid k \in K \}$ again. On the other hand (3.146.(vi)) tells us, that an $\mathbb{R}$-basis of $V_{\mathbb{C}}$ is now given, by $\{ 1 \otimes v_k \mid k \in K \} \cup \{ i \otimes v_k \mid k \in K \}$. Using the embedding $x \mapsto 1 \otimes x$ we find that $1 \otimes v_k = v_k$ and $i \otimes v_k = i(1 \otimes v_k) = iv_k$. That is $V_{\mathbb{C}}$ has the $\mathbb{R}$-basis $\{ v_k \mid k \in K \} \cup \{ iv_k \mid k \in K \}$ and therefore

$$\dim_{\mathbb{C}}(V_{\mathbb{C}}) \;=\; \dim_{\mathbb{R}}(V) \text{ and } \dim_{\mathbb{R}}(V_{\mathbb{C}}) \;=\; 2 \cdot \dim_{\mathbb{R}}(V)$$

Hence the complexification $V_{\mathbb{C}}$ is isomorphic (as an $\mathbb{R}$-vectorspace) to two copies $V \oplus V$ of V under the following $\mathbb{R}$-vectorspace isomorphism. And under this isomorphism the scalar multiplication $\mathbb{C} \times V_{\mathbb{C}} \to V_{\mathbb{C}}$ which is given by $(c, x) \mapsto c \otimes x$ becomes the following $\mathbb{R}$-bilinear map

$$V \oplus V \;\xrightarrow{\sim}\; V_{\mathbb{C}} \;:\; \left(\sum_{k \in K} a_k v_k, \sum_{k \in K} b_k v_k \right) \mapsto \sum_{k \in K} (a_k + ib_k) \otimes v_k$$

$$\mathbb{C} \times V^{\oplus 2} \to V^{\oplus 2} \;:\; (a + bi, (x, y)) \mapsto (ax - by, bx + ay)$$

Many ad-hoc constructions of $V_{\mathbb{C}}$ employ this technique: They define $\mathbb{V}_{\mathbb{C}}$ to be $V^{\oplus 2}$ and define the scalar multiplication $\mathbb{C} \times V^{\oplus 2} \to V^{\oplus 2}$ using this $\mathbb{R}$-bilinear map. While there's nothing wrong with that, it remains to prove the properties of a $\mathbb{C}$-vectorspace, in this case.

3.14 Direct Limits

This section is somewhat more advanced and can be safely skipped, at a first reading. We will introduce two constructions, the direct and inverse limits of modules. These will be the algebraic answer to problems of approximation and convergence. A special case are adic completions and completion of topological spaces. You already see here, that this concept is quite general - it can be done with groups, rings, modules, ... even with topological spaces. This is where we will use or $\star$ again. We will not take the categorial point of view yet, but regard several categories at once - without the formal background. E.g. we are primarily interested in modules M over a fixed, commutative ring $(R, +, \cdot)$. Then the *objects* are R-modules and the *morphisms* are R-module-homomorphisms - that is R-linear maps. We will regard related situations simultaneously. Hence throughout this section we install the following nomenclature: We speak of $\star$-objects and the corresponding $\star$-morphisms, as summarized in the following table.

$\star$-objects	$\star$-morphisms	$\hom(M,N)$
sets	functions	$\mathcal{F}(M,N)$
(commutative) groups	group-homomorphisms	$\mathrm{ghom}(M,N)$
R-modules	R-module-homomorphisms	$\mathrm{mhom}(M,N)$
(commutative) rings	ring-homomorphisms	$\mathrm{rhom}(M,N)$
(commutative) R-algebras	R-algebra-homomorphisms	$\mathrm{ahom}(M,N)$
topological spaces	continuous maps	$C(M,N)$

Note that in case of R-modules and R-algebras, the base ring R is assumed to be commutative and the same for all $\star$-objects. The notion of topological spaces will be introduced in section 6.1. As they play a special role, let us agree to call the upper five kinds of $\star$-objects (that is all here, except topological spaces) *algebraic*. So if we say that M is an algebraic $\star$-object, we mean a set, R-module or (commutative) group, ring resp. R-algebra - but not a topological space. Let us now begin with the first half: **inverse limits**. This are sometimes also called **projective limits** of simply **limits**.

(3.164) Definition:
Let $(I, \leq)$ be a fixed partially ordered set. We say that (M_i, μ_j^i) is an **inverse system** of $\star$-objects over I, iff the following four properties are satisfied

(1) $\forall\, i \in I$ we get: M_i is a $\star$-object

(2) $\forall\, i, j \in I$ with $i \leq j$ we get: $\mu_j^i : M_j \to M_i$ is a $\star$-morphism

(3) $\forall\, i \in I$ we get: $\mu_i^i : M_i \to M_i : x \mapsto x$ is the identity map on M_i

(4) $\forall\, i, j$ and $k \in I$ with $i \leq j$ and $j \leq k$ we get: $\mu_j^i \mu_k^j = \mu_k^i$

And in this case we define the **inverse limit** of the inverse system (M_i, μ_j^i) to be the set of all sequences (x_i) that always satisfy $x_i = \mu_j(x_i)$ for all $i \leq j \in I$. Formally, that is

$$\varprojlim (M_i,\, \mu_j^i) \;:=\; \left\{ (x_i) \in \prod_{i \in I} M_i \;\middle|\; \forall\, i \leq j \in I \,:\, x_i = \mu_j^i(x_i) \right\}$$

Clearly the inverse limit allows to define the **canonical projections** π_j for any $j \in I$, that map (x_i) to x_j. And from the construction of the inverse limit it is clear, that for any $i \leq j \in I$ we get $\mu_j^i \pi_j = \pi_i$, where

$$\pi_j \;:\; \varprojlim (M_i,\, \mu_j^i) \;\to\; M_j \;:\; (x_i) \;\mapsto\; x_j$$

Recall, that a **net** (which some authors refer to, as a **filtered set**) is a non-empty, partially ordered set $(I, \leq)$, such that for any two elements $i, j \in I$ there is an $k \in I$, such that $k \geq i$ and $k \geq j$. By induction it is clear, that thereby for any finite subset $\{\, i_1, \ldots, i_n \,\} \subseteq I$ there is some $k \in I$ such that $k \geq i_r$ for any $r \in 1 \ldots n$. At times we will require this additional property in this section, as in (v) below:

(3.165) Proposition: (viz. 772)

(i) If (G_i, γ_j^i) is an inverse system of (commutative) groups, over the partially ordered set $(I, \leq)$, then its inverse limit is a (commutative) group again, under the pointwise composition $(x_i)(y_i) := (x_i y_i)$. And its neutral element is given to be (e_i) where $e_i \in G_i$ are the respective neutral elements.

(ii) Fix a commutative ring $(R, +, \cdot)$. If (M_i, μ_j^i) is an inverse system of R-modules, over the partially ordered set $(I, \leq)$, then its inverse limit is an R-module again, under the pointwise addition $(x_i) + (y_i) := (x_i + y_i)$ and scalar multiplication $a(x_i) := (a x_i)$.

(iii) If (R_i, ϱ_j^i) is an inverse system of (commutative) rings, over the partially ordered set $(I, \leq)$, then its inverse limit is a (commutative) ring again, under the pointwise addition $(a_i) + (b_i) := (a_i + b_i)$ and multiplication $(a_i) \cdot (b_i) := (a_i \cdot b_i)$. And its unit element is given to be (1_i) where $1_i \in R_i$ are the respective unit elements.

(iv) Fix a commutative ring $(R, +, \cdot)$. If (A_i, α_j^i) is an inverse system of R-algebras, over the partially ordered set $(I, \leq)$, then its inverse limit is an R-algebra again, under the pointwise addition $(f_i) + (g_i) := (f_i + g_i)$, multiplication $(f_i) \cdot (g_i) := (f_i \cdot g_i)$ and scalar-multiplication $a(f_i) := (a f_i)$. And its unit element is given to be (1_i) where $1_i \in A_i$ are the respective unit elements.

(v) If (X_i, f_j^i) is an inverse system of topological spaces $(X_i, \mathcal{T}_i)$, over the net $(I, \leq)$, then its inverse limit becomes a topological space again: Let $X_\infty := \varprojlim (X_i, f_j^i)$ abbreviate the inverse limit. The topology on X_∞ is taken to be the coarsest topology, such that all the canonical projections $\pi_j : X_\infty \to X_j : (x_i) \mapsto x_i$ are continuous. This is called the **limit topology** of X_∞ and a base of this topology is given by

$$\mathcal{W} \;:=\; \left\{\, \pi_i^{-1}(U_i) \;\middle|\; i \in I,\; U_i \subseteq X_i \text{ open} \,\right\}$$

In this particular case we get a concrete description of this topology in the following terms: A set $C \subseteq X_\infty$ is closed if and only if there is a sequence of closed subsets $C_i \subseteq X_i$, such that

$$C \;=\; \bigcap_{i \in I} \pi_i^{-1}(C_i)$$

(3.166) Example:

(i) Fix any commutative ring $(R,+,\cdot)$ and the index set $I := \mathbb{N}$. For any $n \in \mathbb{N}$ we regard the ring $R_n := R[t]/t^nR[t]$. That is $R_0 = 0$, $R_1 = R$ and so on. For any $m \leq n \in \mathbb{N}$ we define the transition map (which is well defined, as $t^nR[t] \subseteq t^mR[t]$)

$$\tau_n^m \;:\; R_n \;\twoheadrightarrow\; R_m \;:\; f + t^nR[t] \;\mapsto\; f + t^mR[t]$$

Then the inverse limit of this inverse system is isomorphic to the ring of formal power series over R. That is the following map is an isomorphism of rings

$$\begin{array}{rcl} R[\![t]\!] & \xrightarrow{\sim} & \varprojlim (R_n, \tau_n^m) \\ \displaystyle\sum_{k=0}^{\infty} a_k t^k & \mapsto & \left(\displaystyle\sum_{k=0}^{n-1} a_k t^k + t^nR[t] \right) \end{array}$$

(ii) The example in (i) above is a special case of the following more general situation: Fix a commutative ring $(R,+,\cdot)$ and an ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$. Over the index set $I := \mathbb{N}$ again, let $R_n := R/\mathfrak{a}^n$. As for $m \leq n$ we have $\mathfrak{a}^n \subseteq \mathfrak{a}^n$ the following transition maps are well defined, again

$$\tau_n^m \;:\; R_n \;\twoheadrightarrow\; R_m \;:\; b + \mathfrak{a}^n \;\mapsto\; n + \mathfrak{a}^m$$

This becomes (i) by taking $R[t]$ for R and $tR[t]$ for $\mathfrak{a}$. The inverse limit of this inverse system of commutative rings is said to be the **$\mathfrak{a}$-adic completion** of R. It is usually denoted by

$$\widehat{R} \;:=\; \varprojlim (R_n, \tau_n^m)$$

If the intersection $\bigcap_n \mathfrak{a}^n = 0$ vanishes, where $n \in \mathbb{N}$, then it is immediate to see, that we find a monomorphism of rings from R into its completion, simply by taking

$$R \;\hookrightarrow\; \widehat{R} \;:\; b \;\mapsto\; (b + \mathfrak{a}^n)$$

(iii) The following example is a little minimalistic and artificial, but instructive: Consider any two commutative rings $(R,+,\cdot)$ and $(S,+,\cdot)$ and a homomorphism of rings $\varphi : R \to S$ between them. We get an inverse system of commutative rings over $I := \{1,2\}$ by taking $R_2 := R$, $R_1 := S$ and $\varphi_2^1 := \varphi$. Let L denote the inverse limit of this indirect system, then the elements of L are pairs $(a,b) \in R \times S$ where $b = \varphi(s)$. That is

$$L \;=\; \{\, (a, \varphi(a)) \mid a \in R \,\} \;\subseteq\; R \oplus S$$

Thus we see, that the canonical projection $\pi_2 : L \to S$ maps $\pi_2(a,\varphi(a)) = \varphi(a)$ and hence need not be surjective in general. It will be surjective, if φ is such, but even this will not be true, for general inverse limits.

(iv) If the index set I has a maximal element $m \in I$, that is $i \leq m$ for any $i \in I$, then the inverse limit will be isomorphic to M_m. Hereby π_m is a $\star$-morphism and its inverse morphism is given to be

$$M_m \xrightarrow{\sim} \varprojlim (M_i, \mu_j^i) \ : \ x \mapsto (\mu_m^i(x))$$

We now turn our attention to the dual notion: **direct limits**, which some authors also call **colimits**. While inverse limits have been in the opposite direction of the index set, direct limits will be in the direction of the index set. The constructions will only be little more complicated, but the properties will be surprisingly different. Inverse limits usually are better behaved, than direct limits.

(3.167) Definition: (viz. 773)
Let $(I, \leq)$ be a fixed net. We say that (M_i, μ_j^i) is a **direct system** of $\star$-objects over I, iff the following four properties are satisfied

(1) $\forall\, i \in I$ we get: M_i is a $\star$-object

(2) $\forall\, i, j \in I$ with $i \leq j$ we get: $\mu_i^j : M_i \to M_j$ is a $\star$-morphism

(3) $\forall\, i \in I$ we get: $\mu_i^i : M_i \to M_i : x \mapsto x$ is the identity map on M_i

(4) $\forall\, i, j$ and $k \in I$ with $i \leq j$ and $j \leq k$ we get: $\mu_j^k \mu_i^j = \mu_i^k$

And in this case we define the **direct limit** of the direct system (M_i, μ_i^j) to be the disjoint union of the M_i under a certain equivalence relation $\sim$. Formally we define:

$$\varinjlim (M_i, \mu_i^j) := \mathcal{M} \Big/ \sim \quad \text{where} \quad \mathcal{M} := \bigcup_{i \in i} \{\, i \,\} \times M_i$$
$$\text{and} \quad (i, x) \sim (j, y) \ :\Longleftrightarrow \ \exists\, k \geq i, j \ : \ \mu_i^k(x) = \mu_j^k(y)$$

Nota this definition encompasses $(i, x) \sim (j, \mu_i^j(x))$ for any $j \geq i$. And clearly the direct limit allows to define the **structure morphisms** ε_i for any $i \in I$, that map x_i to its equivalence class $[i, x_i]$. And from the construction of the direct limit it is clear, that for any $i \leq j \in I$ we get $\varepsilon_j \mu_i^j = \varepsilon_i$, where

$$\pi_i \ : \ M_i \to \varinjlim (M_i, \mu_i^j) \ : \ x_i \mapsto [i, x_i]$$

(3.168) Proposition: (viz. 773)

(i) If (G_i, γ_i^j) is an direct system of (commutative) groups, over the net $(I, \leq)$, then its direct limit is a (commutative) group again, under the following composition: Given $[i, x]$ and $[j, y]$ choose any $k \in I$ with $k \geq i, j$, then $[i, x][j, y] := [k, \gamma_i^k(x)\gamma_j^k(y)]$. And its neutral element is given to be $[i, e_i]$ where $e_i \in G_i$ is the respective neutral element and $i \in I$ is arbitrary.

(ii) Fix a commutative ring $(R, +, \cdot)$. If (M_i, μ_j^i) is an direct system of R-modules, over the net $(I, \leq)$, then its direct limit is an R-module again, under the following addition and scalar multiplication: Given $[i, x]$ and $[j, y]$ choose any $k \in I$ with $k \geq i, j$, then $[i, x] + [j, y] := [k, \mu_i^k(x) + \mu_j^k(x)]$. And given $a \in R$ define $a[i, x] := [i, ax]$.

(iii) If (R_i, ϱ_j^i) is an inverse system of (commutative) rings, over the net $(I, \leq)$, then its direct limit is a (commutative) ring again, under the following addition and multiplication: Given $[i,a]$ and $[j,a]$ choose any $k \in I$ with $k \geq i, j$, then $[i,a] + [j,b] := [k, \varrho_i^k(a) + \varrho_j^k(b)]$ and likewise $[i,a] \cdot [j,b] := [k, \varrho_i^k(a) \cdot \varrho_j^k(b)]$. And its unit element is given to be $[i,1_i]$ where $1_i \in R_i$ is the respective unit element and $i \in I$ is arbitrary.

(iv) Fix a commutative ring $(R,+,\cdot)$. If (A_i, α_j^i) is a direct system of R-algebras, over the net $(I,\leq)$, then its direct limit is an R-algebra again, under the following addition and multiplication: Given $[i,f]$ and $[j,g]$ choose any $k \in I$ with $k \geq i, j$, then $[i,f] + [j,g] := [k, \alpha_i^k(f) + \alpha_j^k(g)]$ and likewise $[i,f] \cdot [j,g] := [k, \alpha_i^k(f) \cdot \alpha_j^k(g)]$. And its unit element is given to be $[i,1_i]$ where $1_i \in R_i$ is the respective unit element and $i \in I$ is arbitrary.

(v) If (X_i, f_i^j) is a direct system of topological spaces $(X_i, \mathcal{T}_i)$, over the net $(I,\leq)$, then its direct limit becomes a topological space again: Let $X_\infty := \varprojlim (X_i, f_j^i)$ abbreviate the direct limit. The topology on X_∞ is taken to be the coarsest topology, such that all the structure morphisms are continuous $\varepsilon_i : X_i \to X_\infty : x_i \mapsto [i,x_i]$. This is called the **limit topology** of X_∞ again and (by definition) a subset $U \subseteq X_\infty$ is open, if and only if

$$U \subseteq X_\infty \text{ open} \quad :\Longleftrightarrow \quad \forall\, i \in I : \varepsilon_i^{-1}(U) \subseteq X_i \text{ open}$$

(3.169) Proposition: (viz. 775)
Let (M_i, μ_i^j) be a direct system of $\star$-objects over the net $(I,\leq)$ and abbreviate its direct limit by M_∞. Then for any $i \in I$ the structure morphism $\varepsilon_i : M_i \to M_\infty$ is a $\star$-morphism. And if all of the transition maps μ_i^j are injective, then so are the ε_i.
In the case of topological spaces we also get the following statement: If all of the transition maps μ_i^j are open maps, then so are the structure morphisms ε_i.

(3.170) Example: (viz. 776)

(i) Let us consider our minimalistic example in the context of direct limits: Consider any two commutative rings $(R,+,\cdot)$ and $(S,+,\cdot)$ and a homomorphism of rings $\varphi : R \to S$ between them. We get a direct system of commutative rings over $I := \{1,2\}$ by taking $R_1 := R$, $R_2 := S$ and $\varphi_1^2 := \varphi$. Let L denote the direct limit of this indirect system, then the elements of L are either $[1,a]$ for some $a \in R$ or $[2,f]$ for some $f \in S$. Thereby $[1,a] = [2,f]$ iff $f = \varphi(a)$. Thus all the elements of R are absorbed in L in the form $[2,\varphi(a)]$. Hence it is not much of a surprise, that

$$\varepsilon_2 \,:\, S \xrightarrow{\sim} L \,:\, f \mapsto [2,f]$$

is an isomorphism of rings. However ε_1 need not be injective, in fact $[1,a] = [1,b]$ is true, iff $\varphi(a) = \varphi(b)$, so the injectivity of ε_1 stands or falls with the injectivity of φ.

(ii) If the index set I has a maximal element $m \in I$, that is $i \leq m$ for any $i \in I$, then the direct limit will be isomorphic to M_m. Hereby ε_m is a $\star$-morphism and its inverse morphism is given to be

$$\varinjlim (M_i,\, \mu_i^j) \xrightarrow{\sim} \,:\, [i,x] \mapsto \mu_i^m(x)$$

(3.171) Example: (viz. 776)
The following example will build up on *Shifting Ideals in polynomial Rings* in section 8.2. Consider any ascending chain of index sets $I_0 \subseteq I_1 \subseteq I_2 \subseteq \ldots$ and denote the union of all these sets by

$$I_\infty \;:=\; \bigcup_{n\in\mathbb{N}} I_n$$

Now, for any $n \in \mathbb{N}\cup\{\infty\}$ we abbreviate $R[n] := R[I_n] = R[t_i \mid i \in I_n]$ the polynomial ring in the variables t_i, where i runs in I_n. In particular, for any $m \leq n \in \mathbb{N}\cup\{\infty\}$ we have the canonical embeddings, which we will denote by

$$\iota_m^n \;:\; R[m] \;\hookrightarrow\; R[n] \;:\; f \mapsto f\,1_{R[n]}$$

Then $(R[n], \iota_m^n)$ is a directed system of rings over $\mathbb{N}$, and the direct limit of this system is isomorphic to $R[\infty]$, under the following isomorphism

$$\varinjlim (R[n],\, \iota_m^n) \;\xrightarrow{\sim}\; R[\infty] \;:\; [n,a] \mapsto \iota_n^\infty(a)$$

The inverse homomorphism is given to be $f \mapsto [n, \check{f}]$, where $n \in \mathbb{N}$ is taken in such a way that there is some $\check{f} \in R[n]$ satisfying $f = \iota_n^\infty(\check{f})$. This is possible, due to (8.15.(i)).

(3.172) Proposition: (viz. 777)
Let $(R,+,\cdot)$ be a commutative ring and (M_i, μ_i^j) be a direct system of R-modules over the net $(I,\leq)$. Denote its direct limit by M_∞ and let $\varepsilon_i : M_i \to M_\infty$ be the structural morphisms. Finally, for any $i \in I$, let $X_i \subseteq M_i$ be an arbitrary subset and denote

$$X_\infty \;:=\; \bigcup_{i\in I} \varepsilon_i(X_i) \quad\subseteq\quad M_\infty$$

(i) If for any $i \in I$ the set X_i generates M_i as an R-module, then X_∞ generates M_∞ as an R-module.

(ii) If (1) for any $i \in I$ the set X_i is R-linearly independent and (2) for any $i \leq j \in I$ we have $\mu_i^j(X_i) \subseteq X_j$, then X_∞ is R-linearly independent again.

(iii) If (1) for any $i \in I$ the set X_i is an R-basis of M_i and (2) for any $i \leq j \in I$ we have $\mu_i^j(X_i) \subseteq X_j$, then X_∞ is an R-basis of M_∞ again.

(3.173) Lemma: (viz. 778)

(i) *Universal Property of the inverse Limit*: Let (M_i, μ_i^j) be an inverse system of $\star$-objects over the partially ordered set $(I,\leq)$. Denote its inverse limit by M_∞ and let $\pi_i : M_\infty \to M_i$ be the canonical projections. Also consider a system (L, λ_i) satisfying the following properties

(1) L is a $\star$-object

(2) $\forall\, i \in I$ we get: $\lambda_i : L \to M_i$ is a $\star$-morphism

(3) $\forall\, i,j \in I$ with $i \leq j$ we get: $\lambda_i = \mu_j^i \lambda_j$

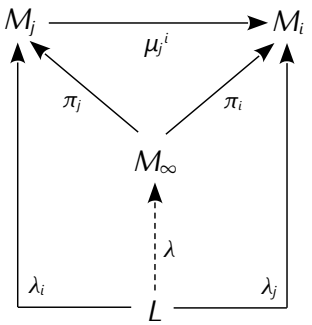
(4) Specifically in the case of topological spaces, we require $(I,\leq)$ to be a net.

Then there is a uniquely determined $\star$-morphism $\lambda : L \to M_\infty$ such that for any $i \in I$ we have the commutative diagram: $\lambda_i = \pi_i \lambda$ and this is given to be $\lambda(\ell) := (\mu_i(\ell))$.

(ii) *Universal Property of the direct Limit*: Let (M_i, μ_i^j) be a direct system of $\star$-objects over the net $(I, \leq)$. Denote its direct limit by M_∞ and let $\varepsilon_i : M_i \to M_\infty$ be the structure morphisms. Also consider a system (L, λ_i) satisfying the following properties

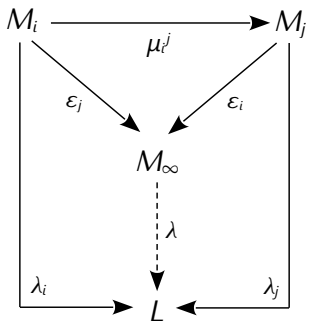
(1) L is a $\star$-object

(2) $\forall\, i \in I$ we get: $\lambda_i : M_i \to L$ is a $\star$-morphism



(3) $\forall\, i, j \in I$ with $i \leq j$ we get: $\lambda_i = \lambda_j \mu_i^j$

(4) Specifically in the case of topological spaces, we require a fourth property: For any i, $j \in I$ with $i \leq j$ we need the transition morphism μ_i^j to be an open map.



Then there is a uniquely determined $\star$-morphism $\lambda : M_\infty \to L$ such that for any $i \in I$ we have the commutative diagram: $\lambda_i = \lambda \varepsilon_i$ and this is given to be $\lambda([i, x]) := \mu_i(x)$.

(3.174) Remark:
The following diagrams depict the situation of the universal properties of the inverse resp. direct limits. A pair (L, φ_i) satisfying the respective properties (1) to (3) (even (4) for topological spaces) is occasionally said to be a *target*. Then by construction the inverse limit (M_∞, π_i) resp. the direct limit $(M_\infty, \varepsilon_i)$ are targets, themselves. The inverse limit is said to be an *attracting target*, whereas the direct limit is said to be a *repulsing target*. This refers to the direction of the morphism λ. And these notions stand to reason, if we take a look at the respective diagrams involved:

universal property of the inverse limit

universal property of the direct limit

(3.175) Corollary: (viz. 779)
This corollary holds for the following kinds $\star$-objects: Sets, commutative groups, commutative rings, any R-modules and commutative R-algebras (where as always $(R, +, \cdot)$ is any commutative ring). It need not hold true for non-commutative groups, rings and algebras or topological spaces.

(i) Let (M_i, μ_i^j) be an inverse system of $\star$-objects over the partially ordered set $(I, \leq)$ and fix another $\star$-object L, of the same kind. Then $H_i := \hom(L, M_i)$ is another $\star$-object, under the point-wise operations. And for any $i \leq j \in I$ we also get a $\star$-morphism, by

$$(\mu_j^i)_* \,:\, H_j \,\to\, H_i \,:\, \psi \,\mapsto\, \mu_i^j \psi$$

Thereby $(H_i, (\mu_j^i)_*)$ becomes an inverse system of $\star$-objects, over the same partially ordered set $(I, \leq)$. Let us abbreviate their inverse limits by

$$\begin{aligned} M_\infty &:= \varprojlim \left(M_i, \mu_j^i \right) \\ H_\infty &:= \varprojlim \left(H_i, (\mu_j^i)_* \right) \end{aligned}$$

As usual let $\pi_i : M_\infty \to M_i$ be the canonical projections of the inverse limit. Then we obtain a $\star$-isomorphism between the $\star$-homomorphisms from L to the inverse limit and the inverse limit of the $\star$-homomorphisms from L. And this isomorphism is given to be

$$\begin{array}{rcl} \hom(L, M_\infty) & \xrightarrow{\sim} & H_\infty \\ \psi & \mapsto & (\pi_i \psi) \\ (u \mapsto (\psi_i(u))) & \leftarrow\!\shortmid & (\psi_i) \end{array}$$

(ii) Let (M_i, μ_i^j) be a directed system of $\star$-objects over the net $(I, \leq)$ and fix another $\star$-object N, of the same kind. Then $H_i := \hom(M_i, N)$ is another $\star$-object, under the point-wise operations. And for any $i \leq j \in I$ we also get a $\star$-morphism, by

$$(\mu_i^j)^* \ : \ H_j \ \to \ H_i \ : \ \psi \mapsto \psi \mu_i^j$$

Thereby $(H_i, (\mu_i^j)^*)$ becomes another inverse system of $\star$-objects, over the same net $(I, \leq)$. Let us abbreviate their direct resp. inverse limits by

$$\begin{aligned} M_\infty &:= \varinjlim \left(M_i, \mu_i^j \right) \\ H_\infty &:= \varprojlim \left(H_i, (\mu_i^j)^* \right) \end{aligned}$$

As usual let $\varepsilon_i : M_i \to M_\infty$ be the structural morphisms of the direct limit. Then we obtain a $\star$-isomorphism between the $\star$-homomorphisms from the direct limit to N and the inverse limit of the $\star$-homomorphisms to N. And this isomorphism is given to be

$$\begin{array}{rcl} \hom(M_\infty, N) & \xrightarrow{\sim} & H_\infty \\ \psi & \mapsto & (\psi \varepsilon_i) \\ ([i, x] \mapsto \psi_i(x)) & \leftarrow\!\shortmid & (\psi_i) \end{array}$$

(3.176) Remark:
It will not have escaped your notice, that we only discussed two of the four possible combinations of homomorphisms and limits in (3.175). And in these two cases we took the indirect limit of the homomorphisms. If (M_i, φ_i^j) is a directed set of of $\star$-objects, then (by the universal property of the direct limit), we still find the following $\star$-morphism. Being a bit sloppy in our notation, we get

$$\varinjlim \hom(L, M_i) \ \to \ \hom(L, \varinjlim M_i) \ : \ [i, \psi] \ \mapsto \ \varepsilon_i \psi$$

where ε_i is the structural morphism of $\varinjlim M_i$ again. Alas, in general this $\star$-morphism need not be an isomorphism. In fact this is the case, if and only if L is finitely presented. Likewise, if (M_i, φ_j^i) is an inverse system of $\star$-objects, and π_i are the canonical projections of $\varprojlim M_i$, then (by the universal property of the direct limit), we find the following $\star$-morphism, again

$$\varinjlim \hom(M_i, N) \ \to \ \hom(\varprojlim M_i, N) \ : \ [i, \psi] \ \mapsto \ \psi\pi_i$$

(3.177) Definition: (viz. 781)

(i) Let (M_i, μ_j^i) and (N_i, ν_j^i) be inverse systems of $\star$-objects, over the same partially ordered set $(I, \leq)$ and let M_∞ and N_∞ be the respective inverse limits. Then an I-tuple (φ_i) is said to be **$\star$-system-morphism**, iff it satisfies both of the following properties

(1) For any $i \in I$ we find $\varphi_i : M_i \to N_i$ to be a $\star$-morphism

(2) For any $i \leq j \in I$ we have the commutative diagram $\varphi_i \mu_j^i = \nu_j^i \varphi_j$

In this case we find a $\star$-morphism $\varphi_\infty : M_\infty \to N_\infty$ by letting $(x_i) \mapsto (\varphi_i(x_i))$. And we denote this morphism by $\varprojlim (\varphi_i)$. For the $\star$-system-morphism itself, we will write

$$(\varphi_i) \ : \ (M_i, \mu_j^i) \ \to \ (N_i, \nu_j^i)$$

(ii) Let (M_i, μ_j^i) and (N_i, ν_j^i) be direct systems of $\star$-objects, over the same net $(I, \leq)$ and let M_∞ and N_∞ be the respective direct limits. Then an I-tuple (φ_i) is said to be **$\star$-system-morphism**, iff it satisfies both of the following properties (1) and (2)

(1) For any $i \in I$ we find $\varphi_i : M_i \to N_i$ to be a $\star$-morphism

(2) For any $i \leq j \in I$ we have the commutative diagram $\varphi_i \mu_j^i = \nu_j^i \varphi_j$

(3) Specifically in case of topological spaces, we also assume, that for any $i \leq j \in I$ the transition map $\nu_i^j : N_i \to N_j$ not only is continuous, but also is open.

In this case we find a well-defined $\star$-morphism $\varphi_\infty : M_\infty \to N_\infty$ by letting $[i, x] \mapsto [i, \varphi_i(x)]$. And we denote this morphism by $\varprojlim (\varphi_i)$. For the $\star$-system-morphism itself, we will write

$$(\varphi_i) \ : \ (M_i, \mu_i^j) \ \to \ (N_i, \nu_i^j)$$

(3.178) Proposition: (viz. 782)

(i) *Inverse limits of modules are left-exact*: Fix any commutative ring $(R, +, \cdot)$ and let (L_i, λ_j^i), (M_i, μ_j^i) and (N_i, ν_j^i) be inverse systems of R-modules over the same partially ordered set $(I, \leq)$. Also consider $(\varphi_i) : (L_i, \lambda_j^i) \to (M_i, \mu_j^i)$ and $(\psi_i) : (M_i, \mu_j^i) \to (N_i, \nu_j^i)$ two R-module-system homomorphisms, such that for any $i \in I$ the chains

$$0 \ \to \ L_i \ \xrightarrow{\varphi_i} \ M_i \ \xrightarrow{\psi_i} \ N_i$$

are exact. Let L_∞, M_∞ and N_∞ be the respective inverse limits of the inverse systems and let φ_∞ and ψ_∞ be the respective inverse limits of the morphisms, as in (3.177.(i)). Then we find, that the following chain is exact, as well:

$$0 \;\to\; L_\infty \;\xrightarrow{\varphi_\infty}\; M_\infty \;\xrightarrow{\psi_\infty}\; N_\infty$$

(ii) *Direct limits of modules are exact*: Fix any commutative ring $(R, +, \cdot)$ and let (L_i, λ_i^j), (M_i, μ_i^j) and (N_i, ν_i^j) be direct systems of R-modules over the same net $(I, \leq)$. Also consider two R-module-system homomorphisms $(\varphi_i) : (L_i, \lambda_i^j) \to (M_i, \mu_i^j)$ and $(\psi_i) : (M_i, \mu_i^j) \to (N_i, \nu_i^j)$, such that for any $i \in I$ the chains

$$0 \;\to\; L_i \;\xrightarrow{\varphi_i}\; M_i \;\xrightarrow{\psi_i}\; N_i \;\to\; 0$$

are exact. Let L_∞, M_∞ and N_∞ be the respective direct limits of the direct systems and let φ_∞ and ψ_∞ be the respective direct limits of the morphisms, as in (3.177.(ii)). Then we find, that the following chain is exact, as well:

$$0 \;\to\; L_\infty \;\xrightarrow{\varphi_\infty}\; M_\infty \;\xrightarrow{\psi_\infty}\; N_\infty \;\to\; 0$$

Pro: completion is exact Thm: spec of direct limit of rings is inverse limit of specs

Chapter 4

Linear Algebra

4.1 Matrix Algebra

Matrices serve two purposes: First of all they can represent systems of linear equations. And secondly (by fixing ordered bases) they can be used to represent homomorphisms between free modules. Using matrices these concepts are interlocked: The set of solutions is the kernel of the homomorphism (resp. an affine shift of the kernel in case of an inhomogeneous equation).
Also matrices provide a method of keeping track of the manipulations of a system of linear equations - the elementary matrices. Hence the algorithm how to solve a system of linear equations (Gauss-Algorithm) can be expressed in terms of matrices. This ultimately leads to a criterion whether a system of linear equations is (unambiguously) solvable - the determinant. So, as a first step, let us introduce the notion of a matrix and define a bunch of operations on matrices, that will be used later on.

(4.1) Definition:
Let $(R, +, \cdot)$ be any ring and fix a natural number $1 \leq n \in \mathbb{N}$. As before we will concern ourselves with the set R^n of n-tuples over R. Recall that this is given to be

$$R^n \;:=\; \{\, (x_1, \ldots, x_n) \mid x_1, \ldots, x_n \in R \,\}$$

In linear algebra it is customary (and occasionally useful) to write the n-tuple $x = (x_1, \ldots, x_n)$ in vertical order as well, that is we use two ways of denoting an n-tuple

$$(x_1, \ldots, x_n) \;=\; \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix}$$

We already turned R^n into an R-algebra by establishing the point-wise operations on R^n, let us recall this: Given any $x = (x_1, \ldots, x_n)$, $y = (y_1, \ldots, y_n) \in R^n$ and any $a \in R$ we have defined the operations

$$\begin{aligned} (x_1, \ldots, x_n) + (y_1, \ldots, y_n) &:= (x_1 + y_1, \ldots, x_n + y_n) \\ (x_1, \ldots, x_n) \cdot (y_1, \ldots, y_n) &:= (x_1 \cdot y_1, \ldots, x_n \cdot y_n) \\ a(x_1, \ldots, x_n) &:= (ax_1, \ldots, ax_n) \end{aligned}$$

As a new operation on R^n we define the **scalar product** (do not confuse this with the *scalar multiplication*) $R^n \times R^n \to R : (x,y) \mapsto \langle x,y\rangle$ which is defined to be (as always $x = (x_1,\dots,x_n)$ and $y = (y_1,\dots,y_n)$)

$$\langle x,y\rangle \;:=\; \sum_{i=1}^{n} x_i\, y_i$$

Finally we need to fix an easy notation for the canonical projections $\pi_i : R^n \to R : x \mapsto x_i$ of the product R^n. Recall that the π_i are R-algebra homomorphisms. Given any $i \in 1\dots n$ we denote

$$[x]_i \;:=\; x_i \quad \text{where} \quad x \;=\; (x_1,\dots,x_n)$$

(4.2) Remark:

(i) There are a multitude of ways how to embed $R \hookrightarrow R^n$ as a subalgebra. The most reasonable one (due to its symmetry) is to interpret $a \in R$ as the tuple $(a) = (a,\dots,a) \in R^n$. The advantage of this is evident: The multiplication then coincides with the scalar multiplication: That is we get $(a)\cdot x = ax$. Hence we fix

$$R \;\hookrightarrow\; R^n \;:\; a \mapsto (a) := (a,\dots,a)$$

(ii) Trivially R^n is a free module, having the Euclidean R-basis $\mathcal{E} = \{\, e_1,\dots,e_n \,\}$. Thereby the basis elements $e_j = (\delta_{i,j}) \in R^n$ are given to be (refer to (3.60) for more details)

$$\begin{aligned} e_1 &:= (1,0,0,\dots,0,0)\\ e_2 &:= (0,1,0,\dots,0,0)\\ &\;\;\vdots\\ e_n &:= (0,0,0,\dots,0,1) \end{aligned}$$

(iii) If R is a commutative ring, then clearly the scalar product on R^n has some neat computational properties: In fact it is a symmetric bilinear form of R^n: For any x, y, $z \in R^n$ and $a \in R$ we get

$$\begin{aligned} \langle ax+y,z\rangle &= a\langle x,z\rangle + \langle y,z\rangle \quad R\text{-linearity (in the 1st argument)}\\ \langle x,ay+z\rangle &= a\langle x,y\rangle + \langle y,z\rangle \quad R\text{-linearity (in the 2nd argument)}\\ \langle x,y\rangle &= \langle y,x\rangle \qquad\qquad \text{symmetry} \end{aligned}$$

In case R is not commutative only the R-linearity in the 1st argument is preserved. The other two properties are lost, in general. Prob all these properties are straightforward applications of the axioms of rings: $\langle ax+y,z\rangle = \sum_i (ax_i+y_i)z_i = \sum_i (ax_iz_i + y_iz_i) = a\sum_i x_iz_i + \sum_i y_iz_i = a\langle x,z\rangle + \langle y,z\rangle$. And the R-linearity in the second argument can be proved in complete analogy. The symmetry of the scalar product is evident: $\langle x,y\rangle = \sum_i x_iy_i = \sum_i y_ix_i = \langle y,x\rangle$.

(iv) Note that in general there is a difference between the scalar product $\langle x, y\rangle$ and an *inner product* $\langle x \mid y\rangle$. The latter will be defined in the case of $R = \mathbb{C}$ only and there is a subtle distinction between the scalar and inner products - the inner products uses complex conjugates. However this difference has far-reaching consequences: In contrast to the inner product, the scalar product over $R = \mathbb{C}$ is *not* positively definite. In fact we see that

$$\langle \begin{pmatrix} 1 \\ i \end{pmatrix}, \begin{pmatrix} 1 \\ i \end{pmatrix} \rangle \;=\; 1^2 + i^2 \;=\; 1 - 1 \;=\; 0$$

(4.3) Definition:
Let $(R, +, \cdot)$ be any ring again and fix two natural numbers $1 \leq m, n \in \mathbb{N}$. Then a $(m \times n)$-**matrix** is defined to be an n-tuple of m-tuples over R. Formally we will denote this set, by

$$\mathrm{mat}_{m,n}(R) \;:=\; (R^m)^n$$

A matrix usually is written as an m times n block of elements of R. That is if we have a number of n m-tuples $a_j = (a_{1,j}, \ldots, a_{m,j}) \in R^m$ where $j \in 1 \ldots n$ then we write the matrix $A = (a_1, \ldots, a_n)$ in the following form

$$\begin{pmatrix} a_{1,1} & a_{1,2} & \cdots & a_{1,n} \\ a_{2,1} & a_{2,2} & \cdots & a_{2,n} \\ \vdots & \vdots & & \vdots \\ a_{m,1} & a_{m,2} & \cdots & a_{m,n} \end{pmatrix} \;:=\; (a_{i,j}) \;:=\; A$$

That is the second index j of $A = (a_{i,j})$ designates the jth m-tuple a_j of A and this is written as the jth column of A. Complementary the first index i of $A = (a_{i,j})$ designates the ith component within the m-tuple a_j and these are written as the ith row of A.

We will later introduce some binary operations on matrices. To this end we need to introduce formal notations: Fix the $(m \times n)$-matrix $A = (a_{i,j})$ as above. Then - for any $i \in 1 \ldots n$ and any $j \in 1 \ldots n$ - we denote the (i, j)th **entry** of A, the i-th **row** of A and the j-th **column** of A respectively by

$$\begin{aligned} \mathrm{ent}_{i,j}(A) &:= a_{i,j} \in R \\ \mathrm{row}_i(A) &:= (a_{i,1}, a_{i,2}, \ldots, a_{i,n}) \in R^n \\ \mathrm{col}_j(A) &:= (a_{1,j}, a_{2,j}, \ldots, a_{m,j}) \in R^m \end{aligned}$$

Analogous to our notation for tuples we also denote $[A]_{i,j} := \mathrm{ent}_{i,j}(A) = a_{i,j}$. The **transpose** A^* of an $(m \times n)$-matrix $A = (a_{i,j})$ is defined to be the $(n \times m)$-matrix in which columns and rows are interchanged

$$A^* \;:=\; \begin{pmatrix} a_{1,1} & a_{2,1} & \cdots & a_{m,1} \\ a_{1,2} & a_{2,2} & \cdots & a_{m,2} \\ \vdots & \vdots & & \vdots \\ a_{1,n} & a_{2,n} & \cdots & a_{m,n} \end{pmatrix} \;\in\; \mathrm{mat}_{n,m}(R)$$

If $m = n$ then the rectangular block A of elements becomes a **square**. As this is an important special case we abbreviate our notation somewhat:

$$\mathsf{mat}_n(R) \;:=\; \mathsf{mat}_{n,n}(R) \;=\; (R^n)^n$$

A special case of such a matrix is a **diagonal matrix**. That is a square matrix $A = (a_{i,j})$ in which all entries off the diagonal are zero, i.e. $a_{i,j} = 0$ for any $i \neq j \in 1 \ldots n$. And if we are given n-elements $a_1, \ldots, a_n \in R$ then the diagonal matrix with the entries a_i on its diagonal is denoted by

$$\mathsf{dia}(a_1, \ldots, a_n) \;:=\; \begin{pmatrix} a_1 & 0 & \cdots & 0 & 0 \\ 0 & a_2 & & 0 & 0 \\ \vdots & & \ddots & & \vdots \\ 0 & 0 & & a_{n-1} & 0 \\ 0 & 0 & \cdots & 0 & a_n \end{pmatrix} \;\in\; \mathsf{mat}_n(R)$$

If $A \in \mathsf{mat}_n(R)$ is any square matrix, then we introduce the **trace** of A to be the sum of all its entries on the main diagonal, formally

$$\mathsf{tr}(A) \;:=\; \sum_{i=1}^{n} \mathsf{ent}_{i,i}(A)$$

For completeness purposes let us finally introduce a notation for the set of matrices of any size over R

$$\mathsf{Mat}(R) \;:=\; \bigcup_{m=1}^{\infty} \bigcup_{m=1}^{\infty} \mathsf{mat}_{m,n}(R)$$

(4.4) Remark:

(i) By construction an n-tuple $x = (x_1, x_2, \ldots, x_n) \in R^n$ is an $(n \times 1)$-matrix (which is sometimes also called a *column-vector*) which we denote by

$$x \;=\; \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix} \;\in\; \mathsf{mat}_{n,1}(R) \;=\; R^n$$

So n-tuples and and $(n \times 1)$-matrices really are the same thing, which is why it is perfectly legitimate to write tuples as column-vectors. The transpose x^* of x thereby is an $(1 \times n)$-matrix (which is sometimes called a *row-vector*)

$$x^* \;=\; \begin{pmatrix} x_1 & x_2 & \ldots & x_n \end{pmatrix} \;\in\; \mathsf{mat}_{1,n}(R)$$

Note that the row-vector is *not* the n-tuple $(x_1, x_2, \ldots, x_n)$ anymore! From an abstract point of view, it is an element of the dual-space of R^n (i.e. it is a linear map of the form $R^n \to R$). From a notational point of view it misses the commas, we use in tuples.

(ii) By definition of a $(m \times n)$-matrix, every n m-tuples $a_j = (a_{i,j}) \in R^m$ (where $j \in 1 \dots n$) determine a matrix $A := (a_1, \dots, a_n)$. To stress, that the a_j build up the columns of A we write

$$\begin{pmatrix} | & & | \\ a_1 & \cdots & a_n \\ | & & | \end{pmatrix} := (a_{i,j})$$

Conversely, if we are given m n-tuples $a_i = (a_{i,j}) \in R^n$ (where $i \in 1 \dots m$) we can build up a $(m \times n)$-matrix $A = (a_{i,j})$ by taking the a_i to be the rows of A. In this case we write

$$\begin{pmatrix} — & a_1 & — \\ & \vdots & \\ — & a_m & — \end{pmatrix} := (a_{i,j})$$

(ii) Recall that an $(m \times n)$-matrix $A = (a_{i,j})$ is defined to be an n-tuple of m-tuples of R. And the (i,j)th entry $a_{i,j}$ of A is the ith component of the jth component of A. So in a formal way that is

$$[A]_{i,j} = a_{i,j} = [[A]_j]_i$$

(4.5) Definition:
Let $(R, +, \cdot)$ be any ring again and consider the natural numbers $1 \leq m$ and $n \in \mathbb{N}$. By construction the set $\mathrm{mat}_{m,n}(R)$ of $(m \times n)$-matrices of R forms an R-module under the point-wise operations. That is: consider $a \in R$ and two $(m \times n)$-matrices $A = (a_{i,j})$ and $B = (b_{i,j}) \in \mathrm{mat}_{m,n}(R)$. Then we define the **addition** and **scalar-multiplication**

$$\begin{aligned} A + B &:= (a_{i,j} + b_{i,j}) \\ aB &:= (a\, b_{i,j}) \end{aligned}$$

Now consider another natural number $1 \leq l \in \mathbb{N}$ and suppose that $A \in \mathrm{mat}_{l,m}(R)$ is a $(l \times m)$-matrix, whereas $B \in \mathrm{mat}_{m,n}(R)$ is an $(m \times n)$-matrix. Then we can define the **matrix-multiplication** AB of A and B to be the following $(l \times n)$-matrix

$$AB := \Big(\langle \mathrm{row}_i(A), \mathrm{col}_k(B) \rangle\Big) = \left(\sum_{j=1}^{m} a_{i,j}\, b_{j,k}\right) \in \mathrm{mat}_{l,n}(R)$$

That is the (i,k)-th entry of AB is the i-th row of A multiplied with the k-th column of B. That is: If $a_i = \mathrm{row}_i(A) = (a_{i,1}, \dots, a_{i,m})$ is the i-th row of A and $b_k = \mathrm{col}_k(B) = (b_{1,k}, \dots, b_{m,k})$ is the k-th column of B, then the matrix-multiplication follows the scheme

$$\begin{pmatrix} — & a_1 & — \\ & \vdots & \\ — & a_l & — \end{pmatrix} \begin{pmatrix} | & & | \\ b_1 & \cdots & b_n \\ | & & | \end{pmatrix} = \Big(\langle a_i, b_k \rangle\Big)$$

A special case of this is the **matrix-vector** multiplication: Given an $(m \times n)$-matrix $A \in \mathrm{mat}_{m,n}(R)$ and an n-tuple $x \in R^n$ over R we obtain an m-tuple $Ax \in R^m$ by virtue of

$$Ax \;:=\; (\langle \mathrm{row}_1(A), x\rangle, \ldots, \langle \mathrm{row}_m(A), x\rangle) \;\in\; R^m$$

That is we use the rows of A to be multiplied with the tuple x. So if $a_i = \mathrm{row}_i(A) = (a_{i,1}, \ldots, a_{i,n})$ is the i-th row of A, then the matrix-vector multiplication can be pinned down in the more intuitive way

$$\begin{pmatrix} \text{—} & a_1 & \text{—} \\ & \vdots & \\ \text{—} & a_m & \text{—} \end{pmatrix} \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} \;=\; \begin{pmatrix} \langle a_1, x\rangle \\ \vdots \\ \langle a_n, x\rangle \end{pmatrix} \;\in\; R^m$$

(4.6) Remark:

(i) Let us reformulate the above definitions of addition, scalar multiplication and vector multiplication in terms of the entries of the resulting matrices. That is we take A, $B \in \mathrm{mat}_{m,n}(R)$, $a \in R$ and $x \in R^n$. Then for any $i \in 1 \ldots m$ and any $j \in 1 \ldots n$ we have

$$\begin{aligned} \mathrm{ent}_{i,j}(aA + B) &= a\,\mathrm{ent}_{i,j}(A) + \mathrm{ent}_{i,j}(B) \\ [Ax]_i &= \sum_{j=1}^{n} \mathrm{ent}_{i,j}(A)\;[x]_j \end{aligned}$$

And if $A \in \mathrm{mat}_{l,m}(R)$ and $B \in \mathrm{mat}_{m,n}(R)$ we can also reformulate the matrix multiplication for all the entries $i \in 1 \ldots l$ and $k \in 1 \ldots n$

$$\mathrm{ent}_{i,k}(AB) \;=\; \sum_{j=1}^{m} \mathrm{ent}_{i,j}(A)\,\mathrm{ent}_{j,k}(B)$$

(ii) If $x = (x_1, x_2, \ldots x_n)$ and $y = (y_1, y_2, \ldots y_n) \in R^n$ are n-tuples over R, then the matrix multiplication can be used to emulate the scalar product

$$x^* y \;=\; \sum_{j=1}^{n} x_j y_j \;=\; \langle x, y\rangle$$

(iii) If $A \in \mathrm{mat}_{m,n}(R)$ is an $(m \times n)$-matrix and $x = (x_1, x_2, \ldots, x_n) \in R^n$ is an n-tuple, then the matrix-vector multiplication yields the following linear combination of the columns of A

$$Ax \;=\; \sum_{j=1}^{n} \mathrm{col}_j(A) \cdot x_j \;\in\; R^m$$

Likewise, if $y = (y_1, y_2, \ldots, y_m) \in R^m$ is an m-tuple, then the matrix multiplication can also yield the following linear combination of the rows of A

$$y^* A \;=\; \sum_{i=1}^{m} y_i \cdot \mathrm{row}_i(A) \;\in\; R^n$$

(iv) Let us also reformulate the transposition $A \mapsto A^*$ of matrices in terms of the rows, columns and entries. Then it is clear that for any $A \in \mathrm{mat}_{m,n}(R)$ and any $i \in 1 \ldots m$, $j \in 1 \ldots n$ we get

$$\begin{aligned} \mathrm{ent}_{j,i}(A^*) &= \mathrm{ent}_{i,j}(A) \\ \mathrm{col}_i(A^*) &= \mathrm{row}_i(A) \\ \mathrm{row}_j(A^*) &= \mathrm{col}_j(A) \end{aligned}$$

Prob recall that $\mathrm{ent}_{j,i}(A^*) = \mathrm{ent}_{i,j}(A)$ is just the definition of the transpose A^*. And thus we find $\mathrm{col}_i(A^*) = (\mathrm{ent}_{1,i}(A^*), \ldots, \mathrm{ent}_{n,i}(A^*)) = (\mathrm{ent}_{i,1}(A), \ldots, \mathrm{ent}_{i,n}(A)) = \mathrm{row}_i(A)$. Likewise we compute $\mathrm{row}_j(A^*) = (\mathrm{ent}_{j,1}(A^*), \ldots, \mathrm{ent}_{j,m}(A^*)) = (\mathrm{ent}_{1,j}(A), \ldots, \mathrm{ent}_{m,j}(A)) = \mathrm{col}_j(A)$.

(v) If R is a commutative ring and $A \in \mathrm{mat}_{m,n}(R)$ is a matrix, then A gives rise to an R-module homomorphism of the following form, by vector-matrix multiplication

$$\varphi_A \ : \ R^n \to R^m \ : \ x \mapsto Ax$$

By abuse of notation we usually identify $\varphi_A = A$ here, but we will also see that all homomorphisms between finitely generated, free R-modules can be represented in this way - this will be the topic of section 4.4. Due to (iii) above the image of φ_A is generated by the columns of A, that is

$$\mathrm{im} \begin{pmatrix} | & & | \\ c_1 & \cdots & c_n \\ | & & | \end{pmatrix} \ = \ \mathrm{Lh}\{ c_1, \ldots, c_n \} \quad \leq_{\mathtt{m}} \quad R^m$$

Prob in a commutative ring R the scalar product $x \mapsto \langle r, x \rangle$ is R-linear for any $r \in R^n$, in particular for $r = \mathrm{row}_i(A)$. And as $x \mapsto Ax$ is the cartesian product of m-scalar products, φ_A is R-linear, too. Also, if $c_j := \mathrm{col}_j(A)$ is the j-th column of A, then we have $Ax = x_1c_1 + \ldots x_nc_n$ by (iii). That is the image of φ_A is precisely the linear hull of the c_j where $j \in 1 \ldots n$.

(vi) Note that the matrix-matrix multiplication AB is nothing but a matrix-vector multiplication Ab_k for all the column vectors b_k of B. I.e. given $A \in \mathrm{mat}_{l,m}(R)$ and $b_k \in R^m$ (where $k \in 1 \ldots n$) we have

$$A \begin{pmatrix} | & & | \\ b_1 & \cdots & b_m \\ | & & | \end{pmatrix} \ = \ \begin{pmatrix} | & & | \\ Ab_1 & \cdots & Ab_m \\ | & & | \end{pmatrix}$$

(vii) Suppose R is a commutative ring again and consider $A = \mathrm{mat}_{k,m}(R)$ and $B \in \mathrm{mat}_{m,n}(R)$. If for $i \in 1 \ldots k$ the i-th row of A is abbreviated by $a_i = \mathrm{row}_i(A) \in R^m$, then we can also rewrite a multiplication of B from the right as an operation of the transpose B^* on the rows of A

$$\begin{pmatrix} \text{---} & a_1 & \text{---} \\ & \vdots & \\ \text{---} & a_k & \text{---} \end{pmatrix} B \ = \ \begin{pmatrix} \text{---} & B^*a_1 & \text{---} \\ & \vdots & \\ \text{---} & B^*a_k & \text{---} \end{pmatrix}$$

Prob For any $r \in 1 \dots k$ and any $s \in 1 \dots n$ let us evaluate the (r,s)-entry of the matrix AB. By definition this is $[AB]_{r,s} = \langle a_i, \mathrm{col}_k(B) \rangle = \sum_j a_{r,j} b_{j,k}$. On the right hand side the (r,s)-th entry is the s-th component of $B^* a_r$ and hence $[B^* a_r]_s = \sum_j b^*_{s,j} [a_r]_j = \sum_j b_{j,s} a_{r,j}$. Since R is commutative both are equal.

(4.7) Example:
Let us take the integers $R = \mathbb{Z}$ as a base ring. Then we want to give an explicit example of a matrix multiplication, where $A \in \mathrm{mat}_{3,4}(\mathbb{Z})$ and $B \in \mathrm{mat}_{4,2}(\mathbb{Z})$ such that $AB \in \mathrm{mat}_{3,2}(\mathbb{Z})$. Our example will be

$$AB \;=\; \begin{pmatrix} -2 & 6 & 0 & 2 \\ 0 & 1 & 0 & 0 \\ 1 & 4 & 2 & -6 \end{pmatrix} \begin{pmatrix} 4 & 0 \\ -1 & 0 \\ 3 & 1 \\ 7 & 0 \end{pmatrix}$$

For the upper left entry of AB we compute $-2 \cdot 4 + 6 \cdot (-1) + 0 \cdot 3 + 2 \cdot 7 = 0$. Likewise for the lower left entry of AB (that is the third row and first column) we compute $1 \cdot 4 + 4 \cdot (-1) + 2 \cdot 3 - 6 \cdot 7 = -36$. Altogether we find

$$AB \;=\; \begin{pmatrix} 0 & 0 \\ -1 & 0 \\ -36 & 2 \end{pmatrix}$$

We installed some noteworthy specialities in this example: First of all we see that $\mathrm{col}_2(B) = e_3 \in \mathbb{Z}^4$. And this explains why the the second column of AB is just a copy of the third column of A

$$\mathrm{col}_2(AB) \;=\; A\,\mathrm{col}_2(B) \;=\; A\,e_3 \;=\; \mathrm{col}_3(A)$$

Likewise we have $\mathrm{row}_2(A) = e_2 \in \mathbb{Z}^4$ and that's why the the second row of AB is just another copy of the second row of B, since

$$\mathrm{row}_2(AB) \;=\; B^*\,\mathrm{row}_2(A) \;=\; B^*\,e_2 \;=\; \mathrm{col}_2(B^*) \;=\; \mathrm{row}_2(B)$$

And lastly we see that AB has an entire zero-row $\mathrm{row}_1(AB) = 0$. E.g. for the $(1,2)$-entry (= upper left) of AB this means that

$$\mathrm{ent}_{1,2}(AB) \;=\; \langle \mathrm{row}_1(A), \mathrm{col}_2(B) \rangle \;=\; 0$$

Geometrically speaking this means that $\mathrm{row}_1(A)$ and $\mathrm{col}_2(B) \in \mathbb{Z}^4$ are perpendicular. But this also warns us, that the product AB may vanish, even if A and B are non-zero.

(4.8) Proposition: (viz. 1013)
Consider any ring $(R, +, \cdot)$ and fix the natural numbers $1 \leq l$, m, n, p and $q \in \mathbb{N}$. Then all of the following statements hold true

(i) The set $\mathrm{mat}_{m,n}(R)$ of $(m \times n)$-matrices over R is an R-module under the addition and scalar multiplication of matrices, as defined in (4.5). The zero-element thereby is the *zero-matrix*

$$0 \;=\; (0) \;=\; \begin{pmatrix} 0 & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & 0 \end{pmatrix}$$

In fact $\mathrm{mat}_{m,n}(R)$ is a free R-module of rank mn. We can easily provide the *Euclidean* R-basis $\mathcal{E} := \{ E_{r,s} \mid r \in 1 \ldots m, s \in 1 \ldots n \}$ of $\mathrm{mat}_{m,n}(R)$. Thereby $E_{r,s}$ is the $(m \times n)$ matrix that is entirely 0, except its (r,s)th entry, which is 1. Formally

$$E_{r,s} \;:=\; \left(\delta_{i,r}\, \delta_{j,s}\right) \;\in\; \mathrm{mat}_{m,n}(R)$$

(ii) The multiplication of matrices is associative and distributive (but in general not commutative). Suppose that A, B and C are matrices of compatible sizes, then

$$\begin{aligned} (AB)C &= A(BC) \\ A(B+C) &= AB + AC \\ (A+B)C &= AC + BC \end{aligned}$$

Note: to be of compatible sizes means $A \in \mathrm{mat}_{m,n}(R)$, $B \in \mathrm{mat}_{n,p}(R)$ and $C \in \mathrm{mat}_{p,q}(R)$ for the associativity, $A \in \mathrm{mat}_{l,m}(R)$, B and $C \in \mathrm{mat}_{m,n}(R)$ for the left-distributivity and A, $B \in \mathrm{mat}_{l,m}(R)$ and $C \in \mathrm{mat}_{m,n}(R)$ for the right-distributivity.

(iii) In particular the set $\mathrm{mat}_n(R)$ of $(n \times n)$-matrices over R is an R-algebra under the addition, scalar-multiplication and matrix-multiplication of matrices as defined in (4.5). Its unit-element is the *identity-matrix*

$$\mathbb{1}_n \;=\; (\delta_{i,j}) \;=\; \begin{pmatrix} 1 & 0 & \cdots & 0 \\ 0 & 1 & & 0 \\ \vdots & & \ddots & \\ 0 & 0 & & 1 \end{pmatrix}$$

(iv) In particular - according to (iii) - $\mathrm{mat}_n(R)$ is a ring, however it need not be commutative, even if R is commutative. An invertible element of this ring is said to be an **invertible matrix**. I.e. $A \in \mathrm{mat}_n(R)$ is invertible iff there is some $B \in \mathrm{mat}_n(R)$ such that

$$AB \;=\; \mathbb{1}_n \;=\; BA$$

And in this case B is uniquely determined by A (as this is true for any ring) and (as in general rings before) we denote the **inverse matrix** of A by $A^{-1} := B$.

(v) Recall the definition of the center $\mathrm{cen}(R)$ of a ring R to be the sub-ring of all elements that commute with all other elements, that is $\mathrm{cen}(R) = \{\, a \in R \mid \forall\, b \in R : ab = ba \,\}$. Then the center of $\mathrm{mat}_n(R)$ is just the center of R embedded as diagonal matrices $\mathrm{cen}\left(\mathrm{mat}_n(R)\right) = \mathrm{cen}(R)\mathbb{1}_n$ or more explicitly:

$$\mathrm{cen}\left(\mathrm{mat}_n(R)\right) \;=\; \left\{ \begin{pmatrix} a & 0 & \cdots & 0 \\ 0 & a & & 0 \\ \vdots & & \ddots & \\ 0 & 0 & & a \end{pmatrix} \;\middle|\; a \in \mathrm{cen}(R) \right\}$$

(vi) If R is a commutative ring and A, $B \in \mathrm{mat}_n(R)$ are square matrices over R, then the trace is invariant under commuting A and B

$$\mathrm{tr}(AB) \;=\; \mathrm{tr}(BA)$$

(vii) If R is a commutative ring, then any matrix $A \in \mathrm{mat}_{m,n}(R)$ induces a homomorphism of R-modules $\varphi_A : R^n \to R^n$ by using the matrix-vector multiplication $\varphi_A(x) := Ax$. And thereby we find the following, well-defined, isomorphism of R-modules

$$\mathrm{mat}_{m,n}(R) \;\xrightarrow{\sim}\; \mathrm{mhom}(R^n, R^m) \;:\; A \;\mapsto\; \varphi_A$$

(viii) The transposition $A \mapsto A^*$ of matrices is an isomorphism of R-modules $\mathrm{mat}_{m,n}(R) \xrightarrow{\sim} \mathrm{mat}_{n,m}(R)$. In particular for any $a \in R$ and any A, $B \in \mathrm{mat}_{m,n}(R)$ we have

$$(aA + B)^* \;=\; aA^* + B^*$$

(ix) If R is commutative, then the transposition of matrices swaps the order of matrix-multiplications. That is given any matrices $A \in \mathrm{mat}_{l,m}(R)$ and $B \in \mathrm{mat}_{m,n}(R)$ we find that

$$(AB)^* \;=\; B^*A^*$$

(ix) If R is commutative then taking inverses in $\mathrm{mat}_n(R)$ commutes with the transposition. To be precise: If $A \in \mathrm{mat}_n(R)$ is a square matrix, then A is invertible, if and only if A^* is invertible. And in this case the inverse of A^* is given to be

$$(A^*)^{-1} \;=\; \left(A^{-1}\right)^*$$

(xi) If R is a commutative ring, then for any vectors $x \in R^n$, $y \in R^m$ and any matrix $A \in \mathrm{mat}_{m,n}(R)$ we get the following identity in R

$$\langle Ax, y \rangle \;=\; \langle x, A^*y \rangle$$

(4.9) Definition: Block Notation

Let $(R, +, \cdot)$ be any ring, $1 \leq r, s \in \mathbb{N}$ and for any $p \in 1 \dots r$ consider some $1 \leq m(p) \in \mathbb{N}$. Likewise for any $q \in 1 \dots s$ let $1 \leq n(q) \in \mathbb{N}$, as well. Finally consider a matrix $A^{p,q} \in \mathrm{mat}_{m(p),n(q)}(R)$ for any $p \in 1 \dots r$ and $q \in 1 \dots s$. Now denote $m := m(1) + m(2) + \dots + m(r)$ and $n := n(1) + n(2) + \dots n(s)$. Then we define the **block matrix**

$$\begin{pmatrix} A^{1,1} & A^{1,2} & \dots & A^{1,s} \\ A^{2,1} & A^{2,2} & \dots & A^{2,s} \\ \vdots & \vdots & & \vdots \\ A^{r,1} & A^{r,2} & \dots & A^{r,s} \end{pmatrix} \in \mathrm{mat}_{m,n}(R)$$

in the following way: For any $p \in 1 \dots r$ and any $q \in 1 \dots s$ let $A^{p,q}$ have the entries $A^{p,q} = (a^{p,q}_{i,j})$ where $i \in 1 \dots m(p)$ and $j \in 1 \dots n(q)$. Then the above block matrix is set to be:

$$\begin{pmatrix}
a^{1,1}_{1,1} & \dots & a^{1,1}_{1,n(1)} & a^{1,2}_{1,1} & \dots & a^{1,2}_{1,n(2)} & \dots & a^{1,s}_{1,1} & \dots & a^{1,s}_{1,n(s)} \\
\vdots & & \vdots & \vdots & & \vdots & & \vdots & & \vdots \\
a^{1,1}_{m(1),1} & \dots & a^{1,1}_{m(1),n(1)} & a^{1,2}_{m(1),1} & \dots & a^{1,2}_{m(1),n(2)} & \dots & a^{1,s}_{m(1),1} & \dots & a^{1,s}_{m(1),n(s)} \\
a^{2,1}_{1,1} & \dots & a^{2,1}_{1,n(1)} & a^{2,2}_{1,1} & \dots & a^{2,2}_{1,n(2)} & \dots & a^{2,s}_{1,1} & \dots & a^{2,s}_{,n(s)} \\
\vdots & & \vdots & \vdots & & \vdots & & \vdots & & \vdots \\
a^{2,1}_{m(2),1} & \dots & a^{2,1}_{m(2),n(1)} & a^{2,2}_{m(2),1} & \dots & a^{2,2}_{m(2),n(2)} & \dots & a^{2,s}_{m(2),1} & \dots & a^{2,s}_{m(2),n(s)} \\
\vdots & & \vdots & \vdots & & \vdots & & \vdots & & \vdots \\
a^{r,1}_{1,1} & \dots & a^{r,1}_{1,n(1)} & a^{r,2}_{1,1} & \dots & a^{r,2}_{1,n(2)} & \dots & a^{r,s}_{1,1} & \dots & a^{r,s}_{1,n(s)} \\
\vdots & & \vdots & \vdots & & \vdots & & \vdots & & \vdots \\
a^{r,1}_{m(r),1} & \dots & a^{r,1}_{m(r),n(1)} & a^{r,2}_{m(r),1} & \dots & a^{r,2}_{m(r),n(2)} & \dots & a^{r,s}_{m(r),1} & \dots & a^{r,s}_{m(r),n(s)}
\end{pmatrix}$$

An important special case is the following: Given $A = (a_{i,j}) \in \mathrm{mat}_{k,l}(R)$ and $B = (b_{i,j}) \in \mathrm{mat}_{m,n}(R)$ matrices of arbitrary size $1 \leq k, l, m$ and $n \in \mathbb{N}$. Then we define the **direct sum** of these to be the following $(k+m) \times (l+n)$ matrix over R: Let $0_{k,n} = 0 \in \mathrm{mat}_{k,n}(R)$ and $0_{m,l} = 0 \in \mathrm{mat}_{m,l}(R)$ be the zero-matrices of the respective size, then

$$A \oplus B := \begin{pmatrix} A & 0_{k,n} \\ 0_{m,l} & B \end{pmatrix} \in \mathrm{mat}_{k+m,l+n}(R)$$

Explicitly $A \oplus B$ can be written out in the entries of A and B as we did above. In this form $A \oplus B$ is just the following matrix

$$A \oplus B = \begin{pmatrix}
a_{1,1} & a_{1,2} & \dots & a_{1,l} & 0 & 0 & \dots & 0 \\
a_{2,1} & a_{2,2} & \dots & a_{2,l} & 0 & 0 & \dots & 0 \\
\vdots & \vdots & & \vdots & \vdots & \vdots & & \vdots \\
a_{k,1} & a_{k,2} & \dots & a_{k,l} & 0 & 0 & \dots & 0 \\
0 & 0 & \dots & 0 & b_{1,1} & b_{1,2} & \dots & b_{1,n} \\
0 & 0 & \dots & 0 & b_{2,1} & b_{2,2} & \dots & b_{2,n} \\
\vdots & \vdots & & \vdots & \vdots & \vdots & & \vdots \\
0 & 0 & \dots & 0 & b_{m,1} & b_{m,2} & \dots & b_{m,n}
\end{pmatrix}$$

In a more formal way, suitable for programming and maybe for explicit computations, the entries of the direct sum $A \oplus B$ of the matrices A and B can be given to be the following

$$A \oplus B \;=\; \Big(s_{i,j}\Big)_{\substack{i\in 1\ldots k+m\\ j\in 1\ldots l+n}} \text{ where } s_{i,j} := \begin{cases} a_{i,j} \text{ if } i \leq k \text{ and } j \leq l \\ b_{i-k,j-l} \text{ if } i > k \text{ and } j > l \\ 0 \text{ if else} \end{cases}$$

(4.10) Remark: (viz. 1017)
If you concentrate a little, you will see, that this block-notation agrees with the matrix multiplication, in the following sense: Let $(R, +, \cdot)$ be a ring and $1 \leq r, s, t \in \mathbb{N}$. We assume the following block matrices to be of compatible structure

$$A \;=\; \begin{pmatrix} A^{1,1} & A^{1,2} & \ldots & A^{1,s} \\ A^{2,1} & A^{2,2} & \ldots & A^{2,s} \\ \vdots & \vdots & & \vdots \\ A^{r,1} & A^{r,2} & \ldots & A^{r,s} \end{pmatrix} \;\in\; \mathrm{mat}_{l,m}(R)$$

$$B \;=\; \begin{pmatrix} B^{1,1} & B^{1,2} & \ldots & B^{1,t} \\ B^{2,1} & B^{2,2} & \ldots & B^{2,t} \\ \vdots & \vdots & & \vdots \\ B^{s,1} & B^{s,2} & \ldots & B^{s,t} \end{pmatrix} \;\in\; \mathrm{mat}_{m,n}(R)$$

That is $A^{i,j}$ is a $(l(i) \times m(j))$-matrix over R and $B^{j,k}$ is a $(m(j) \times n(k))$-matrix over R for the same $m(j)$. In other words the vertical borders in A are of the same sizes, as the horizontal borders of B. Then the product AB can be computed using the usual multiplication of matrices

$$AB \;=\; \begin{pmatrix} \sum_{j=1}^{s} A^{1,j}B^{j,1} & \ldots \sum_{j=1}^{s} A^{1,j}B^{j,t} \\ \vdots & \vdots \\ \sum_{j=1}^{s} A^{r,j}B^{j,1} & \ldots \sum_{j=1}^{s} A^{r,j}B^{j,1} \end{pmatrix} \;\in\; \mathrm{mat}_{l,n}(R)$$

This becomes clear, once you realize, that the u-th row of A and v-th column of B break down into a row u' along the sub-matrices $A^{i,j}$ and the v'-column along the sub-matrices $B^{j,k}$ where j runs from 1 to s. Hence the scalar product $\langle \mathrm{row}_u(A), \mathrm{col}_v(B)\rangle$ breaks down into the sum of s scalar products $\langle \mathrm{row}_{u'}(A^{i,j}), \mathrm{col}_{v'}(B^{j,k})\rangle$. Refer to the proof for details. In particular we have the following product of block matrices that is mostly used, when $A^{2,1} = 0$

$$\begin{pmatrix} A^{1,1} & A^{1,2} \\ A^{2,1} & A^{2,2} \end{pmatrix} \begin{pmatrix} B^{1,1} & B^{1,2} \\ B^{2,1} & B^{2,2} \end{pmatrix} \;=\; \begin{pmatrix} A^{1,1}B^{1,1} + A^{1,2}B^{2,1} & A^{1,1}B^{1,2} + A^{1,2}B^{2,2} \\ A^{2,1}B^{1,1} + A^{2,2}B^{2,1} & A^{2,1}B^{1,2} + A^{2,2}B^{2,2} \end{pmatrix}$$

(4.11) Corollary:
Let $(R,+,\cdot)$ be any ring, $1 \leq n \in \mathbb{N}$ and $e_k \in R^n$ be the Euclidean basis vectors again, i,e, $e_k = (\delta_{i,k})$. If now $A \in \mathrm{mat}_n(R)$ is an invertible matrix, then the columns of the inverse matrix A^{-1} are uniquely determined by the property $A\,\mathrm{col}_k(A^{-1}) = e_k$. That is, if for any $k \in 1 \ldots n$ the vector $x_k \in R^k$ is the solution of $Ax_k = e_k$, then

$$A^{-1} \;=\; \begin{pmatrix} | & & | \\ x_1 & \cdots & x_n \\ | & & | \end{pmatrix}$$

Prob Let $x_k := A^{-1}e_k$ then $Ax_k = AA^{-1}e_k = \mathbb{1}_n e_k = e_k$, i.e. x_k is the solution of $Ax_k = e_k$. Then by (4.6.(v)) A^{-1} maps the columns of $\mathbb{1}_n$ onto x_1 to x_n, that is we get the identity

$$A^{-1} \;=\; A^{-1}\mathbb{1}_n \;=\; A^{-1}\begin{pmatrix} | & & | \\ e_1 & \cdots & e_n \\ | & & | \end{pmatrix} \;=\; \begin{pmatrix} | & & | \\ A^{-1}e_1 & \cdots & A^{-1}e_n \\ | & & | \end{pmatrix} \;=\; \begin{pmatrix} | & & | \\ x_1 & \cdots & x_n \\ | & & | \end{pmatrix}$$

(4.12) Remark: $(\diamondsuit)$
The above corollary provides a first way of computing the inverse A^{-1} of a matrix $A \in \mathrm{mat}_n(R)$. All we have to do is solving the equations $Ax_k = e_k$ for the Euclidean vectors e_k e.g. by the Gaussian algorithm (4.29) or LU-decomposition. For practical computations over a commutative ring R it is best to do this for all n SLEs simultaneously. That is we start with $(A \mid \mathbb{1}_n)$ and regard this as a $(n \times 2n)$-matrix. Then try to bring this into the form $(\mathbb{1}_n \mid B)$ using elementary operations on the rows of $(A \mid B)$. Once we arrived at $(\mathbb{1}_n \mid B)$, we have found the inverse $A^{-1} = B$. The operations allowed, are

1. Interchange two rows of $(A \mid B)$.

2. Multiply one row of $(A \mid B)$ with a common factor $a \in R$.

3. Add or subtract one row of $(A \mid B)$ from another row.

Prob Operations on the rows are multiplications with a matrix S from the left (this will be the topic of the next section). So if we have $(SA \mid S\mathbb{1}_n) = (\mathbb{1}_n \mid B)$ then $B = S\mathbb{1}_n = S$ and hence $BA = SA = \mathbb{1}_n$. And as R is commutative (4.65) implies $AB = \mathbb{1}_n$, too, such that $A^{-1} = B$. By this we also see, that in any step the multiplication of the right-hand matrix and A results in the left-hand matrix.

Note that combining (2) and (3) we can add or subtract a *multiple* of one row from another row. In an integral domain R you may also scratch a common factor a from a row of $(A \mid B)$, as this equals a multiplication by $\frac{1}{a}$ in the quotient field. It would also be possible to use elementary operations of the columns only, but you may not mix both! The algorithm mimics the Gaussian algorithm - let us provide an example of the workings of this method: We compute the inverse of an invertible 4×4 matrix over $\mathbb{Z}$:

$$\begin{array}{rrrr|cccc} 4 & -2 & 5 & 3 & 1 & 0 & 0 & 0 \\ 1 & -1 & 3 & 3 & 0 & 1 & 0 & 0 \\ 0 & -1 & 2 & 1 & 0 & 0 & 1 & 0 \\ -2 & 1 & -2 & 0 & 0 & 0 & 0 & 1 \end{array}$$

First we interchange the first and second row, to move the 1 to the top row. In the next step we eliminate the first column of the left-hand matrix by subtracting 4 times the first row from the second row and adding the double of the first row to the fourth row:

$$\left(\begin{array}{rrrr|rrrr} 1 & -1 & 3 & 3 & 0 & 1 & 0 & 0 \\ 4 & -2 & 5 & 3 & 1 & 0 & 0 & 0 \\ 0 & -1 & 2 & 1 & 0 & 0 & 1 & 0 \\ -2 & 1 & -2 & 0 & 0 & 0 & 0 & 1 \end{array}\right)$$

$$\left(\begin{array}{rrrr|rrrr} 1 & -1 & 3 & 3 & 0 & 1 & 0 & 0 \\ 0 & 2 & -7 & -9 & 1 & -4 & 0 & 0 \\ 0 & -1 & 2 & 1 & 0 & 0 & 1 & 0 \\ 0 & -1 & 4 & 6 & 0 & 2 & 0 & 1 \end{array}\right)$$

We are done with the first row, for now. To iterate we multiply the third row with -1 and interchange the result with the second row. From there we subtract twice the second row from the third row and also add the second row from the fourth row to get one step closer to upper triangular form

$$\left(\begin{array}{rrrr|rrrr} 1 & -1 & 3 & 3 & 0 & 1 & 0 & 0 \\ 0 & 1 & -2 & -1 & 0 & 0 & -1 & 0 \\ 0 & 2 & -7 & -9 & 1 & -4 & 0 & 0 \\ 0 & -1 & 4 & 6 & 0 & 2 & 0 & 1 \end{array}\right)$$

$$\left(\begin{array}{rrrr|rrrr} 1 & -1 & 3 & 3 & 0 & 1 & 0 & 0 \\ 0 & 1 & -2 & -1 & 0 & 0 & -1 & 0 \\ 0 & 0 & -3 & -7 & 1 & -4 & 2 & 0 \\ 0 & 0 & 2 & 5 & 0 & 2 & -1 & 1 \end{array}\right)$$

To eliminate the second-last coefficient in the fourth row we add 2-times the third row to 3-times the forth row. If A wasn't invertible, we might get stuck here, if the last row denies to be continued.

$$\left(\begin{array}{rrrr|rrrr} 1 & -1 & 3 & 3 & 0 & 1 & 0 & 0 \\ 0 & 1 & -2 & -1 & 0 & 0 & -1 & 0 \\ 0 & 0 & -3 & -7 & 1 & -4 & 2 & 0 \\ 0 & 0 & 0 & 1 & 2 & -2 & 1 & 3 \end{array}\right)$$

We're now heading back: Add 7 times row 4 to row 3, add row 4 to row 2 and 3 times row 4 to row 1. This will eliminate the coefficients in the last column up to the lowest one. Doing this, we find

$$\left(\begin{array}{rrrr|rrrr} 1 & -1 & 3 & 0 & -6 & 7 & -3 & -9 \\ 0 & 1 & -2 & 0 & 2 & -2 & 0 & 3 \\ 0 & 0 & -3 & 0 & 15 & -18 & 9 & 21 \\ 0 & 0 & 0 & 1 & 2 & -2 & 1 & 3 \end{array}\right)$$

Here we see, that -3 can be scratched from the third row. From there on, we can add twice row 3 to row 2 and subtract 3-times row 3 from row 1, only leaving the top row. This of course can be handled by adding row 2 to row 1 once more

$$\left(\begin{array}{cccc|cccc} 1 & -1 & 3 & 0 & -6 & 7 & -3 & -9 \\ 0 & 1 & -2 & 0 & 2 & -2 & 0 & 3 \\ 0 & 0 & 1 & 0 & -5 & 6 & -3 & -7 \\ 0 & 0 & 0 & 1 & 2 & -2 & 1 & 3 \end{array}\right)$$

$$\left(\begin{array}{cccc|cccc} 1 & -1 & 0 & 0 & 9 & -11 & 6 & 12 \\ 0 & 1 & 0 & 0 & -8 & 10 & -6 & -11 \\ 0 & 0 & 1 & 0 & -5 & 6 & -3 & -7 \\ 0 & 0 & 0 & 1 & 2 & -2 & 1 & 3 \end{array}\right)$$

$$\left(\begin{array}{cccc|cccc} 1 & 0 & 0 & 0 & 1 & -1 & 0 & 1 \\ 0 & 1 & 0 & 0 & -8 & 10 & -6 & -11 \\ 0 & 0 & 1 & 0 & -5 & 6 & -3 & -7 \\ 0 & 0 & 0 & 1 & 2 & -2 & 1 & 3 \end{array}\right)$$

Altogether we have found the inverse matrix

$$\begin{pmatrix} 4 & -2 & 5 & 3 \\ 1 & -1 & 3 & 3 \\ 0 & -1 & 2 & 1 \\ -2 & 1 & -2 & 0 \end{pmatrix}^{-1} = \begin{pmatrix} 1 & -1 & 0 & 1 \\ -8 & 10 & -6 & -11 \\ -5 & 6 & -3 & -7 \\ 2 & -2 & 1 & 3 \end{pmatrix}$$

4.2 Elementary Matrices

In the previous section we have introduced matrices and the computational operations concerning them - namely the matrix multiplication. We will now study different types of special matrices that can be used to build up all the other matrices by virtue of multiplication. This will be of particular interest for solving linear systems of equations, as all these elementary matrices correspond to a single operation on a system of linear equations.

(4.13) Definition:
Let $(R,+,\cdot)$ be any ring and $1 \leq n \in \mathbb{N}$. Then we will define the set $\mathrm{gl}_n(R)$ of **invertible** matrices, the set $\mathrm{tri}_n(R)$ of **upper triangular** matrices and the set $\mathrm{dia}_n(R)$ of **diagonal** matrices to be the following subsets of $\mathrm{mat}_n(R)$. Likewise a matrix $A \in \mathrm{mat}_n(R)$ is said to be a **lower triangular** matrix, iff $A^* \in \mathrm{tri}_n(R)$ is an upper triangular matrix.

$$\begin{aligned}
\mathrm{gl}_n(R) &:= \{\, A \in \mathrm{mat}_n(R) \mid \exists\, B \in \mathrm{mat}_n(R) \;:\; AB = \mathbb{1}_n = BA \,\} \\
\mathrm{tri}_n(R) &:= \left\{\, A \in \mathrm{mat}_n(R) \mid \forall\, 1 \leq j < i \leq n \;:\; \mathrm{ent}_{i,j}(A) = 0 \right\} \\
\mathrm{tri}^1_n(R) &:= \{\, A \in \mathrm{tri}_n(R) \mid \forall\, 1 \leq i \leq n \;:\; \mathrm{ent}_{i,i}(A) = 1 \,\} \\
\mathrm{dia}_n(R) &:= \left\{ \left(\begin{array}{cccc} a_1 & 0 & \cdots & 0 \\ 0 & a_2 & & 0 \\ \vdots & & \ddots & \\ 0 & 0 & & a_n \end{array} \right) \;\middle|\; a_1, \ldots, a_n \in R \right\}
\end{aligned}$$

(4.14) Proposition: (viz. 1018)
Let $(R,+,\cdot)$ be any ring and $1 \leq n \in \mathbb{N}$. Then the invertible matrices $\mathrm{gl}_n(R)$ are the multiplicative group of the ring mat_R. In particular $\mathrm{gl}_n(R)$ is a (non-commutative) group under the multiplication of matrices

$$\mathrm{gl}_n(R) \;=\; \big(\mathrm{mat}_n(R)\big)^*$$

Also the upper triangular matrices form a sub-ring of the ring $\mathrm{mat}_n(R)$. In particular $\mathrm{tri}_n(R)$ is closed under addition and multiplication of matrices and contains the identity matrix $\mathbb{1}_n$

$$\mathrm{tri}_n(R) \quad \leq_{\mathrm{r}} \quad \mathrm{mat}_n(R)$$

Let now R be a commutative ring and $T = (t_{i,j}) \in \mathrm{tri}_n(R)$ be an upper triangular matrix. Then T is invertible, if and only if for any $i \in 1 \ldots n$ we have $t_{i,i} \in R^*$. And the inverse matrix $T^{-1} \in \mathrm{tri}_n(R)$ is an upper triangular matrix again, such that $\mathrm{tri}_n(R)$ is closed under taking inverses. Also, if T is invertible, we can compute the solution of $Tx = b$ recursively from $i = n$ down to $i = 1$, by

$$\begin{aligned}
x_n &= t_{n,n}^{-1} \\
x_i &= t_{i,i}^{-1} \left(b_i - \sum_{j=i+1}^{n} t_{i,j} x_j \right)
\end{aligned}$$

(4.15) Corollary: (viz. 1019)
If $(R,+,\cdot)$ is a commutative ring and $1 \leq n \in \mathbb{N}$, then any upper triangular matrix $T \in \mathrm{tri}_n^1(R)$ with 1 only on the diagonal is invertible and the inverse T^{-1} is another matrix of this kind. Therefore $\mathrm{tri}_n^1(R)$ is a subgroup of the multiplicative group of $\mathrm{mat}_n(R)$, in formal terms

$$\mathrm{tri}_n^1(R) \quad \leq_{\mathrm{g}} \quad \mathrm{gl}_n(R)$$

Now consider some $A = (a_{i,j})$, $B = (b_{i,j}) \in \mathrm{tri}_n^1(R)$ and suppose that for some $r \in \mathbb{N}$ with $1 \leq r < n$ and any $i \neq j \in 1 \ldots n$ we have both of the implications

(1) If $j \leq r$ then $a_{i,j} = 0$. That is the left r columns of A are 0 apart from the 1 on the diagonal.

(2) If $j > r$ then $b_{i,j} > 0$. That is the right $n - r$ columns of B are 0 apart from the 1 on the diagonal.

$$A = \begin{pmatrix} 1 & & & a_{1,r+1} & \cdots & a_{1,n} \\ & \ddots & & \vdots & & \vdots \\ & & 1 & a_{r,r+1} & & \vdots \\ & & & 1 & \ddots & \vdots \\ & & & & \ddots & a_{n-1,n} \\ & & & & & 1 \end{pmatrix} \quad \text{and} \quad B = \begin{pmatrix} 1 & b_{1,2} & \cdots & b_{1,r} & & \\ & 1 & \ddots & \vdots & & \\ & & \ddots & b_{r-1,r} & & \\ & & & 1 & & \\ & & & & 1 & \\ & & & & & \ddots \\ & & & & & & 1 \end{pmatrix}$$

Then the product matrix AB is just composed of A on the left and B on the right (in the form that is shown below). Beware however, that this need not be true for the reverse BA!

$$AB = \begin{pmatrix} 1 & b_{1,2} & \cdots & b_{1,r} & a_{1,r+1} & \cdots & a_{1,n} \\ & \ddots & \ddots & \vdots & \vdots & & \vdots \\ & & \ddots & b_{r-1,r} & \vdots & & \vdots \\ & & & 1 & a_{r,r+1} & & \vdots \\ & & & & 1 & \ddots & \vdots \\ & & & & & \ddots & a_{n-1,n} \\ & & & & & & 1 \end{pmatrix}$$

(4.16) Definition:
Let $(R,+,\cdot)$ be any ring and $1 \leq n \in \mathbb{N}$. Then we will introduce a number of special $(n \times n)$-matrices. First of all, in analogy to the Euclidean bases, for any $r, s \in 1 \ldots n$ we introduce the **Euclidean matrices**

$$E_{r,s} \quad := \quad (\delta_{i,r}\,\delta_{j,s}) \quad \in \quad \mathrm{mat}_n(R)$$

And if $a_1, \ldots, a_n \in R$ are any scalars we can introduce the **diagonal matrix** having the entries a_i to be

$$\mathrm{dia}(a_1, \ldots, a_n) \quad := \quad \sum_{i=1}^{n} a_i\, E_{i,i} \quad = \quad \begin{pmatrix} a_1 & 0 & \cdots & 0 \\ 0 & a_2 & & 0 \\ \vdots & & \ddots & \\ 0 & 0 & & a_n \end{pmatrix}$$

Another important matrix will simply be denoted by N_n, it is an upper triangular matrix whose only non-zero entries are 1s, one step above (= right of) the diagonal

$$N_n \;:=\; (\delta_{i+1,j}) \;=\; \begin{pmatrix} 0 & 1 & & \\ & 0 & \ddots & \\ & & \ddots & 1 \\ & & & 0 \end{pmatrix} \;\in\; \mathrm{tri}_n(R)$$

Now, if $a \in R$ and $i, j \in 1 \ldots n$, we define a **dilatation matrix** $D_i(a)$ and a **translocation matrix** $T_{i,j}(a)$ to be $(n \times n)$-matrices of the following form

$$\begin{aligned} T_{i,j}(a) &:= \mathbb{1}_n + aE_{i,j} \\ D_i(a) &:= \mathbb{1}_n + (a-1)E_{i,i} \end{aligned}$$

Consider any $i, j \in 1 \ldots n$ again, then we define a **transposition matrix** $P_{i,j}$ to to be an $(n \times n)$-matrices of the following form

$$P_{i,j} \;=\; \mathbb{1}_n - E_{i,i} - E_{k,k} + E_{i,k} + E_{k,i}$$

More generally, let us denote the Euclidean basis of R^n by $e_j = (\delta_{i,j})$ again. That is $e_1 = (1,0,0,\ldots,0)$, $e_2 = (0,1,0,\ldots,0)$ and so on until $e_n = (0,\ldots,0,0,1)$. Then for any function $\sigma : 1 \ldots n \to 1 \ldots n$ we define **permutation matrix** P_σ of σ to be the following

$$P_\sigma \;:=\; (\delta_{\sigma(i),j}) \;=\; \begin{pmatrix} \text{—} & e_{\sigma(1)} & \text{—} \\ & \vdots & \\ \text{—} & e_{\sigma(n)} & \text{—} \end{pmatrix} \;\in\; \mathrm{mat}_n(R)$$

We denote the set of all transposition matrices $P_{i,j}$ and all translocation matrices $T_{i,j}(a)$ (where $i, j \in 1 \ldots n$ with $i \neq j$ and $a \in R$) of size n over R by

$$\mathrm{Elm}_n^1(R) \;:=\; \{\, P_{i,j} \mid i,j \in 1 \ldots n \,\} \cup \{\, T_{i,j}(a) \mid i \neq j \in 1 \ldots n,\, a \in R \,\}$$

The set of **elementary matrices** finally consists of all dilatation matrices $D_i(a)$ (where $i \in 1 \ldots n$), all translocation matrices $T_{i,j}(a)$ and all transposition matrices $P_{i,j}$ (where $i \neq j$ again). We denote it by

$$\mathrm{Elm}_n(R) \;:=\; \mathrm{Elm}_n^1(R) \cup \{\, D_i(a) \mid i \in 1 \ldots n,\, a \in R \,\}$$

If finally A and $B \in \mathrm{mat}_{m,n}(R)$ are matrices of the same size over R, then we say that A and B are **elementary equivalent** iff there are elementary matrices $E_1, E_2, \ldots, E_r \in \mathrm{Elm}_m^1(R)$ and $F_1, F_2, \ldots, F_s \in \mathrm{Elm}_n^1(R)$ such that $B = E_1E_2 \ldots E_rAF_1F_2 \ldots F_s$. We denote this by

$$A \equiv B \;:\Longleftrightarrow\; \begin{array}{l} \exists\, E_i \in \mathrm{Elm}_m^1(R) \text{ and } \exists\, F_h \in \mathrm{Elm}_m^1(R) \\ \text{such that } \; B = E_1E_2 \ldots E_rAF_1F_2 \ldots F_s \end{array}$$

(4.17) Remark:
The above definitions are formally correct but some of them are a little bit obfuscated. Hence we wish to enlighten them by rewriting the respective formulas in matrix notation:

- First of all - for $i \neq j$ - the translocation matrix $T_{i,j}(a)$ is just the identity matrix $\mathbb{1}_n$ with the (i,j)-th entry being a instead of 0. Intuitively speaking that is

$$T_{i,j}(a) \;=\; \begin{pmatrix} 1 & & & & & & \\ & \ddots & & & & & \\ & & 1 & & a & & \\ & & & \ddots & & & \\ & & & & 1 & & \\ & & & & & \ddots & \\ & & & & & & 1 \end{pmatrix}$$

- By definition the transposition matrix $P_{i,j}$ is the identity matrix in which the (i,i)-th entry 1 is moved to (j,i) and the (j,j)-the entry 1 is moved to (i,j). In that we find that $P_{i,j}$ is the permutation matrix that belongs to $(i\ j)$, i.e. the permutation that interchanges i and j

$$P_{i,j} \;=\; P_{(i\ j)} \;=\; \begin{pmatrix} 1 & & & & & & \\ & \ddots & & & & & \\ & & 0 & & 1 & & \\ & & & \ddots & & & \\ & & 1 & & 0 & & \\ & & & & & \ddots & \\ & & & & & & 1 \end{pmatrix}$$

- It is quite obvious that all the matrices of $\mathrm{Elm}_n^1(R)$ are invertible - in fact we will see in (4.21) that $P_{i,j}^{-1} = P_{i,j}$ and $T_{i,j}(a)^{-1} = T_{i,j}(-a)$. Therefore elementary equivalence $\equiv$ is an equivalence relation on the set $\mathrm{mat}_{m,n}(R)$ of matrices of a given size $(m \times n)$.

- Lastly all the dilatation matrices $D_i(a)$ are nothing but a diagonal matrix - start with the identity matrix $\mathbb{1}_n$ but replace the (i,i)-th coefficient by a. That is

$$D_i(a) \;=\; \mathrm{dia}(\ \underbrace{1,\ldots,a,\ldots,1}_{a \text{ at } i\text{-th position}}\) \;=\; \begin{pmatrix} 1 & & & & \\ & \ddots & & & \\ & & a & & \\ & & & \ddots & \\ & & & & 1 \end{pmatrix}$$

(4.18) Proposition: (viz. 1020)
Let $(R, +, \cdot)$ be any ring and $1 \leq m, n \in \mathbb{N}$. Then we obtain the following formulae when multiplying one of the above matrices with another matrix

(i) For any $r, s \in 1\ldots$ let $E_{r,s} \in \mathrm{mat}_n(R)$ denote the respective Euclidean matrix. Then for any $(m \times n)$-matrix $A \in \mathrm{mat}_{m,n}(R)$ and any $(n \times m)$-matrix $B \in \mathrm{mat}_{n,m}(R)$ we get

$$\begin{aligned} \mathrm{col}_k(AE_{r,s}) &= \begin{cases} \mathrm{col}_r(A) \text{ if } k = s \\ 0 \text{ if } k \neq s \end{cases} \\ \mathrm{row}_i(E_{r,s}B) &= \begin{cases} \mathrm{row}_s(B) \text{ if } i = r \\ 0 \text{ if } i \neq r \end{cases} \end{aligned}$$

(ii) Consider the square matrix $A = (a_{i,j}) \in \mathrm{mat}_n(R)$, then for any four indexes i, j, k and $l \in 1\ldots n$ we have the following identity

$$E_{i,j}\, A\, E_{k,l} = a_{j,k}\, E_{i,l}$$

In particular, if we apply this equation to the identity matrix $A = \mathbb{1}_n = (\delta_{i,j})$, we also get

$$E_{i,j}\, E_{k,l} = \delta_{j,k}\, E_{i,l}$$

(iii) For any $r, s \in 1\ldots$ let $E_{r,s} \in \mathrm{mat}_n(R)$ denote the respective Euclidean matrix again. Also let $a \in R$, $A \in \mathrm{mat}_{m,n}(R)$ and $B \in \mathrm{mat}_{n,m}(R)$. Multiplying with the translocation matrix $T_{r,s}(a)$ from the left adds a-times the s-th row to the r-th row of B. Likewise, multiplying with $T_{r,s}(a)$ from the right adds a-times the r-th column to the s-th column of A. That is for any $i, j \in 1\ldots n$ we get

$$\begin{aligned} \mathrm{col}_k(AT_{r,s}(a)) &= \begin{cases} \mathrm{col}_k(A) + \mathrm{col}_r(A)\, a \text{ if } k = s \\ \mathrm{col}_k(A) \text{ if } k \neq s \end{cases} \\ \mathrm{row}_i(T_{r,s}(a)B) &= \begin{cases} \mathrm{row}_i(B) + a\, \mathrm{row}_s(B) \text{ if } i = r \\ \mathrm{row}_i(B) \text{ if } i \neq r \end{cases} \end{aligned}$$

(iv) Consider any $a_1, \ldots, a_n \in R$ and any $x_1, \ldots, x_n \in R^m$, then the multiplication the diagonal matrix of the a_j is nothing but the scalar multiplication with these elements, formally

$$\mathrm{dia}(a_1, \ldots, a_n) \begin{pmatrix} — & x_1 & — \\ & \vdots & \\ — & x_n & — \end{pmatrix} = \begin{pmatrix} — & a_1x_1 & — \\ & \vdots & \\ — & a_nx_n & — \end{pmatrix}$$

$$\begin{pmatrix} | & & | \\ x_1 & \cdots & x_n \\ | & & | \end{pmatrix} \mathrm{dia}(a_1, \ldots, a_n) = \begin{pmatrix} | & & | \\ x_1a_1 & \cdots & x_na_n \\ | & & | \end{pmatrix}$$

(v) Multiplying N_n from the right shifts the rows up one step, multiplying with N_n from the left shifts the columns right one step. Formally put: Consider any $x_1, \ldots, x_n \in R^m$ then we get

$$N_n \begin{pmatrix} \text{---} & x_1 & \text{---} \\ \text{---} & x_2 & \text{---} \\ & \vdots & \\ \text{---} & x_n & \text{---} \end{pmatrix} = \begin{pmatrix} \text{---} & x_2 & \text{---} \\ & \vdots & \\ \text{---} & x_n & \text{---} \\ \text{---} & 0 & \text{---} \end{pmatrix}$$

$$\begin{pmatrix} | & | & & | \\ x_1 & x_2 & \cdots & x_n \\ | & | & & | \end{pmatrix} N_n = \begin{pmatrix} | & | & & | \\ 0 & x_1 & \cdots & x_{n-1} \\ | & | & & | \end{pmatrix}$$

(vi) If $x_1, \ldots, x_n \in R^m$ again and $\sigma : 1 \ldots n \to 1 \ldots n$ is an arbitrary function, then multiplying with the permutation matrix P_σ from the left permutes the rows with σ, formally

$$P_\sigma \begin{pmatrix} \text{---} & x_1 & \text{---} \\ & \vdots & \\ \text{---} & x_n & \text{---} \end{pmatrix} = \begin{pmatrix} \text{---} & x_{\sigma(1)} & \text{---} \\ & \vdots & \\ \text{---} & x_{\sigma(n)} & \text{---} \end{pmatrix}$$

Now suppose, that $\sigma : 1 \ldots n \to 1 \ldots n$ even is bijective. Then multiplying with the permutation matrix P_σ from the right permutes the columns with σ^{-1}, formally

$$\begin{pmatrix} | & & | \\ x_1 & \cdots & x_n \\ | & & | \end{pmatrix} P_\sigma = \begin{pmatrix} | & & | \\ x_{\sigma^{-1}(1)} & \cdots & x_{\sigma^{-1}(m)} \\ | & & | \end{pmatrix}$$

(4.19) Remark:
In the next section we will introduce the Gaussian algorithm that builds up a matrix $S \in \mathrm{mat}_m(R)$ such that SA is in echelon-form (something like an upper triangular matrix). Let r_i be the i-th row of A

$$A = \begin{pmatrix} \text{---} & r_1 & \text{---} \\ & \vdots & \\ \text{---} & r_m & \text{---} \end{pmatrix} \in \mathrm{mat}_{m,n}(R)$$

As thereby S will be a product $S = E_1 E_2 \ldots E_\ell$ of elementary matrices $E_k \in \mathrm{Elm}_m(R)$ this means that SA is formed out of $A \in \mathrm{mat}_{m,n}(R)$ *by operations on the rows* of A, as we have just seen:

$P_{i,j}\, A$	interchanges r_i and r_j
$T_{i,j}(a)\, A$	adds a-times r_j to r_i
$D_i(a)\, A$	multiplies r_i by a

(4.20) Proposition: (viz. 1018)
Let $(R,+,\cdot)$ be a commutative ring, $1 \leq p, m, n \in \mathbb{N}$ and consider a set of vectors $\{ x_1, x_2, \ldots, x_m \} \subseteq R^p$. Now suppose $\{ y_1, y_2, \ldots, y_n \} \subseteq R^p$ is another set of vectors, that are linear combinations of the x_j

$$y_k \;=\; \sum_{j=1}^{m} a_{j,k} x_j \;\in\; R^p$$

for any $k \in 1 \ldots n$ and some coefficients $a_{j,k} \in R$. Then, if we denote the matrix of these coefficients by $A = (a_{j,k}) \in \mathrm{mat}_{m,n}(R)$, then we find the identity

$$\begin{pmatrix} | & & | \\ y_1 & \cdots & y_n \\ | & & | \end{pmatrix} \;=\; \begin{pmatrix} | & & | \\ x_1 & \cdots & x_m \\ | & & | \end{pmatrix} A$$

(4.21) Corollary: (viz. 1023)
Let $(R,+,\cdot)$ be any ring and $1 \leq n \in \mathbb{N}$, then we summarize our results concerning the inverse matrices of the various elementary matrices

(i) The set of diagonal matrices is a R-subalgebra of $\mathrm{mat}_n(R)$, that is isomorphic to the R-algebra R^n. The isomorphism thereby is given by

$$R^n \;\xrightarrow{\sim}\; \mathrm{dia}_n(R) \;:\; (a_1, \ldots, a_n) \mapsto \mathrm{dia}(a_1, \ldots, a_n)$$

In particular the matrix $\mathrm{dia}(a_1, \ldots, a_n)$ is invertible if and only if all the a_i are invertible in R, i.e. $a_i \in R^*$. And in this case the inverse matrix is given to be

$$\mathrm{dia}(a_1, \ldots, a_n)^{-1} \;=\; \mathrm{dia}(a_1^{-1}, \ldots, a_n^{-1})$$

(ii) In particular the dilatation matrix $D_i(ab)$ is the product of $D_i(a)$ and $D_i(b)$. Therefore $D_i(a)$ is invertible if and only if $a \in R^*$ is a unit in R and in this case the inverse is $D_i(a^{-1})$. Altogether for any $i \in 1 \ldots n$ and any $a, b \in R$ we have the identities

$$\begin{aligned} D_i(a)\, D_i(b) &= D_i(ab) \\ D_i(a)^{-1} &= D_i\left(a^{-1}\right) \end{aligned}$$

(iii) For any $i \neq j \in 1 \ldots n$ the product of the transposition matrices $T_{i,j}(a)$ and $T_{i,j}(b)$ is the transposition matrix $T_{i,j}(a+b)$. In particular any transposition matrix is invertible, the inverse of $T_{i,j}(a)$ For any $i \neq j \in 1 \ldots n$ being $T_{i,j}(-a)$. Altogether for any $i \neq j$ and any $a, b \in R$ we have

$$\begin{aligned} T_{i,j}(a)\, T_{i,j}(b) &= T_{i,j}(a+b) \\ T_{i,j}(a)^{-1} &= T_{i,j}(-a) \end{aligned}$$

(iv) Let us denote the identity map by $id : 1 \dots n \to 1 \dots n : i \mapsto i$. Then clearly the permutation matrix of id is the identity matrix $P_{id} = \mathbb{1}_n$. And if σ and $\tau : 1 \dots n \to 1 \dots n$ are any two functions (not necessarily permutations) on $1 \dots n$, then the product $P_\sigma P_\sigma$ of the permutation matrices is the permutation matrix of $\tau\sigma$ (i.e. in reverse order!), formally

$$P_\sigma P_\tau \;=\; P_{\tau\sigma}$$

In particular the permutation matrix P_σ of σ is invertible, if and only if σ is bijective, and in this case the inverse is the permutation matrix of σ^{-1} which is the transpose of P_σ, altogether

$$P_\sigma^{-1} \;=\; P_{\sigma^{-1}} \;=\; P_\sigma^*$$

(v) If $A = (a_{i,j}) \in \mathrm{mat}_{m,n}(R)$ is any matrix of any size and $\varrho \in S_m$ and $\sigma \in S_n$ are permutations of $1 \dots m$ and $1 \dots n$ respectively, then $P_\varrho A P_\sigma^{-1} \in \mathrm{mat}_{m,n}(R)$ is given to be the matrix

$$P_\varrho \, A \, P_\sigma^{-1} \;= \left(a_{\varrho(i),\sigma(j)}\right) \;= \begin{pmatrix} a_{\varrho(1),\sigma(1)} & \cdots & a_{\varrho(1),\sigma(n)} \\ \vdots & & \vdots \\ a_{\varrho(m),\sigma(1)} & \cdots & a_{\varrho(m),\sigma(n)} \end{pmatrix}$$

4.3 Linear Equations

A **system of equations** is a (finite) collection of equations for several variables $x_1, \dots, x_n$ over some ring R. That is we are given some functions $f_i : R^n \to R$ and some $b_i \in R$ (where $i \in 1 \dots m$) and consider

$$\begin{aligned} f_1(x_1, \dots, x_n) &= b_1 \\ f_2(x_1, \dots, x_n) &= b_2 \\ \vdots \quad \vdots &\quad \vdots \\ f_m(x_1, \dots, x_n) &= b_m \end{aligned}$$

A **solution** of this system of equations is an n-tuple $(x_1, \dots, x_n) \in R^n$ that satisfies all the equations above. The set of solutions is sometimes denoted by

$$\mathbb{L} \;=\; \{\, x \in R^n \mid \forall\, i \in 1 \dots m : f_i(x) = b_i \,\}$$

However the question remains how to solve such a system of equations. In this generality the problem is absolutely unsolvable. In fact very little can be said for sure: In the case $R = \mathbb{R}$ or $R = \mathbb{C}$ there is the *local inversion theorem* which (under certain conditions) guarantees the existence of a solution. The set of solutions is then called a *manifold* and the branch of *differential geometry* studies these. And if all the f_i are polynomial and R is an algebraically closed field, then *algebraic geometry* studies the structure of the set of solutions. To truly find a solution is a different story, however.

The one and only case in which a complete theory of solving a system of equations exists is the case of linear equations. Thereby the system is said to be **linear**, iff all the f_i are multi-linear, i.e. iff any $x_k \mapsto f_i(\dots, x_k, \dots)$ is R-linear. In this case the system of equations is of the form

$$\begin{array}{ccccccccc} a_{1,1}x_1 & + & a_{1,2}x_2 & + & \dots & + & a_{1,n}x_n & = & b_1 \\ a_{2,1}x_1 & + & a_{2,2}x_2 & + & \dots & + & a_{2,n}x_n & = & b_2 \\ \vdots & & & & & & \vdots & = & \vdots \\ a_{m,1}x_1 & + & a_{m,2}x_2 & + & \dots & + & a_{m,n}x_n & = & b_m \end{array}$$

for some fixed *coefficients* $a_{i,k} \in R$ and $b_i \in R$ (where $i \in 1 \dots m$ and $k \in 1 \dots n$). Note that matrices provide a very compact notation for linear systems of equations. Just let $A = (a_{i,k}) \in \mathrm{mat}_n(R)$ be the matrix of the coefficients and $b = (b_1, \dots, b_m) \in R^m$, then the above system boils down to a single equation for vectors (that is finite tuples over R)

$$Ax \;=\; b$$

Still a notation does not provide an algorithm of solving the equations. Now this is the purpose of this section and we start by giving an example:

$$\begin{aligned} (1) \quad 2x_1 + 2x_2 - 3x_3 + 2x_4 &= 8 \\ (2) \quad 2x_1 + 4x_2 + 8x_3 - 4x_4 &= 6 \\ (3) \quad -3x_1 - 4x_2 + x_4 &= 1 \end{aligned}$$

This is a (3×4)-system and we seek all 4-tuples (x_1, x_2, x_3, x_4) satisfying all 3 equations above. The problem is that these equations are interlocked with each other, so let us try to disentangle these equations. We see that subtracting equation (1) from equation (2) the coefficient of x_1 vanishes, so let's try $(2) - (1) \to (2)$. With equation (3) the case is not so simple, but it works out fine with $3(1) + 2(3) \to (3)$

$$\begin{array}{lrcl} (1) & 2x_1 + 2x_2 - 3x_3 + 2x_4 & = & 8 \\ (2) & 2x_2 + 11x_3 - 6x_4 & = & -2 \\ (3) & -2x_2 - 9x_3 + 8x_4 & = & 26 \end{array}$$

So we have reduced the problem by the variable x_1 at the cost of equation (1) - if we continue using (1), then x_1 will reappear. So we restrict ourselves to (2) and (3). To eliminate x_2 let us add (2) and (3) and make the result or equation (3), i.e. $(2) + (3) \to (3)$

$$\begin{array}{lrcl} (1) & 2x_1 + 2x_2 - 3x_3 + 2x_4 & = & 8 \\ (2) & 2x_2 + 11x_3 - 6x_4 & = & -2 \\ (3) & 2x_3 + 2x_4 & = & 24 \end{array}$$

Let us suppose $R = \mathbb{Q}$, then dividing by 2 we found $x_3 + x_4 = 12$ - this is a multitude of solutions, every x_4 gives rise to another x_3 since equation (3) is just $x_3 = 12 - x_4$. But by equation (2) this now means $2x_2 = -2 - 11(12 - x_4) + 6x_4 = -134 + 17x_4$ and hence $x_2 = -67 + 17x_4/2$. This can be inserted into equation (1) $2x_1 = 8 - (-134 + 17x_4) + 3(12 - x_4) + 2x_4 = 178 - 22x_4$ and hence $x_1 = 89 - 11x_4$. Altogether any solution x of this system of equations is of the form

$$\begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} \in \begin{pmatrix} 89 \\ -67 \\ 12 \\ 0 \end{pmatrix} + \mathbb{Q} \begin{pmatrix} -11 \\ 17/2 \\ -1 \\ 1 \end{pmatrix}$$

(4.22) Example:
Before we proceed to develop a complete theory for solving systems of linear equations (SLE) let us regard some standard examples of vector-geometry. The idea how to solve an SLE always is to add multiples of one equation to another with the aim of finding a new equation in which one variable has been eliminated. In consequence, if there are less equations than variables, there will remain some free variables. These constitute a space of solutions.

- Let us regard the equation $2x_1 + x_2 = 1$ where the variables run over $x = (x_1, x_2) \in \mathbb{R}^2$. This is equivalent, to $x_2 = -2x_1 + 1$ such that we can already write down the general solution of this equation

 $$x = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} x_1 \\ 1 - 2x_1 \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \end{pmatrix} + x_1 \begin{pmatrix} 1 \\ -2 \end{pmatrix}$$

 Geometrically speaking, the set of solutions forms a line in the plane $\mathbb{R}^2$ that runs through $(0, 1)$ in the direction of $(1, -2)$ - refer to section 4.8 for details.

- If we regard the equation $2x_1 + x_2 = 1$ with variables $x = (x_1, x_2, x_3) \in \mathbb{R}^3$ then x_3 clearly is missing. Nevertheless we may rewrite it in the form $x_2 = 1 - 2x_1$. So if we now look at the set of solutions, we find

$$x = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = \begin{pmatrix} x_1 \\ 1 - 2x_1 \\ x_3 \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} + x_1 \begin{pmatrix} 1 \\ -2 \\ 0 \end{pmatrix} + x_3 \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}$$

 Geometrically speaking, the set of solutions now forms a plane in three dimensional $\mathbb{R}^3$ space that runs through $(0,1,0)$ in the directions of $(1,-2,0)$ and $(0,0,1)$ - this will be covered in 4.8, too.

- The equation $2x_1 - x_2 + 3x_3 = 2$ describes a plane in three dimensional space, that lies perpendicular to $(2,-1,3)$. It is easy to see, that e.g. $(1,0,0)$ is a point contained in that plane. Given another plane, described by $-4 + 4x_2 - 5x_3 = 4$ it stands to reason that the intersection of these two planes should be a line. This line consists of all those $x = (x_1, x_2, x_3) \in \mathbb{R}^3$, that solve both equations *simultaneously*. That is it consists precisely of the solutions of the SLE

$$\begin{array}{rrcl} (1) & 2x_1 - x_2 + 3x_3 & = & 2 \\ (2) & -4x_1 + 4x_2 - 5x_3 & = & 4 \end{array}$$

 It is clear, that we can eliminate x_1 form the second equation, by adding the double of equation (1), that is we replace $2(1) + (2) \to (2)$ and end up, with

$$\begin{array}{rrcl} (1) & 2x_1 - x_2 + 3x_3 & = & 2 \\ (2) & 2x_2 + x_3 & = & 8 \end{array}$$

 This new equation (2) can now be reformulated as $x_3 = 8 - 2x_2$ and if we insert this information into equation (1) we get $2x_1 = 2 + x_2 - 3x_3 = 2 + x_2 - 3(8 - 2x_2) = -22 + 7x_2$. By dividing with 2 (in case of the base ring $R = \mathbb{R}$ this is not a problem) we find $x_1 = -11 + 3.5x_2$. Hence the intersection of the planes is given to be

$$x = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = \begin{pmatrix} -11 + 3.5x_2 \\ x_2 \\ 8 - 2x_2 \end{pmatrix} = \begin{pmatrix} -11 \\ 0 \\ 8 \end{pmatrix} + x_2 \begin{pmatrix} 3.5 \\ 1 \\ -2 \end{pmatrix}$$

 Geometrically speaking, the set of solutions forms a line in three dimensional space that runs through $(-11,0,8)$ in the direction of $(3.5,1,-2)$. Of course a line was expected, as we started with intersecting two planes.

- Let us now regard two lines in three dimensional space: g runs through $(7,8,0)$ in the direction of $(2,2,-1)$ and h through $(-3,0,9)$ in the direction of $(2,1,3)$

$$g(s) = \begin{pmatrix} 7 \\ 8 \\ 0 \end{pmatrix} + s \begin{pmatrix} 2 \\ 2 \\ -1 \end{pmatrix} \quad h(t) = \begin{pmatrix} -3 \\ 0 \\ 9 \end{pmatrix} + t \begin{pmatrix} 2 \\ 1 \\ -3 \end{pmatrix}$$

We now want to know, whether these lines intersect and (in case they do) at which point that is. To answer this we regard the equation

$$\begin{pmatrix} 7 \\ 8 \\ 0 \end{pmatrix} + s \begin{pmatrix} 2 \\ 2 \\ -1 \end{pmatrix} = \begin{pmatrix} -3 \\ 0 \\ 9 \end{pmatrix} + t \begin{pmatrix} 2 \\ 1 \\ -3 \end{pmatrix}$$

Written explicitly this is a SLE having 3 equations and 2 the variables s and t. We already present this SLE in standard form:

$$\begin{array}{lrcl} (1) & 2s - 2t & = & -10 \\ (2) & 2s - t & = & -8 \\ (3) & -s + 3t & = & 9 \end{array}$$

We now divide equation (1) by to and add the result to (3), that is $(1)/2 \to (1)$ and $(1) + (3) \to (3)$. We hence get

$$\begin{array}{lrcl} (1) & s - t & = & -5 \\ (2) & 2s - t & = & -8 \\ (3) & 2t & = & 4 \end{array}$$

Dividing equation (3) by 2 as well, we find $t = 2$. And if the insert this result into equation (1) we also find $s = -5 + t = -3$. Note that we have not used equation (2) so far, but it also imposes a condition on (s,t). Let us check the result in equation (2): $2s - t = 2 \cdot (-3) - 2 = -8$ is satisfied. That means, $(s,t) = (-3,2)$ truly is a solution of the SLE and in fact we find the common point on the lines g and h:

$$g(-3) \;=\; h(2) \;=\; \begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix}$$

(4.23) Proposition: (viz. 845)
Let $(R,+,\cdot)$ be an arbitrary ring, $1 \leq m$, $n \in \mathbb{N}$ and consider any matrix $A \in \mathrm{mat}_{m,n}(R)$ over R. Finally let $x \in R^n$ and $b \in R^m$, then we obtain the following statements

(i) Let us denote $\mathbb{L}(Ax = b) := \{\, x \in R^n \mid Ax = b \,\}$ the set of solutions of the linear system $Ax = b$ of equations. If $b \notin \mathrm{im}(A)$ then there is no solution $\mathbb{L}(Ax = b) = \emptyset$. Conversely if $b \in \mathrm{im}(A)$ then there is some *special solution* $u \in R^n$ with $Au = b$. And for any such u the set of solutions is then given to be

$$\mathbb{L}(Ax = b) \;=\; u + \mathrm{kn}(A)$$

(ii) If $S \in \mathrm{gl}_n(R)$ and $T \in \mathrm{gl}_m(R)$ are any two invertible matrices, let us denote $D := SAT \in \mathrm{mat}_{m,n}(R)$. Thereby the following two statements are equivalent

(a) $Ax \;=\; b$

(b) there is some $z \in R^n$ such that $x = Tz$ and $Dz = Sb$

(iii) If we use notation of (i) and (ii) before, then the set of solutions of $Ax = b$ can be reformulated as

$$\mathbb{L}(Ax = b) \;=\; T\,\mathbb{L}(Dx = Sb)$$

(iv) Let us continue with (iii), if $Sb \notin \mathrm{im}(D)$ then there is no solution $\mathbb{L}(Ax = b) = \emptyset$. Conversely if $Sb \in \mathrm{im}(D)$ then there is some $u \in R^n$ with $Du = Sb$. And the set of solutions is then given to be

$$\mathbb{L}(Ax = b) \;=\; Tu + T\,\mathrm{kn}(D)$$

(4.24) Example: (viz. 845) **Diophantine Equation:**
Consider some Euclidean domain (R, ν) such as $R = \mathbb{Z}$ and pick up some coefficients $a_1, \ldots, a_n \in R$ where we assume the $a_i \neq 0$ to be non-zero. Then we consider the linear equation

$$L(x) \;:=\; a_1x_1 + \cdots + a_nx_n \;=\; b$$

where $b \in R$ again. Thereby the set of solutions is $\mathbb{L} = \{\, x \in R^n \mid L(x) = b \,\}$. In order to present a complete set of solutions for this equation let us proceed one step at a time:

- Let us denote a greatest common divisor of the coefficients by $d \in \gcd\{\, a_1, \ldots, a_n \,\}$. Then the equation $L(x) = b$ admits a solution $x \in R^n$ if and only if d divides b. Formally that is

 $$\mathbb{L} \neq \emptyset \quad\Longleftrightarrow\quad d \mid b$$

 This is due to proposition (2.83.(iii)) which tells us, that $\mathrm{im}(L) = dR$. In fact the enhanced Euclidean algorithm (2.72) provides some $u_1, \ldots, u_n \in R$ such that $a_1u_1 + \cdots + a_nu_n = d$. And thereby we get a special solution $s \in R^n$ of $L(x) = b$ by taking

 $$s \;=\; \left(\frac{b}{d}u_1,\; \ldots,\; \frac{b}{d}u_n\right) \;\in\; \mathbb{L}$$

- In case $n = 1$ the solution is quite simple and uniquely determined: Since $d = a_1$ we have a solution to $a_1x_1 = b$ if and only if $a_1 \mid b$. In this case the solution $x_1 = b/a_1$ is uniquely determined and can be computed by division with remainder.

- In case $n \geq 2$ it is clear that the solution cannot be uniquely determined any longer, as L will have a non-zero kernel. In fact we know by (4.23) that $\mathbb{L} = s + \mathrm{kn}(L)$, where s is any solution $L(s) = b$, e.g. the one presented above, using the enhanced Euclidean algorithm. In the next step we will look at the kernel in case $n = 2$ only: Here we find that $\mathrm{kn}(L) = (a_2/d, -a_1/d)R$ such that altogether the set of solutions is given to be

 $$\mathbb{L} \;=\; \left(\frac{b}{d}u_1,\; \frac{b}{d}u_2\right) + \left\{\, \left(\frac{a_2}{d}t,\; -\frac{a_1}{d}t\right) \mid t \in R \,\right\}$$

- In case $n \geq 3$ let us denote some greatest common divisor of the first $k \in 2 \ldots n$ coefficients by $d_k \in \gcd\{\, a_1, \ldots, a_k \,\}$. In the notation above that is $d_n = d$. Also pick up some $u_{i,k} \in R$ (where

$1 \leq i \leq k$, e.g. using the enhanced Euclidean algorithm) such that we get

$$a_1 u_{1,k} + \cdots + a_k u_{k,k} \;=\; d_k$$

We already know $\mathbb{L} = s + \mathrm{kn}(L)$, but we now give an explicit description of the kernel $\mathrm{kn}(L)$ to be the image of the following $n \times (n-1)$ matrix A. That is we have $\mathrm{kn}(L) = \mathrm{im}(A)$ and hence $\mathbb{L} = s + \mathrm{im}(A)$, where

$$A \;=\; \begin{pmatrix} a_2/d_2 & a_3 u_{1,2}/d_3 & \cdots & a_n u_{1,n-1}/d_n \\ -a_1/d_2 & a_3 u_{2,2}/d_3 & \cdots & a_n u_{2,n-1}/d_n \\ 0 & -d_2/d_3 & & a_n u_{3,n-1}/d_n \\ \vdots & 0 & \ddots & \vdots \\ \vdots & \vdots & & a_n u_{n-1,n-1}/d_n \\ 0 & 0 & & -d_{n-1}/d_n \end{pmatrix}$$

Formally that is $A = (a_{i,k}) \in \mathrm{mat}_{n,n-1}(R)$ is the matrix given by the coefficients $(a_{1,1}, \ldots, a_{n,1}) = (a_2/d_2, -a_1/d_2, 0, \ldots, 0)$ and for any $i \in 2 \ldots n$ and $k \in 1 \ldots n-1$ we have

$$a_{i,k} \;:=\; \begin{cases} a_{k+1} u_{i,k}/d_{k+1} \text{ if } i < k \\ -d_k/d_{k+1} \text{ if } i = k \\ 0 \text{ if } i > k \end{cases}$$

Proposition (4.23) provides a strategy for solving linear systems $Ax = b$ of equations: Find invertible matrices S and T such that $D = SAT$ becomes an *easy* matrix. Well, D is *easy* if the equation $Dx = Sb$ can be solved easily. This of course is the case, if D is something like a diagonal matrix - one entry per column - as in this case we do not have an interlocked *system* of equations, but simply n separate equations of the form $a_i x_i = b_i$.
So we will have to define, when the matrix D is *easy* (this will be called the *Gauss-form*) and we have to provide a way of finding S and T - this will be the *Gauss-algorithm*. Then we only have to solve $Du = Sb$ (supposed such an u exists), as then $\mathbb{L}(Ax = b) = Tu + T\,\mathrm{kn}(D)$.

(4.25) Definition:
Let $(R, +, \cdot)$ be an arbitrary ring and $1 \leq m, n \in \mathbb{N}$, then for any n-tuple $a = (a_1, \ldots, a_n) \in R^n$ with $a \neq 0$ we denote the index of the first non-zero entry of a by $\mu(a)$, that is

$$\mu(a) \;:=\; \min\{\, k \in 1 \ldots n \mid a_k \neq 0 \,\} \;\in\; 1 \ldots n$$

Specifically for $a = 0$ we let $\mu(a) := \infty$. Analogously for an $(m \times n)$-matrix $A \in \mathrm{mat}_{m,n}(R)$ with $A = (a_{i,k})$ we let $\mu(0) := \infty$ and for $A \neq 0$ we define $\mu(A)$ to be the index of the first non-zero entry of any of its rows, formally again

$$\begin{aligned} \mu(A) \;&:=\; \min\{\, \mu(\mathrm{row}_i A) \mid i \in 1 \ldots m : a_k \neq 0 \,\} \\ &=\; \min\{\, k \in 1 \ldots n \mid \exists\, i \in 1 \ldots m : a_{i,k} \neq 0 \,\} \end{aligned}$$

(4.26) Definition:
Let $(R,+,\cdot)$ be an arbitrary ring and $1 \leq m,n \in \mathbb{N}$ again, then a matrix $A \in \mathrm{mat}_{m,n}(R)$ is said to be in **echelon-form**, iff either $A = 0$ is zero, or $A \neq 0$ and there is some $r \in 1 \ldots m$ such that:

(1) $\mu(\mathrm{row}_1 A) < \cdots < \mu(\mathrm{row}_r A)$ and

(2) $\forall\, i \in \mathbb{N}$ with $r < i \leq m$ we have $\mathrm{row}_i(A) = 0$

That is the non-zero entries of A form a descending (from top left to bottom right) stair. In particular the zero-rows of A are at the bottom of A. Now A is said to be in **Gauss-form**, iff A is in echelon-form and any non-zero row begins with a $1 \in R$ (not just any non-zero element of R). That is: let $r \in \mathbb{N}$ be as before, $r := \max\{\, i \in 1 \ldots m \mid \mathrm{row}_i A \neq 0 \,\}$ and let us abbreviate $k(i) := \mu(\mathrm{row}_i A)$ for any $i \in 1 \ldots r$, then A is in Gauss-form, iff also

(3) $\forall\, i \in 1 \ldots r$ we get $a_{i,k(i)} = 1$

(4.27) Example:
The following (3×4)-matrix features $r = 2$, $\mu(\mathrm{row}_1 A) = 1$, $\mu(\mathrm{row}_2 A) = 3$ and $\mu(\mathrm{row}_3 A) = \infty$ and hence is in echelon-form. However it is not in Gauss-form, as $\mathrm{ent}_{2,3} A = 2 \neq 1$

$$A \;=\; \begin{pmatrix} 1 & 0 & -1 & 4 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

The next example of a (4×4)-matrix is *not* in echelon-form, as the second column features a double-step. That is $\mu(\mathrm{row}_2 B) = 2$ and $\mu(\mathrm{row}_2 B) = 2$ which contradicts the strict inequality $\mu(\mathrm{row}_2 B) < \mu(\mathrm{row}_2 B)$

$$B \;=\; \begin{pmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \\ 0 & 1 & 1 & 1 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

(4.28) Example:
If a system of linear equations is in Gauss form, then it is truly possible to solve this system. As an example, let us consider the following system

$$\begin{pmatrix} 0 & 1 & 2 & -3 & 1 \\ 0 & 0 & 1 & -4 & 5 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix} x \;=\; \begin{pmatrix} -5 \\ 7 \\ 2 \\ 0 \end{pmatrix}$$

Written explicitly - where we denote $x = (x_1, x_2, x_3, x_4, x_5)$ as usual - this system abbreviates the following set of equations

$$\begin{array}{lrcl} (1) & x_2 + 2x_3 - 3x_4 + x_5 & = & -5 \\ (2) & x_3 - 4x_4 + 5x_5 & = & 7 \\ (3) & x_5 & = & 2 \\ (4) & 0 & = & 0 \end{array}$$

First of all it is clear that equation (4) is a void condition, the set $\mathbb{L}$ of solutions is solely determined by equations (1) to (3). This would have been entirely different, if we had the equation $0 = 1$, in this case we had $\mathbb{L} = \emptyset$, as there would be no specific solution u. Also the variable x_1 does not occur in the system at all - due to $\mathrm{col}_1(A) = 0$. Consequently the set $\mathbb{L}$ of solutions will be of the form $R \times L$ for some subset $L \subseteq R^4$.
Let us now turn our attention to solving this system: In this case we already know $x_5 = 2$ and this allows to deduce $x_3 = 7 + 4x_4 - 5x_5 = -3 + 4x_4$ from equation (2). This again can be used in equation (1) to obtain $x_2 = -5 - 2x_3 + 3x_4 - x_5 = -7 - 2(-3 + 4x_4) + 3x_4 = -1 - 5x_4$. Altogether the solutions x are of the form

$$x \;=\; \begin{pmatrix} x_1 \\ -1 - 5x_4 \\ -3 + 4x_4 \\ x_4 \\ 2 \end{pmatrix} \;=\; \begin{pmatrix} 0 \\ -1 \\ -3 \\ 0 \\ 2 \end{pmatrix} + x_1 \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix} + x_4 \begin{pmatrix} 0 \\ -5 \\ 4 \\ 1 \\ 0 \end{pmatrix}$$

So, as could have been expected from (4.23), the set of solutions $\mathbb{L}$ is of the form $\mathbb{L} = u + K$ where $u = (0, -1, -3, 0, 2)$ is a specific solution to the system and K is the kernel of A, here K is a (rank 2) sub-module of R^5.

(4.29) Lemma: (viz. 848) **Gaussian Algorithm**
Let $(R, +, \cdot)$ be a commutative ring, $1 \leq m$, $n \in \mathbb{N}$ and consider any $(m \times n)$-matrix $A = (a_{i,j}) \in \mathrm{mat}_{m,n}(R)$ over R. There is an $(m \times m)$-matrix $S \in \mathrm{mat}_m(R)$ that is a product of elementary matrices $S = S_1 \dots S_\ell$ where $S_k \in \mathrm{Elm}_m(R)$ such that

$$E \;:=\; S\,A \;\in\; \mathrm{mat}_{m,n}(R)$$

is in echelon-form. By remark (4.19) S thereby encodes operations on the rows of A. And this matrix S can be found using the following **Gaussian-algorithm**, that iterates on the number m of columns of A:

(1) *Initialisation:* Pick up a working matrix $E = (e_{i,j}) := A$ and begin with $S := \mathbb{1}_m$. The algorithm starts with row number $r := 1$.

(2) *Termination:* If the r-th row and all rows below that are zero (that is $\mathrm{row}_i(E) = 0$ for any $i \in r \dots m$), then E is in echelon form and hence we may terminate. Else we commence with step (3).

(3) *Targetting:* Among the r-th to last row of E seek out the row with the first non-zero entry, say this is the s-th row. To be precise we take

$$\begin{aligned} u &:= \min\{\, \mu(\mathrm{row}_v E) \mid v \in r \dots m \,\} \\ s &:= \min\{\, t \in r \dots m \mid \mu(\mathrm{row}_t E) = u \,\} \end{aligned}$$

(4) *The Pivot:* Swap the r-th and the s-th row of E, that is we move the row with the first non-zero entry up to the top row of our current step

$$\begin{aligned} S &:= P_{r,s} S \\ E &:= P_{r,s} E \end{aligned}$$

(5) *The Procedure:* Now, for any $i \in (r+1)\dots m$ proceed as follows: If $e_{i,u} = 0$ then ignore this i, else - if $e_{i,u} \neq 0$ - replace

$$\begin{aligned} S &:= T_{i,r}(-e_{i,u})\, D_i(e_{r,u})\, S \\ E &:= T_{i,r}(-e_{i,u})\, D_i(e_{r,u})\, E \end{aligned}$$

(6) *The Recursion:* Supposed $r < m$ consider the next row, that is replace $r := r+1$ and iterate to step (2). If $m = r$, then terminate the algorithm - E is in echelon-form. Note that step (2) may also terminate the algorithm. In any case we find $E = SA$ a matrix in echelon-form.

(4.30) Remark:

(i) Let us explain the Gaussian algorithm a bit: The main step (5) is where the actual computations are done. If we decode the operations of the elementary matrices they actually become quite simple: In fact for any $i \in (r+1)\dots m$ the algorithm simply multiplies row number i with $e_{r,u}$ and then subtracts $e_{i,u}$ times row number r, that is

$$\mathrm{row}_i E \;:=\; e_{r,u}(\mathrm{row}_i E) - e_{i,u}(\mathrm{row}_r E)$$

(ii) As the algorithm is iterated at most m times and the r-th iteration requires at most $m-r$ row-operations (as described in (i) above) the algorithm needs a total of at most $m(m-1)/2$ row-operations.

(iii) If R is a field, then $\mathrm{Elm}_m(R) \subseteq \mathrm{gl}_m(R)$ all elementary matrices are invertible and hence S is invertible, too, being a product of such matrices.

(iv) If R is a field, the matrix $E = (e_{i,j})$ in echelon form can easily be processed into a matrix G in Gauss-form: Let r be the number of non-zero rows of E, that is $r = \#\{\, i \in 1\dots m \mid \mathrm{row}_i E \neq 0 \,\}$. Further let $k(i) := \mu(\mathrm{row}_i E) \in 1\dots n$ and $e_i := e_{i,k(i)}$ and

$$\begin{aligned} D &:= \mathrm{dia}\left(\frac{1}{q_1}, \dots, \frac{1}{q_r}, 1, \dots, 1\right) \\ G &:= DE \end{aligned}$$

Then G is in Gauss-form, $T = DS$ is a product of elementary matrices still, and $G = TA$. And as we will see in (v) this allows to solve the system of linear equations $Ax = b$.

(v) Suppose we are given a system of linear equations $Ax = b$ over a field R. We then use the Gaussian algorithm and (iv) to find a matrix $T \in \mathrm{gl}_m R$ such that $G = TA$ is in Gauss form. Then by (4.23) the set of solutions of $Ax = b$ is given to be:

$$\mathbb{L}(Ax = b) \;=\; \mathbb{L}(Gx = Tb)$$

Hence it remains to solve the equation $Gx = Tb$. But as $G = (g_{i,j})$ is in Gauss form this is feasible: also refer to the example above.

For a more formal approach let us denote the number of non-zero rows of G by $r \in 0 \dots m$, that is $r := \#\{\, i \in 1 \dots m \mid \mathrm{row}_i G \neq 0 \,\}$. Also let $k(i) := \mu(\mathrm{row}_i G) \in 1 \dots n$ and $g_i := g_{i,k(i)}$ again. Then we we can iteratively compute the solution beginning with $i = r$ down to $i = 1$

$$x_{k(i)} \;=\; [Tb]_i - \sum_{j=k(i)+1}^{n} g_{i,j} x_j$$

Thereby all the variables $\{\, x_1, \dots, x_n \,\} \setminus \left\{\, x_{k(1)}, \dots, x_{k(r)} \,\right\}$ remain undetermined. That is any choice of these variables produces a solution, whereas the variables $x_{k(1)}, \dots, x_{k(r)}$ are determined by these indeterminates. In other words the kernel of G is $(n-r)$-dimensional subspace of R^n and the set of solutions is of the form

$$\mathbb{L}(Ax = b) \;=\; u + \mathrm{kn}(G)$$

(vi) It might be helpful to reformulate the Gaussian algorithm in pseudo-code, so that's what we want to do now: First of all we will need the following variables: $A = (a_{i,j})$ and $E = (e_{i,j}) \in \mathrm{mat}_{n,m} R$, $S = (s_{i,j}) \in \mathrm{mat}_m(R)$ also i, r, s and $u \in \mathbb{N}$ and finally swap $\in R^n$.

```
S ← 𝟙_m
E ← A
r ← 1
while (r < m) and (∃ s ∈ r ... m : row_s(E) ≠ 0) do begin
    u ← min{ μ(row_v(E)) | v ∈ r ... m }
    s ← min{ t ∈ r ... m | μ(row_t(E)) = u }
    if (s ≠ r) then begin
        swap ← row_r(E)
        row_r(E) ← row_s(E)
        row_s(E) ← swap
    end-if
    for i := r + 1 to m step 1 do begin
        row_i(S) ← s_{r,u}(row_i(S)) − s_{i,u}(row_r(S))
        row_i(E) ← e_{r,u}(row_i(E)) − e_{i,u}(row_r(E))
    end-for
    r ← r + 1
end-while
```

(4.31) Example:
We would like to enlighten things a little, by presenting an example of the workings of the Gaussian algorithm in the case of the following example

$$A \;=\; \begin{pmatrix} 0 & 1 & 2 & -3 & 1 \\ 0 & 1 & 4 & -7 & 6 \\ 0 & 2 & 4 & -6 & 2 \\ 0 & -1 & 1 & 3 & 0 \end{pmatrix}$$

First of all the Gauss-algorithm initializes $E := A$, $S := \mathbb{1}_m$ and starts with row $r = 1$ now, as A is non-zero the algorithm does not terminate right away. As the 1-st column of E has a minimal non-zero entry we get $u = 2$ and $s = 1$. Now as $r = s$ there is no need to pivot (we have $e_{2,1} = 1 \neq 0$).

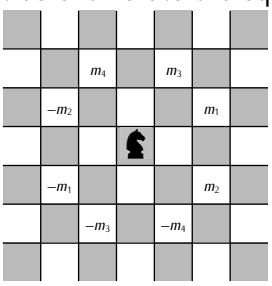
In the central step, for $i = 2$, we get $S = T_{2,1}(-1)\, D_2(1)$ and multiply E with $T_{2,1}(-1)\, D_2(1)$ from the left. That is the 2-nd row is multiplied with 1 (which changes nothing) and then -1 times the 1-st row is added to the 2-nd row. Likewise for $i = 3$ we multiply with $T_{3,1}(-2)\, D_3(1)$ from the left again. That is the 3-rd row is multiplied with 1 (void again) and then -2 times the 1-st row is added to the 3-rd row. Finally for $i = 4$ we multiply with $T_{4,1}(1)\, D_4(1)$ from the left, that is we add the 1-st row to the 4-th row. So far we've got $S = T_{4,1}(1)\, D_4(1)\, T_{3,1}(-2)\, D_3(1)\, T_{2,1}(-1)\, D_2(1)$ and $E = SA$ which amounts to

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ -1 & 1 & 0 & 0 \\ -2 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 0 & 1 & 2 & -3 & 2 \\ 0 & 1 & 4 & 8 & -4 \\ 0 & 2 & 4 & 0 & 1 \\ 0 & -1 & -2 & 3 & 0 \end{pmatrix} = \begin{pmatrix} 0 & 1 & 2 & -3 & 2 \\ 0 & 0 & 2 & -4 & 5 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 3 & 0 & 1 \end{pmatrix}$$

Now the Gauss-algorithm iterates with $r = 2$. The first column with non-zero entries (from row 2 on) is $s = 2$ with $u = 3$, so again there is no need to pivot ($e_{3,2} = 2 \neq 0$). However for $i = 3$ we find $e_{3,2} = 0$ and hence we continue with $i = 4$ already. Hereby we multiply with $T_{4,2}(-3)\, D_4(2)$ from the left which is: First multiply row 4 with 2 and then add -3 times the second row to row 4. So S has risen to $S = T_{4,2}(-3)\, D_4(2)\, T_{4,1}(1)\, T_{3,1}(-2)\, T_{2,1}(-1)$ (omitting identity matrices) and this step yielded the matrices

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & -3 & 0 & 2 \end{pmatrix} \begin{pmatrix} 0 & 1 & 2 & -3 & 2 \\ 0 & 0 & 2 & -4 & 5 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 3 & 0 & 1 \end{pmatrix} = \begin{pmatrix} 0 & 1 & 2 & -3 & 2 \\ 0 & 0 & 2 & -4 & 5 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 12 & -13 \end{pmatrix}$$

As we have a zero-row $\mathrm{row}_3 E = 0$ the following step $r = 3$ will be the last one to take. But let's stick to the letter: Here we get $u = 4$ and $s = 4$ so we have to swap rows 3 and 4 by multiplying $P_{3,4}$ from the left. So by now we found the matrices



$$S = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & -3 & 0 & 2 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 & 0 \\ -1 & 1 & 0 & 0 \\ -2 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ -1 & 1 & 0 & 0 \\ 5 & -3 & 0 & 2 \\ -2 & 0 & 1 & 0 \end{pmatrix}$$

$$E = \begin{pmatrix} 1 & 0 & 0 & 0 \\ -1 & 1 & 0 & 0 \\ 5 & -3 & 0 & 2 \\ -2 & 0 & 1 & 0 \end{pmatrix} \begin{pmatrix} 0 & 1 & 2 & -3 & 1 \\ 0 & 1 & 4 & -7 & 6 \\ 0 & 2 & 4 & -6 & 2 \\ 0 & -1 & 1 & 3 & 0 \end{pmatrix} = \begin{pmatrix} 0 & 1 & 2 & -3 & 1 \\ 0 & 0 & 2 & -4 & 5 \\ 0 & 0 & 0 & 12 & -13 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}$$

In step $r = 4$ we see that $\mathrm{row}_4 E = 0$ already, hence the termination condition (2) of the Gaussian algorithm is satisfied. And in fact, we see that E is in echelon-form already.

Note that this does not represent the modified linear system of equations that we computed in the introductory example. The reason is that in the manual computation we have evaded the common multiple of 2 in the first step $(2) - (1) \to (2)$. But the Gauss-algorithm does not check for common multiples.

(4.32) Example:
Here's a complimentary example for those chess-players out there: Let us consider a knight on a chess-board (of infinite size). We want to know, whether it can reach any square and what the redundancies are, when moving this chess piece. So let us enumerate the squares the knight may move to

If it starts at $(0,0)$ the valid movements are $m_1 = (2,1)$, $m_2 = (2,-1)$, $m_3 = (1,2)$ and $m_4 = (-1,2)$. We only need to count the number of times the knight is moved in the directions m_1 to m_4, as the sequel of moves has no impact on the end location. Altogether the possible locations the knight may move to are the image of the following matrix

$$M \;=\; \begin{pmatrix} 2 & 2 & 1 & -1 \\ 1 & -1 & 2 & 2 \end{pmatrix}$$

As $M(-1,1,1,0) = (1,0)$ and $M(0,-1,1,-1) = (0,1)$ we see, that the knight may reach any square on the chess board, given time. So if we want to reach square (x,y) we can use the number n_i of moves in direction m_i given by $(n_1,n_2,n_3,n_4) = (-x, x-y, x+y, -y)$. We will prove shortly that the kernel of M is the following:

$$\mathrm{kn}(M) \;=\; \mathbb{Z}\begin{pmatrix} 1 \\ 1 \\ -2 \\ 2 \end{pmatrix} + \mathbb{Z}\begin{pmatrix} 0 \\ 4 \\ -3 \\ 5 \end{pmatrix}$$

So these are the non-trivial moves, that return the knight to its starting location (e.g. a trivial move would be m_1, m_2, $-m_1$, $-m_2$). Combining all this with (4.23.(i)) we see that the possible numbers $n = (n_1,n_2,n_3,n_4)$ of moves to take the knight to square (x,y) are

$$\mathbb{L}\left(Mn = \begin{pmatrix} x \\ y \end{pmatrix}\right) \;=\; \begin{pmatrix} -x \\ x-y \\ x+y \\ -y \end{pmatrix} + \mathbb{Z}\begin{pmatrix} 1 \\ 1 \\ -2 \\ 2 \end{pmatrix} + \mathbb{Z}\begin{pmatrix} 0 \\ 4 \\ -3 \\ 5 \end{pmatrix}$$

Prob It is easy to verify $(a, a+4b, -2a-3b, 2a+5b) \in \mathrm{kn}(M)$ for any a, $b \in \mathbb{Z}$. Conversely consider $n \in \mathrm{kn}(M)$ and let $a := n_1$. As $n_3 + n_4 = (n_3 - n_4) + 2n_4 = -2(n_1+n_2) + 2n_4$ we have $2 \mid n_3 + n_4$. As also $n_2 - n_1 = 2(n_3+n_4)$ we get $4 \mid n_2 - n_1$. Let $b := (n_2 - n_1)/4$ then $n_2 = a + 4b$. Eliminating n_4 from M we get $5n_1 + 3n_2 + 4n_3 = 0$ and from this $n_3 = -2a - 3b$. Eliminating n_3 from M we get $3n_1 + 5n_2 - 4n_4 = 0$ and hence also $n_4 = 2a + 5b$.

Let us close this section with another algorithm to solve SLEs with an equal number of variables and equations over a field. This is a rather common situation and this algorithm is particularly useful, if you need to solve $Ax = b$ for lots of different b. However it also requires A to be an invertible matrix:

(4.33) Proposition: (viz. 849)
Let $(F, +, \cdot)$ be a field and $A \in \mathrm{gl}_{n+1}(F)$ an invertible, square matrix over F. Then there are matrices P_1 to P_n and L_1 to L_n all in $\mathrm{mat}_{n+1}(F)$ satisfying the following three properties

(1) Any P_k (where $1 \leq k \leq n$) is the permutation matrix of a transposition of the form $(k\, q(k))$, that is $P_k = P_{(k\, q(k))}$, where $k \leq q(k) \leq n+1$. In particular $P_k^2 = \mathbb{1}_{n+1}$.

(2) Any L_k (where $1 \leq k \leq n$) is $\mathbb{1}_{n+1}$ augmented by some entries on the k-th column, below the diagonal. That is $\mathrm{ent}_{i,j}(L_k) = 1$ for $i = j$ and for $i \neq j$ we have: $\mathrm{ent}_{i,j}(L_k) = 0$ whenever $j \neq k$ or $i < k$. In particular $L_k^* \in \mathrm{tri}_n^1(F)$ such that L_k is invertible.

(3) The matrix $U := L_n P_n \ldots L_2 P_2 L_1 P_1 A \in \mathrm{tri}_n(F)$ is an upper triangular matrix.

For any $k \in 1 \ldots n$ let us denote $\widehat{L}_k := P_n \ldots P_{k+1} L_k P_{k+1} \ldots P_n$, then the $\widehat{L}_k$ are of the same shape, as L_k (as described in (2) above). Let us also denote the permutation matrix $P := P_n \ldots P_2 P_1$ and likewise $\widehat{L} := \widehat{L}_n \ldots \widehat{L}_2 \widehat{L}_1$. Then we have $\widehat{L}^* \in \mathrm{tri}_{n+1}^1(F)$ and we can rewrite the equation in (3) in the form

$$U \;=\; \widehat{L}PA \;\in\; \mathrm{tri}_{n+1}(F)$$

(4.34) Remark:

(i) By property (2) above, any L_k is $\mathbb{1}_{n+1}$ up to entries on the k-th column below the diagonal. In the proof we will use the term *lower-k-columns-only* for matrices of this kind. The same is true for $\widehat{L}_k$ as it is just L_k subjected to a permutation of these lower-k-column entries

$$L_k \;=\; \begin{pmatrix} 1 & & & & \\ & \ddots & & & \\ & & 1 & & \\ & & \ell_{k+1,k} & 1 & \\ & & \vdots & & \ddots \\ & & \ell_{n+1,k} & & 1 \end{pmatrix}$$

(ii) This allows to compute the solution x of the SLE $Ax = b$: The proposition grants an upper triangular matrix U, a lower triangular matrix L and a permutation matrix P such that $U = LPA$. Therefore we can compute the solution $x \in F^{n+1}$ in the following way:

- compute $y := \widehat{L}Pb$
- solve $Ux = y$ for x, using (4.14)

Prob as both P and $\widehat{L}$ are invertible $Ax = b$ is equivalent to $\widehat{L}PAx = \widehat{L}Pb$ and this is $Ux = y$.

(iii) *LU-decomposition*: As $\widehat{L}$ only has 1 on its diagonal, its determinant is $\det(L) = 1$ and thereby $\widehat{L}^{-1} = \widehat{L}^{\#}$. Clearly $\widehat{L}^{\#}$ is a lower triangular matrix with all 1 on the diagonal, again. And from $U = \widehat{L}PA$ we then get the decomposition of PA

$$PA \;=\; \widehat{L}^{-1}\,U$$

That is we have found an upper triangular matrix $U \in \mathrm{tri}_{n+1}(F)$ and a lower triangular matrix $L := \widehat{L}^{-1}$ such that $L^* \in \mathrm{tri}^1_{n+1}(F)$ and A is decomposed into L and U, up to permutation P.

(iii) Let us present some pseudo-code for how to compute the P_k, L_k and U of proposition (4.33) for a given matrix $A \in \mathrm{gl}_{n+1}(F)$. Note that the choice of $q(k)$ is arbitrary, for computations by hand it might be best to watch out for divisibilities. Considering numeric stability in a computer algebra programs it is advisible to pick the $q(k)$ such that $|[U]_{q(k),k}|$ is maximal.

$U \leftarrow A$
for $(k = 1)$ to n do begin
 choose $q(k) \in k \ldots n+1$ such that $\mathrm{ent}_{q(k),k}(U) \neq 0$
 $L_k \leftarrow \mathbb{1}_{n+1}$
 $P_k \leftarrow P_{(q(k)\,k)}$
 swap $\leftarrow \mathrm{row}_k(U)$
 $\mathrm{row}_k(U) \leftarrow \mathrm{row}_{q(k)}(U)$
 $\mathrm{row}_{q(k)}(U) \leftarrow$ swap
 for $(i = k+1)$ to $(n+1)$ do begin
 $\mathrm{ent}_{i,k}(L_k) \leftarrow -\mathrm{ent}_{i,k}(U) \cdot \mathrm{ent}_{k,k}(U)^{-1}$
 $\mathrm{row}_i(U) \leftarrow \mathrm{row}_i(U) + \mathrm{ent}_{i,k}(L_k) \cdot \mathrm{row}_k(U)$
 end-for
end-for

(iv) The best way to track and compute this algorithm is to use a tableau of the following form: Note that the method, how to get L_k from $P_k U_{k-1}$, is described in the algorithm above

k	τ	U_{k-1}	P_k	$P_k U_{k-1}$	L_k
1	$(1\ q(1))$	$U_0 = A$	$P_{(1\,q(1))}$	$P_1 U_0$	L_1
2	$(2\ q(2))$	$L_1 P_1 U_0$	$P_{(2\,q(2))}$	$P_2 U_1$	L_2
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$
n	$(n\ q(n))$	$L_{n-1} P_{n-1} U_{n-2}$	$P_{(n\,q(n))}$	$P_n U_{n-1}$	L_n
$n+1$		$U = L_n P_n U_{n-1}$			

(v) Recall the (4×4)-matrix that we inverted at the end of section 4.1 and take it for A. If we choose $q(1) = 2$, $q(2) = 3$ and $q(3) = 4$ that is $P_1 = P_{(1\,2)}$, $P_2 = P_{(2\,3)}$ and $P_3 = P_{(3\,4)}$ respectively, then the LU-algorithm above turns A into the form $U = \widehat{L}PA$, which becomes

$$\begin{pmatrix} 1 & -1 & 3 & 3 \\ 0 & -1 & 2 & 1 \\ 0 & 0 & 2 & 5 \\ 0 & 0 & 0 & 0.5 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 2 & -1 & 1 & 0 \\ -1 & 0.5 & 1.5 & 1 \end{pmatrix} \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} 4 & -2 & 5 & 3 \\ 1 & -1 & 3 & 3 \\ 0 & -1 & 2 & 1 \\ -2 & 1 & -2 & 0 \end{pmatrix}$$

4.4 Matrix Representations

As we have seen so far, matrices do provide two things: They can be used to formalize and solve linear systems of equations and they enable us to study explicit examples of linear maps. In short they allow computations in module theory of modules of the form R^n. However a finitely generated, free R-modules always is *isomorphic* to such an R-module. So in this section we address the topic how to pull general module theory (of finitely generated, free R-modules) into the computational range of matrices.
To do this we clearly have to fix an isomorphism $M \xrightarrow{\sim} R^n$ by choosing an R-basis $\mathcal{M} = \{ m_1, \ldots, m_n \}$. But this alone does not suffice: As bases are sets only, we have to decide which element of the basis corresponds to the first coordinate, which to the second and so on. That is we have to fix a certain order on the basis $\mathcal{M}$ - otherwise the isomorphsim $M \xrightarrow{\sim} R^n$ is only determined up to permutations of basis elements. That is, instead of a set $\mathcal{M} = \{ m_1, \ldots, m_n \} \subseteq M$ we have to fix a tuple $\mathcal{M} = (m_1, \ldots, m_n)$. So let us recall the definition of an ordered basis:

(4.35) Definition:
Let $(R, +, \cdot)$ be an arbitrary ring and M be an R-module. Then an n-tuple $\mathcal{M} = (m_1, \ldots, m_n)$ where $1 \leq n \in \mathbb{N}$ and $m_i \in M$ is said to be an **(finite) ordered R-basis** of M, iff it satisfies

(1) $\{ m_1, \ldots, m_n \} \subseteq M$ is an R-basis of M

(2) the m_i are pairwise distinct: $m_i = m_j \implies i = j$

(4.36) Remark:

(i) By definition any R-module M, that has a basis is called *free*, but most modules aren't. Hence an R-module M only has an ordered basis, iff it is both, free and finitely generated.

If R is commutative or a skew-field, then the number n of basis elements is uniquely determined however - refer to (3.100). And this number n has been called the *dimension* of M

$$n \;=\; \dim(M)$$

(ii) The standard basis of R^n itself is the so-called *Euclidean basis* $\mathcal{E}(n) := \{ e_1, \ldots, e_n \}$ where for any $j \in 1 \ldots n$ we chose $e_j = (\delta_{i,j}) \in R^n$. Written explicitly that is

$$\begin{aligned} e_1 &= (1,0,0,\ldots,0,0) \\ e_2 &= (0,1,0,\ldots,0,0) \\ \vdots &\quad\; \vdots \\ e_n &= (0,0,0,\ldots,0,1) \end{aligned}$$

By abuse of notation we denote the *ordered* basis $\mathcal{E}(n) := (e_1, \ldots, e_n)$ composed of these Euclidean vectors, by the same symbol $\mathcal{E}(n)$ or simply by $\mathcal{E}$. This should not cause any problems, however.

(4.37) Definition:
Let $(R,+,\cdot)$ be a ring and M, N be R-modules again. Also fix some ordered basis $\mathcal{M} = (m_1,\ldots,m_s) \subseteq M$ and $\mathcal{N} = (n_1,\ldots,n_r) \subseteq N$ of M and N respectively. If now $x \in M$ then we denote

$$[x]_{\mathcal{M}} \;:=\; (x_1,\ldots,x_s) \;\in\; R^s \quad \text{where} \quad x \;=\; \sum_{j=1}^{s} x_j\, m_j$$

and $[x]_j := x_j \in R$, the j-th coefficient of x with respect to the basis $\mathcal{M}$. Also if $\varphi : M \to N$ is a homomorphism of R-modules, then we define the $(r \times s)$-matrix (where $i \in 1\ldots r$ and $j \in 1\ldots s$)

$$[\varphi]^{\mathcal{N}}_{\mathcal{M}} \;:=\; \Big(\big[\varphi(m_j)\big]_i \Big) \;\in\; \mathrm{mat}_{r,s}(R)$$

(4.38) Remark:

(i) Let us give an alternative definition of the matrix representation of φ: The coefficients $a_{i,j} \in R$ of $[\varphi]^{\mathcal{N}}_{\mathcal{M}} = (a_{i,j})$ are the representations of $\varphi(m_j)$ in terms of the basis $\mathcal{N}$. And thereby the coefficients $a_{i,j}$ are defined by the property

$$\varphi(m_j) \;=\; \sum_{i=1}^{r} a_{i,j}\, n_i$$

That is the j-th column of $[\varphi]^{\mathcal{N}}_{\mathcal{M}}$ is the basis representation of the image of the j-th basis vector of M in terms of the chosen basis of N

$$[\varphi]^{\mathcal{N}}_{\mathcal{M}} \;:=\; \begin{pmatrix} | & & | \\ [\varphi(m_1)]_{\mathcal{N}} & \cdots & [\varphi(m_s)]_{\mathcal{N}} \\ | & & | \end{pmatrix}$$

(ii) In case of an endomorphism $\varphi : M \to M$ where we fix the same ordered basis $\mathcal{M}$ on both the preimage M and image M we just write

$$[\varphi]_{\mathcal{M}} \;:=\; [\varphi]^{\mathcal{M}}_{\mathcal{M}}$$

And if the bases $\mathcal{M}$ of M and $\mathcal{N}$ of N are understood, we will often simplify the notation by omitting the bases names, that is we write $[x]$ instead of $[x]_{\mathcal{M}}$ and $[\varphi]$ instead of $[\varphi]^{\mathcal{N}}_{\mathcal{M}}$.

(iii) In case $M = R^s$ there is no difference between the element $x \in M$ itself and its representation in terms of the ordered Euclidean basis $\mathcal{E}(s)$: Consider $x = (x_1,\ldots,x_s) \in R^s$ then clearly $x = \sum_j x_j e_j$ and thereby x is precisely its representation in this basis

$$x \;=\; [x]_{\mathcal{E}(s)}$$

(4.39) Example:
As an example let us regard the polynomial ring $R[t]$ as an R-module. Clearly $R[t]$ is free, as its basis is given by the monomials $\{ t^k \mid k \in \mathbb{N} \}$. The *derivative* $\partial : R[t] \to R[t]$ is the following map

$$\partial \left(\sum_{k=0}^{\infty} a_k \, t^k \right) \; := \; \sum_{k=1}^{\infty} k a_k \, t^{k-1} \; = \; \sum_{k=0}^{\infty} (k+1) a_{k+1} \, t^k$$

In order to give a matrix representation of the map ∂ we have have to restrict ourselves to a finitely generated sub-module of $R[t]$. That is we fix a number $n \in \mathbb{N}$ and regard the R-module of polynomials of degree up to n.

$$M \; := \; \{ f \in R[t] \mid \deg(f) \leq n \}$$

Note that this no longer is a ring, as it is no longer closed under multiplication. It still is closed under addition and scalar multiplication and hence an R-module. It stands to reason to pick up the following ordered basis of M: $\mathcal{T} := (1, t, t^2, \ldots, t^n)$. Then M is isomorphic to R^{n+1} under the isomorphism

$$R^{n+1} \; \xrightarrow{\sim} \; M \; : \; (a_0, a_1, \ldots, a_n) \mapsto \sum_{k=0}^{n} a_k \, t^k$$

And as $\partial(t^k) = k t^{k-1}$ maps one base element to a multiple of another, the derivative $\partial : M \to M$ has the following matrix representation with respect to this ordered basis $\mathcal{T}$:

$$[\partial] \; = \; \begin{pmatrix} 0 & 1 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 2 & 0 & \cdots & 0 \\ 0 & 0 & 0 & 3 & & 0 \\ \vdots & \vdots & \vdots & & \ddots & \\ 0 & 0 & 0 & 0 & \cdots & n-1 \\ 0 & 0 & 0 & 0 & \cdots & 0 \end{pmatrix}$$

(4.40) Lemma: (viz. 1024)
Let $(R, +, \cdot)$ be any ring, M be a finitely generated, free R-module and fix an ordered basis $\mathcal{M} \subseteq M$. Then $x \mapsto [x]_{\mathcal{M}}$ is R-linear, that is for any vectors $x, y \in M$ and some scalar $a \in R$ we get

$$\begin{aligned} [ax]_{\mathcal{M}} &= a \, [x]_{\mathcal{M}} \\ [x+y]_{\mathcal{M}} &= [x]_{\mathcal{M}} + [y]_{\mathcal{M}} \end{aligned}$$

Now consider another finitely generated, free R-module N and fix an ordered basis $\mathcal{N} \subseteq N$ again. Then $\varphi \mapsto [\varphi]_{\mathcal{M}}^{\mathcal{N}}$ is R-linear, as well, that is if φ and $\psi : M \to N$ are homomorphisms of R-modules, then

$$\begin{aligned} [a\varphi]_{\mathcal{M}}^{\mathcal{N}} &= a \, [\varphi]_{\mathcal{M}}^{\mathcal{N}} \\ [\varphi+\psi]_{\mathcal{M}}^{\mathcal{N}} &= [\varphi]_{\mathcal{M}}^{\mathcal{N}} + [\psi]_{\mathcal{M}}^{\mathcal{N}} \end{aligned}$$

Finally let L be a third finitely generated, free R-module and fix another ordered basis $\mathcal{L} \subseteq L$. For the following three equations we also require R to be commutative! If now $\varphi : L \to M$ and $\psi : M \to N$ are homomorphisms of R-modules and $x \in L$, then the composition of maps is compatible with the matrix multiplication, that is we find

$$\begin{aligned} [\varphi(x)]_{\mathcal{M}} &= [\varphi]_{\mathcal{L}}^{\mathcal{M}} [x]_{\mathcal{L}} \\ [\psi\varphi]_{\mathcal{L}}^{\mathcal{N}} &= [\psi]_{\mathcal{M}}^{\mathcal{N}} [\varphi]_{\mathcal{L}}^{\mathcal{M}} \end{aligned}$$

In particular, φ is an isomorphism, if and only if its matrix representation is invertible. In this case the matrix representation of φ^{-1} is precisely the inverse matrix of $[\varphi]_{\mathcal{M}}^{\mathcal{N}}$ formally

$$\left[\varphi^{-1}\right]_{\mathcal{N}}^{\mathcal{M}} = \left([\varphi]_{\mathcal{M}}^{\mathcal{N}}\right)^{-1}$$

Let $\mathcal{M} = (m_1, m_2, \ldots, m_s)$ and $\mathcal{N} = (n_1, n_2, \ldots, n_r)$, then the representation of a module homomorphism φ as a matrix $[\varphi]_{\mathcal{M}}^{\mathcal{N}}$ is an isomorphism in itself, from the R-module $\mathrm{mhom}(M, N)$ to the R-module $\mathrm{mat}_{r,s}(R)$. That is we find the following isomorphy

$$\mathrm{mhom}(M, N) \xrightarrow{\sim} \mathrm{mat}_{r,s}(R) \ : \ \varphi \mapsto [\varphi]_{\mathcal{M}}^{\mathcal{N}}$$

The inverse map can be constructed as follows: Given $A \in \mathrm{mat}_{r,s}(R)$ then we need to define $\varphi_A : M \to N$ such that $[\varphi_A]_{\mathcal{M}}^{\mathcal{N}} = A$. For $x \in M$ we have $[x]_{\mathcal{M}} \in R^s$ and hence $A[x]_{\mathcal{M}} \in R^r$ such that we may take

$$\varphi_A(x) := \sum_{i=1}^{r} [A[x]_{\mathcal{M}}]_i \, n_i$$

(4.41) Remark:
Let L and M be R-modules and fix the ordered bases $\mathcal{L} = (\ell_1, \ldots, \ell_t)$ and $\mathcal{M} = (m_1, \ldots, m_s)$ respectively. Let also $\varphi : L \to M$ be an R-module-homomorphism and denote its matrix representation concerning these bases by $A = [\varphi] \in \mathrm{mat}_{s,t}(R)$. If now $x \in L$ is a vector, then the property $[\varphi(x)] = [\varphi][x]$ is just the commutativity of the following diagram:

$$\begin{array}{ccccc} & x & \longmapsto & \varphi(x) & \\ x & L & \longrightarrow & M & y \\ \downarrow & \updownarrow & \circlearrowleft & \updownarrow & \downarrow \\ [x] & R^t & \longrightarrow & R^s & [y] \\ & u & \longmapsto & Au & \end{array}$$

And if N is another R-module with the ordered R-basis $\mathcal{N} = (n_1, \ldots, n_r)$ and $\psi : M \to N$ is another homomorphism of R-modules having the matrix representation $B = [\psi] \in \mathrm{mat}_{r,s}(R)$, then the property $[\psi\varphi] = [\psi][\varphi]$ is just another commutative diagram:

$$\begin{array}{ccccc} L & \xrightarrow{\varphi} & M & \xrightarrow{\psi} & N \\ \updownarrow & \circlearrowleft & \updownarrow & \circlearrowleft & \updownarrow \\ R^t & \underset{A}{\longrightarrow} & R^s & \underset{B}{\longrightarrow} & R^r \end{array}$$

(4.42) Corollary: (viz. 1026)
Let $(R,+,\cdot)$ be a commutative ring and consider two R-modules M and N which are free and finitely generated and let $s := \dim(M)$ and $r := \dim(N)$. Then we obtain the following statements:

(i) Let $\varphi : M \to N$ be a homomorphism of R-modules. Then the following three statements are equivalent (and in this case we already have $r = s$, of course)

 (a) φ is invertible (i.e. bijective)

 (b) There are some ordered bases $\mathcal{M}$ of M and $\mathcal{N}$ of N such that the matrix $[\varphi]^{\mathcal{N}}_{\mathcal{M}}$ is invertible.

 (c) For any two ordered bases $\mathcal{M}$ of M and $\mathcal{N}$ of N we find that the matrix $[\varphi]^{\mathcal{N}}_{\mathcal{M}}$ is invertible.

(ii) If $A \in \mathrm{mat}_s(R)$ is a square matrix, then the following two statements concerning A are equivalent

 (a) A is invertible

 (b) There are ordered bases $\mathcal{M}$, $\mathcal{M}'$ of M such that A is the matrix representation $A = [\mathbb{1}_M]^{\mathcal{M}'}_{\mathcal{M}}$ of the identity map $\mathbb{1}_M$ on M.

(iii) If $\mathcal{M} = (m_1, \ldots, m_s)$ is an ordered basis of M and $T = (t_{i,j}) \in \mathrm{mat}_s(R)$ is an invertible matrix, then we obtain another ordered basis $\mathcal{M}' = (m'_1, \ldots, m'_s)$ of M by letting (for any $i \in 1 \ldots s$)

$$m'_j \;:=\; \sum_{i=1}^{s} t_{i,j}\, m_i$$

 Nota thereby T becomes the matrix of the change of base from $\mathcal{M}'$ to $\mathcal{M}$. That is T transfers $\mathcal{M}'$ to $\mathcal{M}$ in the following sense: $T = [\mathbb{1}_M]^{\mathcal{M}}_{\mathcal{M}'}$ and $T^{-1} = [\mathbb{1}_M]^{\mathcal{M}'}_{\mathcal{M}}$ respectively.

(iv) If $\mathcal{M}$ and $\mathcal{M}'$ are ordered bases of M, likewise $\mathcal{N}$ and $\mathcal{N}'$ are ordered bases of N and $\varphi : M \to N$ is any homomorphism of R-modules, then we let $S := [\mathbb{1}_M]^{\mathcal{M}}_{\mathcal{M}'} \in \mathrm{mat}_s(R)$ and $T := [\mathbb{1}_N]^{\mathcal{N}'}_{\mathcal{N}} \in \mathrm{mat}_r(R)$. Thereby both S and T are invertible matrices and we find

$$[\varphi]^{\mathcal{N}'}_{\mathcal{M}'} \;=\; T\,[\varphi]^{\mathcal{N}}_{\mathcal{M}}\,S$$

(v) If $\varphi : M \to M$ is an endomorphism of the module M and $\mathcal{M}$, $\mathcal{M}'$ are ordered bases of M, then for $T := [\mathbb{1}_M]^{\mathcal{M}'}_{\mathcal{M}} \in \mathrm{mat}_s(R)$ we find

$$[\varphi]_{\mathcal{M}'} \;=\; T\,[\varphi]_{\mathcal{M}}\,T^{-1}$$

(4.43) Definition: $(\diamondsuit)$
Let $(R,+,\cdot)$ be a commutative ring, M be a free, finitely generated R-module and $\varphi \in \mathrm{end}(M)$ be an endomorphism of M. Then we may define the **trace** and **determinant** of φ by picking up *any* ordered basis $\mathcal{M} \subseteq M$ and using the trace and determinant of the matrix representation of φ:

$$\begin{aligned} \mathrm{tr}(\varphi) &:= \mathrm{tr}\,([\varphi]_{\mathcal{M}}) \\ \det(\varphi) &:= \det\,([\varphi]_{\mathcal{M}}) \end{aligned}$$

Prob We need to prove the well-definedness, that is given another ordered basis $\mathcal{M}' \subseteq M$ and letting $A := [\varphi]_{\mathcal{M}}$ and $A' := [\varphi]_{\mathcal{M}'}$ we need to check that $\mathrm{tr}(A') = \mathrm{tr}(A)$ and $\det(A') = \det(A)$ yield the same result. But by (4.42.(v)) there is some $T \in \mathrm{gl}_n(R)$ such that $A' = TAT^{-1}$. Therefore by (4.8.(v)) we have $\mathrm{tr}(A') = \mathrm{tr}(TAT^{-1}) = \mathrm{tr}(ATT^{-1}) = \mathrm{tr}(A)$ and by (4.55.(ii)) also $\det(A') = \det(TAT^{-1}) = \det(T)\det(A)\det(T)^{-1} = \det(A)$.

(4.44) Definition:
Let $(R, +, \cdot)$ be a commutative ring and $1 \leq m, n \in \mathbb{N}$. Then two matrices A and $B \in \mathrm{mat}_{m,n}(R)$ are said to be **equivalent** iff there are invertible matrices $S \in \mathrm{gl}_m(R)$ and $T \in \mathrm{gl}_n(R)$ such that

$$A \sim B \quad :\Longleftrightarrow \quad B = SAT$$

Moreover two square matrices A, $B \in \mathrm{mat}_n(R)$ are said to be **similar** iff there is an invertible matrix $T \in \mathrm{gl}_n(R)$ such that

$$A \approx B \quad :\Longleftrightarrow \quad B = TAT^{-1}$$

(4.45) Corollary: (viz. 1028)
If $(R, +, \cdot)$ is a commutative ring, $1 \leq m, n \in \mathbb{N}$ and $A, B \in \mathrm{mat}_{m,n}(R)$ we get the following statements

(i) The equivalence $\sim$ of matrices is an equivalence relation on the set $\mathrm{mat}_{m,n}(R)$ of $(m \times n)$-matrices over R. Thereby $A \sim B$ are equivalent, if and only if there is R-linear map $\varphi : R^n \to R^m$ and there are some ordered bases $\mathcal{M}$, $\mathcal{M}'$ of R^m and $\mathcal{N}$, $\mathcal{N}'$ of R^n respectively, such that

$$A = [\varphi]_{\mathcal{N}}^{\mathcal{M}} \quad \text{and} \quad B = [\varphi]_{\mathcal{N}'}^{\mathcal{M}'}$$

(ii) The similarity $\approx$ of matrices is an equivalence relation on the set $\mathrm{mat}_n(R)$ of $(n \times n)$-matrices over R. Thereby $A \approx B$ are similar, if and only if there is R-linear map $\varphi : R^n \to R^n$ and there are some ordered bases $\mathcal{M}$ and $\mathcal{N}$ of R^n such that

$$A = [\varphi]_{\mathcal{M}} \quad \text{and} \quad B = [\varphi]_{\mathcal{N}}$$

(iii) If $B = SAT$ for some invertible matrices $S \in \mathrm{gl}_m(R)$ and $T \in \mathrm{gl}_n(R)$, then the kernel and image of A and B satisfy the following relations

$$\begin{aligned} \mathrm{im}(B) &= S\,\mathrm{im}(A) \\ \mathrm{kn}(B) &= T^{-1}\,\mathrm{kn}(A) \end{aligned}$$

(4.46) Proposition: (viz. 1029)
Let $(R, +, \cdot)$ be a commutative ring and let M be a (free, finitely generated) R-module having the ordered basis $\mathcal{M} = (m_1, \ldots, m_n) \subseteq M$. Finally consider $\varphi \in \mathrm{end}(M)$ an R-module endomorphism on M and let $A := [\varphi]_{\mathcal{M}}$ be the matrix representation of φ. Then the following statements are not much of a surprise:

(i) Fix $r \in 1 \in 1 \ldots n$ and let $s := n - r$, consider the sub-module $P := \mathrm{Lh}\{\, m_1, \ldots, m_r \,\}$ and partition A into blocks the $A_{1,1} \in \mathrm{mat}_r(R)$, $A_{1,2} \in \mathrm{mat}_{r,s}(R)$, $A_{2,1} \in \mathrm{mat}_{s,r}(R)$ and finally $A_{2,2} \in \mathrm{mat}_s(R)$. That is A is decomposed into

$$A \;=\; \begin{pmatrix} A_{1,1} & A_{1,2} \\ A_{2,1} & A_{2,2} \end{pmatrix}$$

Then P is *invariant* under φ if and only if this block decomposition of A is upper triangular. Formally that is the following equivalence

$$\varphi(P) \;\subseteq\; P \quad\Longleftrightarrow\quad A_{2,1} \;=\; 0 \;\in\; \mathrm{mat}_{n-r,r}(R)$$

(ii) Let M^1, M^2, N^1 and N^2 all be R-modules having the ordered basis $\mathcal{M}^k = (m^k_1, \ldots, m^k_{r(k)}) \subseteq M^k$ and $\mathcal{N}^k = (n^k_1, \ldots, n^k_{s(k)}) \subseteq N^k$ respectively, where $k = 1$ or $k = 2$. We use these to build up ordered bases of $M := M^1 \oplus M^2$ and $N := N^1 \oplus N^2$ respectively:

$$\begin{aligned} \mathcal{M} &:= \Big((m^1_1, 0), \ldots, (m^1_{r(1)}, 0), (0, m^2_1), \ldots, (0, m^2_{r(2)}) \Big) \\ \mathcal{N} &:= \Big((n^1_1, 0), \ldots, (n^1_{s(1)}, 0), (0, n^2_1), \ldots, (0, n^2_{s(2)}) \Big) \end{aligned}$$

Also consider some R-module homomorphisms $\varphi_k : N^k \to M^k$ where $k = 1$ or $k = 2$ again. Then the basis representation of $\varphi_1 \oplus \varphi_2 : N \to M$ is the block diagonal matrix of basis representation of φ_1 and φ_2 respectively. In formal terms

$$[\varphi_1 \oplus \varphi_2]^{\mathcal{M}}_{\mathcal{N}} \;=\; \begin{pmatrix} [\varphi_1]^{\mathcal{M}^1}_{\mathcal{N}^1} & 0 \\ 0 & [\varphi_2]^{\mathcal{M}^2}_{\mathcal{N}^2} \end{pmatrix}$$

(iii) Recall that A is some matrix representation of the R-module endomorphism φ and consider any $r \in \mathbb{N}$ and $k(i) \in \mathbb{N}$ (where $i \in 1 \ldots r$) such that $\mathrm{rank}(M) = k(1) + \cdots + k(r)$. Then the following two statements are equivalent

(a) M is the inner direct sum of r free R-sub-modules $M_i \;\leq_{\mathrm{m}}\; M$ of $\mathrm{rank}(M_i) = k(i)$ that are invariant $\varphi(M_i) \subseteq M_i$ under φ, formally: $M \;=\; M_1 \oplus \cdots \oplus M_r$

(b) There are r square matrices $A_i \in \mathrm{mat}_{k(i)}(R)$ of size $k(i)$, such that A is similar to the block diagonal matrix of the A_i, formally: $A \;\approx\; A_1 \oplus \cdots \oplus A_r$

(4.47) Proposition: (viz. 1030)
Let $(R, +, \cdot)$ be a commutative ring and consider two R-modules M and N with the ordered bases $\mathcal{M} = (m_1, \ldots, m_s)$ of M and $\mathcal{N} = (n_1, \ldots, n_r)$ of N respectively. Then we obtain a 1-to-1 correspondence between the bilinear forms $b : M \oplus N \to R$ and the $(r \times s)$-matrices over R, given by

$$\begin{aligned} \{\, b : M \oplus N \to R \mid b \text{ is bilinear} \,\} &\longleftrightarrow \mathrm{mat}_{r,s}(R) \\ b &\mapsto \big(b(m_j, n_i)\big) \\ \Big((x, y) \mapsto \langle B[x]_{\mathcal{M}}, [y]_{\mathcal{N}} \rangle\Big) &\hookleftarrow B \end{aligned}$$

In case $M = N$ (and $\mathcal{M} = \mathcal{N}$) a bilinear form $b : M \oplus M \to R$ is said to be *symmetric*, iff for any x, $y \in M$ we have $b(x,y) = b(y,x)$. Likewise a matrix $B \in \mathrm{mat}_r(R)$ is said to be *symmetric* iff $B = B^*$. Now if $B = (b(m_j, m_i))$ is the matrix corresponding to the bilinear form b, then b is symmetric if and only if B is such:

$$b \text{ is symmetric} \quad \Longleftrightarrow \quad B \text{ is symmetric}$$

(4.48) Remark:
Note that *bilinear* means that $b : M \oplus N \to R$ is *multi-linear*, where the *bi-* refers to the fact that its preimage is composed of two modules. That is for any $a \in R$ and any x, $x' \in M$, y, $y' \in N$ we have $b(ax + x', y) = ab(x,y) + b(x',y)$ and $b(x, ay + y') = ab(x,y) + b(x,y')$. The word *form* is used for maps whose image lies in the base ring R again.

(4.49) Remark:
A map q of the form $q : M \oplus M \to R$ is said to be a *quadratic form* iff there is some bilinear form $b : M \oplus M \to R$ such that for any $x \in M$ we get $q(x) = b(x,x)$. Thus if we fix an ordered basis $\mathcal{M} = (m_1, \ldots, m_r)$ of M then this means that there is some matrix $B \in \mathrm{mat}_r(R)$ such that

$$q(x) \quad = \quad \langle B[x]_{\mathcal{M}}, [x]_{\mathcal{M}} \rangle$$

Thereby $B = (b_{i,j})$ is given to be $b_{i,j} = b(m_j, m_i)$. If we now take $u = (u_1, \ldots, u_r) \in R^r$ to be the basis representation $u = [x]_{\mathcal{M}}$ of $x \in M$ then we immediately find an explicit representation of q:

$$q(x) \quad = \quad \sum_{i=1}^{r} b_{i,i} u_i^2 + \sum_{i<j} (b_{i,j} + b_{j,i}) u_i u_j$$

In other words: If q is a quadratic form, then there are some coefficients $b_{i,j} \in R$ such that the above equation holds. And conversely for any $b_{i,j} \in R$ the above equation defines a quadratic form.

4.5 Determinants

In this section we will introduce the most fundamental notion of a *determinant*, $\det(A)$ of a square matrix A, which will be a criterion for the invertibility of A and hence the solvability of a square system of linear equations. In a more general setting the determinant is an example of *quantifier elimination*: We will find the equivalence

$$\exists\, B \in \mathrm{mat}_n(R) \;:\; AB = \mathbb{1}_n \quad \Longleftrightarrow \quad \det(A) \in R^*$$

Thereby the left-hand side of this equivalence contains an existential quantifier, thus it's hard to check, whether this property is satisfied. The right-hand side however contains no quantifiers and hence is straightforward to check. That's what makes the determinant so powerful.
But there's even more to the determinant: In the previous section we have introduced the Gauss-algorithm that can be used to solve systems of linear equations. This algorithm works like charm for any given SLE, but it can only be applied to one SLE at a time. It lacks a general theory of how the solution is obtained. Cramer's rule will be precisely this: A formula how the solution can be computed, an it will be formulated in terms of determinants. This theorem is the staging point for a lot of other powerful theorems, as it enables us to give computational answers to structural questions.
In order to see how all this comes about let us regard the most simple non-trivial system of linear equations, a system of size 2×2 in general form, say

$$\begin{aligned} a_{1,1}x_1 + a_{1,2}x_2 &= b_1 \\ a_{2,1}x_1 + a_{2,2}x_2 &= b_2 \end{aligned}$$

In this setting the determinant, Cramer's rule and everything else can be seen in an elementary way. The easiest way to solve this SLE is to multiply the upper equation by $a_{2,1}$ and the lower equation by $a_{1,1}$

$$\begin{aligned} a_{2,1}a_{1,1}x_1 + a_{2,1}a_{1,2}x_2 &= a_{2,1}b_1 \\ a_{1,1}a_{2,1}x_1 + a_{1,1}a_{2,2}x_2 &= a_{1,1}b_2 \end{aligned}$$

If R is a commutative ring we have $a_{2,1}a_{1,1} = a_{1,1}a_{2,1}$ and hence we eliminate the variable x_1 by subtracting the upper from the lower equation. This leaves

$$(a_{1,1}a_{2,2} - a_{2,1}a_{1,2})\, x_2 \;=\; a_{1,1}b_2 - a_{2,1}b_1$$

Here we have found the so-called *determinant* of A, it is the element $d := a_{1,1}a_{2,2} - a_{2,1}a_{1,2} \in R$. It can be computed for any 2×2 matrix and we will introduce the notation

$$\det \begin{pmatrix} a_{1,1} & a_{1,2} \\ a_{2,1} & a_{2,2} \end{pmatrix} \;:=\; a_{1,1}a_{2,2} - a_{2,1}a_{1,2}$$

Now, if d is an invertible element of R, then we have found a formula for the solution x_2 (and in complete analogy we find a similar formula for x_1).

$$\begin{aligned} x_1 &= d^{-1} \cdot (a_{2,2}b_1 - a_{1,2}b_2) &= d^{-1} \cdot \det \begin{pmatrix} b_1 & a_{1,2} \\ b_2 & a_{2,2} \end{pmatrix} \\ x_2 &= d^{-1} \cdot (a_{1,1}b_2 - a_{2,1}b_1) &= d^{-1} \cdot \det \begin{pmatrix} a_{1,1} & b_1 \\ a_{2,1} & b_2 \end{pmatrix} \end{aligned}$$

This already is Cramer's rule in the 2×2 case: The solution of a SLE can be expressed in terms of determinants. It can be generalized to SLEs of arbitrary size, but this will first require a generalization of the determinant for larger matrices. This is quite a strong result: If $d = a_{1,1}a_{2,2} - a_{2,1}a_{1,2}$ is invertible, then the whole matrix is invertible. And looking at the formulas for x_1 and x_2 above we even see the inverse matrix of A:

$$\begin{pmatrix} a_{1,1} & a_{1,2} \\ a_{2,1} & a_{2,2} \end{pmatrix}^{-1} = d^{-1} \cdot \begin{pmatrix} a_{2,2} & -a_{1,2} \\ -a_{2,1} & a_{1,1} \end{pmatrix}$$

More generally - if we ignore d for a minute - we have found another matrix (the so-called *adjugate* matrix) that is an inverse up to the determinant d as a factor

$$\begin{pmatrix} a_{1,1} & a_{1,2} \\ a_{2,1} & a_{2,2} \end{pmatrix} \begin{pmatrix} a_{2,2} & -a_{1,2} \\ -a_{2,1} & a_{1,1} \end{pmatrix} = d \cdot \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

So if $d \in R$ is a unit in R, then A has an inverse matrix. But the converse statement is true, as well: In case 2×2 it is a lengthy, but elementary computation, to show that $\det(AB) = \det(A) \cdot \det(B)$. We skip this, as we will prove it for determinants of any size. However if A has an inverse matrix A^{-1} it follows, that the determinant of A has to be a unit of R, since

$$1 = \det(\mathbb{1}_2) = \det(AA^{-1}) = \det(A) \cdot \det(A^{-1})$$

Thus we have proved the above equivalence for the case of 2×2 matrices. And along the way we have seen Cramer's rule and the adjugate matrix of a matrix.

In the general case of arbitrary size the arguments will follow precisely the same line, all we have to do is define the determinant and then prove that it has some nice properties that enable us to the same computations in the general setting.

For the definition we will require the notion of a permutation, though. This is a bijective map $\sigma : 1 \dots n \longleftrightarrow 1 \dots n$. We have already studied the group S_n of all permutations of n elements in section 1.2 and seen that this contains precisely $\#S_n = n!$ elements. Any permutation can be decomposed into transpositions. This decomposition is not unique, but the number of transpositions required always is either odd or even. In case of an even number we set $\operatorname{sgn}(\sigma) = 1$ and in case of an odd number we set $\operatorname{sgn}(\sigma) = -1$. This is the basis for the following definition:

(4.50) Definition:
Let $(R,+,\cdot)$ be a commutative ring and $1 \leq n \in \mathbb{N}$ a natural number. If now A is an $(n \times n)$-matrix having the coefficients

$$A \;=\; \begin{pmatrix} a_{1,1} & a_{1,2} & \dots & a_{1,n} \\ a_{2,1} & a_{2,2} & \dots & a_{2,n} \\ \vdots & & \ddots & \vdots \\ a_{n,1} & a_{n,2} & \dots & a_{n,n} \end{pmatrix}$$

then we define the **determinant** of A explicitly, to be the following element of R: (note that this definition makes sense, since the sum runs over the *finite* set S_n of all permutations on $1 \dots n$)

$$\det(A) \;:=\; \sum_{\sigma \in S_n} \operatorname{sgn}(\sigma) \prod_{i=1}^{n} a_{i,\sigma(i)}$$

(4.51) Example:
In case $n = 2$ there are precisely two permutations: the identity $\mathbb{1}$ and the transposition $(1\,2)$. Thereby the determinant has two summands only, in this case

$$\det(A) \;=\; a_{1,1}a_{2,2} - a_{1,2}a_{2,1}$$

In case $n = 3$ there are 6 permutations: The even permutations $\mathbb{1}$, $(1\,2\,3)$ and $(1\,3\,2)$ and the transpositions (hence odd permutations) $(1\,2)$, $(1\,3)$ and $(2\,3)$. Therefore - in this case - the determinant is given to be

$$\begin{aligned} \det(A) \;=\; & a_{1,1}a_{2,2}a_{3,3} + a_{1,2}a_{2,3}a_{3,1} + a_{1,3}a_{2,1}a_{3,2} \\ & -a_{1,2}a_{2,1}a_{3,3} - a_{1,3}a_{2,2}a_{3,1} - a_{1,1}a_{2,3}a_{3,2} \end{aligned}$$

Our last example will be $n = 4$: Here S_4 already contains $4! = 24$ permutations. Beyond that it would be tedious to try to write out the determinant explicitly and we have to use other means to evaluate it - namely the expansion theorems of Laplace. For $n = 4$ there are 12 even permutations: The identity $\mathbb{1}$, 8 3-cycles and 3 pairs of transpositions and another 12 odd permutations: 6 transpositions and 6 4-cycles, altogether:

$$\begin{aligned} \det(A) \;=\; & a_{1,1}a_{2,2}a_{3,3}a_{4,4} + a_{1,1}a_{2,3}a_{3,4}a_{4,2} + a_{1,1}a_{2,4}a_{3,2}a_{4,3} \\ & +a_{1,3}a_{2,2}a_{3,4}a_{4,1} + a_{1,4}a_{2,2}a_{3,1}a_{4,3} + a_{1,2}a_{2,4}a_{3,3}a_{4,1} \\ & +a_{1,4}a_{2,1}a_{3,3}a_{4,2} + a_{1,2}a_{2,3}a_{3,1}a_{4,4} + a_{1,3}a_{2,1}a_{3,2}a_{4,4} \\ & +a_{1,2}a_{2,1}a_{3,4}a_{4,3} + a_{1,3}a_{2,4}a_{3,1}a_{4,2} + a_{1,4}a_{2,3}a_{3,2}a_{4,1} \\ & -a_{1,1}a_{2,2}a_{3,4}a_{4,3} - a_{1,1}a_{2,4}a_{3,3}a_{4,2} - a_{1,1}a_{2,3}a_{3,2}a_{4,4} \\ & -a_{1,4}a_{2,2}a_{3,3}a_{4,1} - a_{1,3}a_{2,2}a_{3,1}a_{4,4} - a_{1,2}a_{2,1}a_{3,3}a_{4,4} \\ & -a_{1,2}a_{2,3}a_{3,4}a_{4,1} - a_{1,2}a_{2,4}a_{3,1}a_{4,3} - a_{1,3}a_{2,1}a_{3,4}a_{4,2} \\ & -a_{1,3}a_{2,4}a_{3,2}a_{4,1} - a_{1,4}a_{2,3}a_{3,1}a_{4,2} - a_{1,4}a_{2,1}a_{3,2}a_{4,3} \end{aligned}$$

(4.52) Definition:
Let $(R,+,\cdot)$ be a commutative ring and $1 \leq n \in \mathbb{N}$ a natural number. Let us now regard a map of the following form

$$D \;:\; \Big(R^n\Big)^n \to R \;:\; (a_1, a_2, \ldots, a_n) \mapsto D(a_1, a_2, \ldots, a_n)$$

We have already defined what it means that D is R-multi-linear: Namely iff for any $a_1, \ldots, a_n \in R^n$, any $x, y \in R^n$ any $b \in R$ and any $j \in 1 \ldots n$ we get

$$\begin{aligned} D(\ldots, a_{j-1}, x+y, a_{j+1}, \ldots) &= D(\ldots, a_{j-1}, x, a_{j+1}, \ldots) + D(\ldots, a_{j-1}, y, a_{j+1}, \ldots) \\ D(\ldots, a_{j-1}, ba_j, a_{j+1}, \ldots) &= bD(\ldots, a_{j-1}, a_j, a_{j+1}, \ldots) \end{aligned}$$

In this case D is said to be a **multi-linear form**, where *form* refers to fact that D maps to the base ring R. Now D is said to be **alternating** iff for any $a_1, \ldots, a_n \in R^n$ and any permutation $\sigma \in S_n$ we get

$$D(a_{\sigma(1)}, a_{\sigma(2)}, \ldots, a_{\sigma(n)}) \;=\; \operatorname{sgn}(\sigma) D(a_1, a_2, \ldots, a_n)$$

And finally D is said to be a **determinant form**, iff it is R-multi-linear and for any $a_1, \ldots, a_n \in R^n$ and any $i \neq j \in 1 \ldots n$ we get the implication

$$a_i \;=\; a_j \quad\Longrightarrow\quad D(a_1, a_2, \ldots, a_n) \;=\; 0$$

(4.53) Remark:

(i) As always we canonically identify the set $(R^n)^n$ of n n-tuples over R with the set of $(n \times n)$-matrices, by taking to the column-vectors of a matrix A. That is we consider $A = (a_1, a_2, \ldots, a_n)$ where the $a_i \in R^n$ are the column vectors of A

$$\begin{array}{rcl} \operatorname{mat}_n(R) & \longleftrightarrow & \Big(R^n\Big)^n \\ A & \mapsto & \Big(\operatorname{col}_1(A), \operatorname{col}_2(A), \ldots, \operatorname{col}_n(A)\Big) \\ \begin{pmatrix} \vdots & \vdots & & \vdots \\ a_1 & a_2 & \ldots & a_n \\ \vdots & \vdots & & \vdots \end{pmatrix} & \mapsfrom & (a_1, a_2, \ldots, a_n) \end{array}$$

In particular if D is a multi-linear form and A is a matrix of appropriate size, then $D(A) \in R$ is just D applied to the columns of A

$$D(A) \;=\; D\Big(\operatorname{col}_1(A), \operatorname{col}_2(A), \ldots, \operatorname{col}_n(A)\Big)$$

(ii) In the definition of the determinant (4.50) we used terms of the form $a_{1,\sigma(1)} a_{2,\sigma(2)} \ldots a_{n,\sigma(n)} \in R$. Note that letting $j := \sigma(i) \in 1 \ldots n$ the entry $a_{i,\sigma(i)}$ of A can also be addressed, as

$$a_{i,\sigma(i)} \;=\; a_{\sigma^{-1}(j),j}$$

Since R is commutative, the product runs over all $i \in 1 \dots n$ and σ is bijective, we can as well multiply over all $j = \sigma(i) \in 1 \dots n$, such that

$$\prod_{i=1}^{n} a_{i,\sigma(i)} \;=\; \prod_{j=1}^{n} a_{\sigma^{-1}(j),j}$$

Thus if the matrix $A = (a_{i,j})$ has the column vectors $a_j = \mathrm{col}_j(A) = (a_{1,j}, a_{2,j}, \dots, a_{n,j}) \in R^n$ then the determinant can be rewritten, as

$$\begin{aligned} \det(A) &= \det(a_1, a_2, \dots, a_n) \\ &= \sum_{\sigma \in S_n} \mathrm{sgn}(\sigma) \prod_{i=1}^{n} a_{i,\sigma(i)} \\ &= \sum_{\sigma \in S_n} \mathrm{sgn}(\sigma) \prod_{j=1}^{n} a_{\sigma^{-1}(j),j} \end{aligned}$$

That is $\det(a_1, a_2, \dots, a_n)$ selects the $\sigma^{-1}(j)$-th entry $a_{\sigma^{-1}(j),j}$ from the j-th vector a_j and sums up all these products. This may be a little awkward, but is ultimately due to the convention that in $A = (a_{i,j})$ the index i enumerates the row and j enumerates the column.

(iii) The online computer algebra system Wolfram α can also deal with vectors, matrices and compute determinants. Since this program is operated by command line, it stands to reason that it uses row-vectors. The input {x_1,x_2, x_3} is interpreted as the triple $x = (x_1, x_{2,3}) \in R^3$ for example. Likewise {{a_11,a_12, a_23}, {a_21, a_22, a_23}, {a_31, a_32, a_33}} denotes the matrix $A = (a_{ij}) \in \mathrm{mat}_3(R)$ whose row vectors are given to be $\mathrm{row}_i(A) = (a_{i1}, a_{i2}, a_{i3})$. Of course Wolfram α can handle higher (and lower) dimensions, as well.

(iv) If C and D are multi-linear forms and $a \in R$ is a scalars, then it is clear, that both aD and $C + D$ are a multi-linear forms, as well. That is the set of all multi-linear forms (of the same size) is an R-module under the point-wise operations

$$\begin{aligned} aD &: \mathrm{mat}_n(R) \to R \;:\; A \mapsto a \cdot D(A) \\ C + D &: \mathrm{mat}_n(R) \to R \;:\; A \mapsto C(A) + D(A) \end{aligned}$$

(v) If any $a_j \in R^n$ is given to be $a_j = (a_{1,j}, a_{2,j}, \dots, a_{n,j})$ and $\sigma \in S_n$ is any fixed permutation, then it is easy to check, that

$$D(a_1, a_2, \dots, a_n) \;:=\; a_{\sigma(1),1} a_{\sigma(2),2} \dots a_{\sigma(n),n}$$

is a multi-linear form. Therefore, if $r : S_n \to R$ is any map that assigns every permutation $\sigma \in S_n$ a scalar $r(\sigma) \in R$, then due to (iv) we obtain a multi-linear form, by letting

$$D(a_1, a_2, \dots, a_n) \;:=\; \sum_{\sigma \in S_n} r(\sigma)\, a_{\sigma(1),1} a_{\sigma(2),2} \dots a_{\sigma(n),n}$$

(4.54) Proposition: (viz. 851)
Let $(R, +, \cdot)$ be a commutative ring, $2 \leq n \in \mathbb{N}$ and $D : \mathrm{mat}_n(R) \to R$ be a multi-linear form over R. If now $2 = 1 + 1 \in \mathrm{NZD}(R)$ is a non-zero divisor of R, then the following three statements are equivalent:

(a) D is a determinant form: For any $a_1, \ldots, a_n \in R^n$ and any $i \neq j \in 1 \ldots n$ we get the implication

$$a_i \;=\; a_j \quad\Longrightarrow\quad D(a_1, a_2, \ldots, a_n) \;=\; 0$$

(b) D is alternating: For any $a_1, \ldots, a_n \in R^n$ and any permutation $\sigma \in S_n$ we get the equality of

$$D(a_{\sigma(1)}, a_{\sigma(2)}, \ldots, a_{\sigma(n)}) \;=\; \operatorname{sgn}(\sigma) D(a_1, a_2, \ldots, a_n)$$

(c) For any $a_1, \ldots, a_n \in R^n$ and any transposition $\tau \in S_n$ [that is $\tau = (i\,j)$ for some $i \neq j \in 1 \ldots n$] we get the following equality

$$D(a_{\tau(1)}, a_{\tau(2)}, \ldots, a_{\tau(n)}) \;=\; -D(a_1, a_2, \ldots, a_n)$$

Generally - for an arbitrary commutative ring - statement (a) is not equivalent, to (c), but (c) still implies $2D(a_1, a_2, \ldots, a_n) = 0$. Therefore in general we find

$$\text{(a)} \quad\Longrightarrow\quad \text{(b)} \quad\Longleftrightarrow\quad \text{(c)}$$

And if $D : \mathrm{mat}_n(R) \to R$ is a determinant form over some integral domain R, then for any n vectors a_1, $a_2, \ldots, a_n \in R^n$ we find the following implication

$$\{\, a_1, a_2, \ldots, a_n \,\} \text{ linearly dependent} \quad\Longrightarrow\quad D(a_1, a_2, \ldots, a_n) \;=\; 0$$

If $D : \mathrm{mat}_n(R) \to R$ is a determinant form over some non-zero, commutative ring $R \neq 0$ only, then for any n vectors a_1, $a_2, \ldots, a_n \in R^n$ we still find the implication

$$\operatorname{ann}\big(D(a_1, a_2, \ldots, a_n)\big) \;=\; 0 \quad\Longrightarrow\quad \{\, a_1, a_2, \ldots, a_n \,\} \text{ linearly independent}$$

(4.55) Lemma: (viz. 852)
Let $(R, +, \cdot)$ be a commutative ring, $1 \leq n \in \mathbb{N}$ and consider the determinant $\det : \mathrm{mat}_n(R) \to R$ defined in (4.50). Then this determinant satifies a couple of noteworthy properties:

(i) If $A \in \mathrm{mat}_n(R)$ is a matrix and A^* denotes the transpose of A, then both A and A^* share the same determinant, formally that is

$$\det(A^*) \;=\; \det(A)$$

(ii) The determinant is a homomorphism from the (non-commutative) monoid of matrices (under multiplication) to the (commutative) monoid of R under multiplication. I.e. for the identity matrix $\mathbb{1}_n \in \mathrm{mat}_n(R)$ and any two matrices $A, B \in \mathrm{mat}_n(R)$ we get

$$\begin{aligned} \det(\mathbb{1}_n) &= 1 \\ \det(AB) &= \det(A) \cdot \det(B) \end{aligned}$$

(iii) The determinant $\det : \mathrm{mat}_n(R) \to R$ is a determinant form, i.e. a multi-linear map, such that for

any matrix $A \in \mathrm{mat}_n(R)$ that has two identical columns the determinant is zero, i.e.

$$\exists\, i \neq j \in 1 \ldots n \;:\; \mathrm{col}_i(A) \;=\; \mathrm{col}_j(A) \quad\Longrightarrow\quad \det(A) \;=\; 0$$

(iv) If $D : \mathrm{mat}_n(R) \to R$ is any other determinant form on R, then D already is a multiple of the determinant. I.e. for any $A \in \mathrm{mat}_n(R)$ we get the following equality

$$D(A) \;=\; D(\mathbb{1}_n) \cdot \det(A)$$

(v) **Laplace expansion theorem**: Let $A \in \mathrm{mat}_n(R)$ be any square matrix over R and for any p, $q \in 1 \ldots n$ let us denote the matrix in which the p-th row and q-th column are scratched from A by $A_{p,q}$:

$$A_{p,q} \;=\; \begin{pmatrix} a_{1,1} & a_{1,2} & \ldots & a_{1,q-1} & a_{1,q+1} & \ldots & a_{1,n} \\ a_{2,1} & a_{2,2} & \ldots & a_{2,q-1} & a_{2,q+1} & \ldots & a_{2,n} \\ \vdots & \vdots & & \vdots & \vdots & & \vdots \\ a_{p-1,1} & a_{p-1,2} & \ldots & a_{p-1,q-1} & a_{p-1,q+1} & \ldots & a_{p-1,n} \\ a_{p+1,1} & a_{p+1,2} & \ldots & a_{p+1,q-1} & a_{p+1,q+1} & \ldots & a_{p+1,n} \\ \vdots & \vdots & & \vdots & \vdots & & \vdots \\ a_{n,1} & a_{n,2} & \ldots & a_{n,q-1} & a_{n,q+1} & \ldots & a_{n,n} \end{pmatrix}$$

More formally let us define the maps α and $\beta : 1 \ldots (n-1) \to 1 \ldots n$ by $\alpha(i) := i$ if $i < p$ and $\alpha(i) := i+1$ if $i \geq p$ respectively by $\beta(j) := j$ if $j < q$ and $\beta(i) := j+1$ if $j \geq q$. Then $A_{p,q}$ is the following matrix

$$A_{p,q} \;:=\; \Big(a_{\alpha(i),\beta(j)}\Big)_{i,j \in 1\ldots(n-1)} \;\in\; \mathrm{mat}_{n-1}(R)$$

Now fix any $p \in 1 \ldots n$, then we can evaluate the determinant of A by *expansion along the p-th row* of A, in the following sense

$$\det(A) \;=\; \sum_{q=1}^{n} (-1)^{p+q} a_{p,q} \det\big(A_{p,q}\big)$$

Likewise fix any $q \in 1 \ldots n$, then we can evaluate the determinant of A by *expansion along the q-th column* of A, in the following sense

$$\det(A) \;=\; \sum_{p=1}^{n} (-1)^{p+q} a_{p,q} \det\big(A_{p,q}\big)$$

(vi) Let $(S, +, \cdot)$ be another commutative ring and $\alpha : R \to S$ be a homomorphism of rings. For a matrix $A = (a_{i,j}) \in \mathrm{mat}_n(R)$ let us denote $\alpha(A) := (\alpha(a_{i,j})) \in \mathrm{mat}_n(S)$. Then the determinant of $\alpha(A)$ is

$$\det\big(\alpha(A)\big) \;=\; \alpha\big(\det(A)\big)$$

(4.56) Remark:
It is worth to note that the above lemma has some immediate consequences: Since the determinant is linear in every column of $A \in \mathrm{mat}_n(R)$ it is clear, that whenever a single column of A vanishes, so does the determinant:

$$\exists\, j \in 1 \ldots n \;:\; \mathrm{col}_j(A) = 0 \quad \Longrightarrow \quad \det(A) \;=\; 0$$

Of course this is also clear from the definition of det itself, as every product then contains at least one 0. Also if A contains a row, that is 0, then A^* contains a column, that is 0. But as A and A^* share the same determinant, we likewise find

$$\exists\, i \in 1 \ldots n \;:\; \mathrm{row}_i(A) = 0 \quad \Longrightarrow \quad \det(A) \;=\; 0$$

Again, this is also clear from the explicit formula of the determinant. Furthermore since det is a determinant form, (4.54) tells us, that det also is alternating. That is, permuting the columns of A just changes the sign of the determinant

$$\det \begin{pmatrix} | & & | \\ a_{\sigma(1)} & \cdots & a_{\sigma(n)} \\ | & & | \end{pmatrix} \;=\; \mathrm{sgn}(\sigma) \cdot \det \begin{pmatrix} | & & | \\ a_1 & \cdots & a_n \\ | & & | \end{pmatrix}$$

Likewise transposing A permuting the columns of A^* and transposing again, is just the same as permuting the rows of A. But since transposing does not change the determinant, we also see that

$$\det \begin{pmatrix} — & a_{\sigma(1)} & — \\ & \vdots & \\ — & a_{\sigma(n)} & — \end{pmatrix} \;=\; \mathrm{sgn}(\sigma) \cdot \det \begin{pmatrix} — & a_1 & — \\ & \vdots & \\ — & a_n & — \end{pmatrix}$$

(4.57) Example:
The easiest application of the Laplace expansion theorem is the case $n = 2$. That is we want to compute the determinant of the general (2×2)-matrix

$$A \;=\; \begin{pmatrix} a_{1,1} & a_{1,2} \\ a_{2,1} & a_{2,2} \end{pmatrix}$$

We choose $p = 1$ that is we will expand the determinant along the first row of A. As for an $a \in R$ we trivially have $\det(a) = a$ this quickly yields the same formula we encountered in the example before

$$\det \begin{pmatrix} a_{1,1} & a_{1,2} \\ a_{2,1} & a_{2,2} \end{pmatrix} \;=\; a_{1,1}\det(a_{2,2}) - a_{1,2}\det(a_{2,1}) \;=\; a_{1,1}a_{2,2} - a_{1,2}a_{2,1}$$

More instructive is the case $n = 3$, that is we want to compute the determinant of the general (3×3)-matrix

$$A \;=\; \begin{pmatrix} a_{1,1} & a_{1,2} & a_{1,3} \\ a_{2,1} & a_{2,2} & a_{2,3} \\ a_{3,1} & a_{3,2} & a_{3,3} \end{pmatrix}$$

Let us choose $q = 2$, that is we will expand the determinant along the middle column of A - there is no

special reason for this choice, apart from emphasizing that it can be done. Then the Laplace expansion theorem yields

$$\det\begin{pmatrix} a_{1,1} & a_{1,2} & a_{1,3} \\ a_{2,1} & a_{2,2} & a_{2,3} \\ a_{3,1} & a_{3,2} & a_{3,3} \end{pmatrix} = -a_{1,2}\det\begin{pmatrix} a_{2,1} & a_{2,3} \\ a_{3,1} & a_{3,3} \end{pmatrix} + a_{2,2}\det\begin{pmatrix} a_{1,1} & a_{1,3} \\ a_{3,1} & a_{3,3} \end{pmatrix} - a_{3,2}\det\begin{pmatrix} a_{1,1} & a_{1,3} \\ a_{2,1} & a_{2,3} \end{pmatrix}$$

And using the formula for the determinants of those (2×2)-matrices we wind up with precisely the same formula, we found while looking at permutations

$$\begin{aligned} \det\begin{pmatrix} a_{1,1} & a_{1,2} & a_{1,3} \\ a_{2,1} & a_{2,2} & a_{2,3} \\ a_{3,1} & a_{3,2} & a_{3,3} \end{pmatrix} &= -a_{1,2}\left(a_{2,1}a_{3,3} - a_{2,3}a_{3,1}\right) \\ &\quad +a_{2,2}\left(a_{1,1}a_{3,3} - a_{1,3}a_{3,1}\right) \\ &\quad -a_{3,2}\left(a_{1,1}a_{2,3} - a_{1,3}a_{2,1}\right) \\ &= -a_{1,2}a_{2,1}a_{3,3} - a_{1,3}a_{2,2}a_{3,1} - a_{1,1}a_{2,3}a_{3,2} \\ &\quad +a_{1,2}a_{2,3}a_{3,1} + a_{1,1}a_{2,2}a_{3,3} + a_{1,3}a_{2,1}a_{3,2} \end{aligned}$$

The Laplace expansion theorem yields an algorithm to compute the determinant of any square matrix by recursion. Though this is a vast progress compared to the definition, it can result in an excessively long computation, that we would like to evade, still. However there are two major cases in which the computation of the determinant is easily feasible:

(4.58) Proposition: (viz. 858)
Let $(R, +, \cdot)$ be a commutative ring $1 \leq m$, $n \in \mathbb{N}$ and $A \in \mathrm{mat}_m(R)$ and B, $T = (t_{i,j}) \in \mathrm{mat}_n(R)$ be square matrices over R. Then we get

(i) Let also $C \in \mathrm{mat}_{m,n}(R)$ and $0 \in \mathrm{mat}_{n,m}$, then we can compute the trace and determinant of the following block matrix, using

$$\begin{aligned} \mathrm{tr}\begin{pmatrix} A & C \\ 0 & B \end{pmatrix} &= \mathrm{tr}(A) + \mathrm{tr}(B) \\ \det\begin{pmatrix} A & C \\ 0 & B \end{pmatrix} &= \det(A) \cdot \det(B) \end{aligned}$$

(ii) In particular the trace and determinant of a direct sum $A \oplus B$ of matrices can be computed for A and B separately, using

$$\begin{aligned} \mathrm{tr}(A \oplus B) &= \mathrm{tr}(A) + \mathrm{tr}(B) \\ \det(A \oplus B) &= \det(A) \cdot \det(B) \end{aligned}$$

(iii) If T is an lower triangular (i.e. $i < j \implies t_{i,j} = 0$) matrix or an upper triangular matrix (i.e. $i > j \implies t_{i,j} = 0$), then the determinant of T is just the product of its diagonal elements

$$\det(T) = \prod_{i=1}^{n} t_{i,i}$$

(4.59) Remark:
It generally is a reasonable strategy to use the Gaussian algorithm to bring a matrix $A \in \mathrm{mat}_n(R)$ into upper triangular form. The determinant of this matrix can then be computed using (ii). However the Gaussian algorithm makes use of elementary matrices, so we have to keep track how the determinant changes: If $\sigma \in S_n$ is any permutation, $a \in R$ is a scalar and $i \neq j \in 1 \ldots n$, then due to the multiplicativity of the determinant we get

$$\begin{aligned} \det\Big(P_\sigma A\Big) &= \mathrm{sgn}(\sigma)\det(A) \\ \det\Big(D_i(a)A\Big) &= a \cdot \det(A) \\ \det\Big(T_{i,j}(a)A\Big) &= \det(A) \end{aligned}$$

Let us regard an example of this method: Say we would like to compute the determinant of the following (3×3)-matrix over $\mathbb{Z}$.

$$A = \begin{pmatrix} 2 & 6 & 2 \\ 0 & 2 & 2 \\ 3 & 7 & 4 \end{pmatrix}$$

We aim to get A into upper triangular form. In order to get there we divide the first row by 2 and interchange the second and third rows, arriving at

$$A_1 = \begin{pmatrix} 1 & 3 & 1 \\ 3 & 7 & 4 \\ 0 & 2 & 2 \end{pmatrix}$$

Due to our operations we know, that $\det(A_1) = -1/2 \cdot \det(A)$. Next we subtract 3-times the first row from the second row, now getting to

$$A_2 = \begin{pmatrix} 1 & 3 & 1 \\ 0 & -2 & 1 \\ 0 & 2 & 2 \end{pmatrix}$$

Note that this did not change the determinant at all: $\det(A_2) = \det(A_1)$. Adding the the second row to the third row we arrive at the upper triangular form already

$$T = \begin{pmatrix} 1 & 3 & 1 \\ 0 & -2 & 1 \\ 0 & 0 & 3 \end{pmatrix}$$

Again this did not change the determinant $\det(T) = \det(A_2)$. Since T is triangular it is easy to compute it's determinant. And retracing our steps we thereby find the determinant of A

$$-6 = \det(T) = \det(A_2) = \det(A_1) = -\frac{1}{2}\det(A)$$

$$\Longrightarrow \quad \det(A) = (-2) \cdot (-6) = 12$$

Clearly the advantage of this method lies in the fact that it takes n steps to get A into upper triangular form. And from there the determinant is nothing but the product of the diagonal elements. Using the Laplace expansion theorem (for all its worth) requires to expand $n!$ times.

(4.60) Remark:
There is an easy way to prove statement (ii) in (4.58): Simply define the map $D : \mathrm{mat}_m(R) \to R$ by $D(A) := \det(A \oplus B)$. As det is linear in every argument, so is D. Also it is clear that D inherits being a determinant form from det. Finally it is not hard to see, that

$$D(\mathbb{1}_m) \;=\; \det(\mathbb{1}_m \oplus B) \;=\; \det(B)$$

Hence we may invoke (4.55.(iv)) to find that for any $A \in \mathrm{mat}_m(R)$ we have

$$\det(A \oplus B) \;=\; D(A) \;=\; \det(A) \cdot D(\mathbb{1}_m) \;=\; \det(A) \cdot \det(B)$$

However we chose to present a direct proof of this statement, in order to have more independence between proofs and as it is a natural reflex to split S_{m+n} into S_m and S_n when looking at the construction of $A \oplus B$.

In the expansion theorem of Laplace (4.55.(v)) we encountered the sub-matrices $A_{p,q}$ in which the p-th row and q-th column of A have been deleted. Even though these seem to be just a peculiarity of the expansion theorem, these can also be applied to solving systems of linear equations. In order to formulate Cramer's rule (which is a solution formula) we need to introduce some notation first:

(4.61) Definition:
Let $(R, +, \cdot)$ be a commutative ring and $2 \leq n \in \mathbb{N}$, if now $A = (a_{i,j})$ is a square matrix of size $(n \times n)$ and $p, q \in 1 \ldots n$ are some indexes we denote (as in the expansion theorem of Laplace) again

$$A_{p,q} \;=\; \begin{pmatrix} a_{1,1} & a_{1,2} & \ldots & a_{1,q-1} & a_{1,q+1} & \ldots & a_{1,n} \\ a_{2,1} & a_{2,2} & \ldots & a_{2,q-1} & a_{2,q+1} & \ldots & a_{2,n} \\ \vdots & \vdots & & \vdots & \vdots & & \vdots \\ a_{p-1,1} & a_{p-1,2} & \ldots & a_{p-1,q-1} & a_{p-1,q+1} & \ldots & a_{p-1,n} \\ a_{p+1,1} & a_{p+1,2} & \ldots & a_{p+1,q-1} & a_{p+1,q+1} & \ldots & a_{p+1,n} \\ \vdots & \vdots & & \vdots & \vdots & & \vdots \\ a_{n,1} & a_{n,2} & \ldots & a_{n,q-1} & a_{n,q+1} & \ldots & a_{n,n} \end{pmatrix}$$

the matrix A in which the p-th row and q-th column have been scratched. Formall we define the maps α and $\beta : 1 \ldots (n-1) \to 1 \ldots n$ by $\alpha(i) := i$ if $i < p$ and $\alpha(i) := i + 1$ if $i \geq p$ respectively by $\beta(j) := j$ if $j < q$ and $\beta(i) := j + 1$ if $j \geq q$. Then $A_{p,q}$ is the following matrix

$$A_{p,q} \;:=\; \left(a_{\alpha(i),\beta(j)}\right)_{i,j \in 1\ldots(n-1)} \;\in\; \mathrm{mat}_{n-1}(R)$$

Now the **cofactor matrix** $\mathrm{cof}(A)$ is defined to be the $(n \times n)$-matrix whose coefficients are (up to sign) the determinant of these $A_{p,q}$. The transpose of the cofactor matrix is said to be the **adjugate matrix** $A^{\#}$ of A. We also define these notions formally:

$$\begin{aligned} \mathrm{cof}(A) &:= \Big((-1)^{p+q} \det(A_{p,q}) \Big)_{p,q \in 1 \ldots n} \\ A^{\#} &:= \Big(\mathrm{cof}(A) \Big)^{*} \end{aligned}$$

(4.62) Example:
In case $n = 2$ the $A_{p,q}$ are particularly simple, since $A_{1,1} = a_{2,2}$ $A_{1,2} = a_{2,1}$ $A_{2,1} = a_{1,2}$ and $A_{2,2} = a_{1,1}$. Hence the cofactor matrix $\mathrm{cof}(A) = (c_{i,j})$ has the coefficients $c_{1,1} = a_{2,2}$ $c_{1,2} = -a_{2,1}$ $c_{2,1} = -a_{1,2}$ and $c_{2,2} = a_{1,1}$. To get the adjugate matrix of A all we have to do is transposing:

$$\begin{pmatrix} a_{1,1} & a_{1,2} \\ a_{2,1} & a_{2,2} \end{pmatrix}^{\#} = \begin{pmatrix} a_{2,2} & -a_{1,2} \\ -a_{2,1} & a_{1,1} \end{pmatrix}$$

The next step $n = 3$ already requires some accountant's work. We will just present the result only, the reader is asked to fill in the details, as needed

$$\begin{pmatrix} a_{1,1} & a_{1,2} & a_{1,3} \\ a_{2,1} & a_{2,2} & a_{2,3} \\ a_{3,1} & a_{3,2} & a_{3,3} \end{pmatrix}^{\#} = \begin{pmatrix} a_{2,2}a_{3,3} - a_{2,3}a_{3,2} & a_{1,3}a_{3,2} - a_{1,2}a_{3,3} & a_{1,2}a_{2,3} - a_{1,3}a_{2,2} \\ a_{2,3}a_{3,1} - a_{2,1}a_{3,3} & a_{1,1}a_{3,3} - a_{1,3}a_{3,1} & a_{1,3}a_{2,1} - a_{1,1}a_{2,3} \\ a_{2,1}a_{3,2} - a_{2,2}a_{3,1} & a_{1,2}a_{3,1} - a_{1,1}a_{3,2} & a_{1,1}a_{2,2} - a_{1,2}a_{2,1} \end{pmatrix}$$

(4.63) Theorem: (viz. 860) **Cramer's Rule:**
Let $(R, +, \cdot)$ be any commutative ring $2 \leq n \in \mathbb{N}$ and $A \in \mathrm{mat}_n(R)$ be a $(n \times n)$-matrix over R. Then the following statements hold true

(i) For $j \in 1 \ldots n$ let us denote $a_j := \mathrm{col}_j(A)$ the j-th column-vector of A. If now $b \in R^n$ is another vector and $x = (x_1, x_2, \ldots, x_n) \in R^n$ is a solution of the SLE $Ax = b$, then for any $j \in 1 \ldots n$ the x_j satisfy the following identity

$$\det(A) x_j = \det \begin{pmatrix} | & & | & | & | & & | \\ a_1 & \cdots & a_{j-1} & b & a_{j+1} & \cdots & a_n \\ | & & | & | & | & & | \end{pmatrix}$$

(ii) The matrix A is invertible if and only if its determinant is a unit of R. And in this case the determinant of the inverse matrix is the multiplicative inverse of the determinant, that is

$$\det(A^{-1}) = \det(A)^{-1}$$

(iii) For any $A \in \mathrm{mat}_n(R)$ the adjugate matrix $A^{\#}$ of A is the same as the inverse matrix A^{-1} of A, up to the determinant $\det(A)$, as a factor. That is $A^{\#}$ satisfies the equalities below. And if $\det(A)$ (and hence A itself) is invertible we can reformulate them to get A^{-1}

$$A^{\#} A = A A^{\#} = \det(A)\, \mathbb{1}_n$$

$$A^{-1} \;=\; \det(A)^{-1}A^{\#}$$

(iv) The adjugate matrix of the transpose matrix A^* simply is the transpose of the adjugate matrix of A

$$(A^{\#})^* \;=\; (A^*)^{\#}$$

(v) If A is invertible, then so is the adjugate matrix $A^{\#}$ of A. And in this case we also give the inverse and the determinant of $A^{\#}$ to be the following

$$\begin{aligned}\left(A^{\#}\right)^{-1} &= \left(A^{-1}\right)^{\#}\\ \det\left(A^{\#}\right) &= \det(A)^{n-1}\end{aligned}$$

(4.64) Remark:
In commutative rings R, where transposition in the rule $(ab)^{-1} = b^{-1}a^{-1}$ has no impact, it is commonplace to denote the inverse of $a \in R$ by

$$\frac{1}{a} \;=\; a^{-1}$$

We usually try to avoid this, as we reserved this notation for localizations. However in this case it is worthwhile to rewrite the above equations in this notation, as it may be a little less confusing to have only one power -1. That is if $A \in \mathrm{mat}_n(R)$ is an invertible matrix, then we get

$$\begin{aligned}\det(A^{-1}) &= \frac{1}{\det(A)}\\ A^{-1} &= \frac{1}{\det(A)}A^{\#}\end{aligned}$$

(4.65) Corollary: (viz. 863)
Let $(R,+,\cdot)$ be a commutative ring, $1 \leq n \in \mathbb{N}$ and consider a square matrix $A \in \mathrm{mat}_n(R)$. Let us denote the rows of A by $r_i := \mathrm{row}_i(A)$ and the columns respectively by $c_j := \mathrm{col}_j(A)$. That is

$$A \;=\; \begin{pmatrix} \text{—} & r_1 & \text{—} \\ & \vdots & \\ \text{—} & r_n & \text{—} \end{pmatrix} \;=\; \begin{pmatrix} | & & | \\ c_1 & \cdots & c_n \\ | & & | \end{pmatrix}$$

(i) Then for any commutative ring R the following 6 statements are equivalent

(a) $\det(A) \in R^*$

(b) A is invertible

(c) $\exists\, B \in \mathrm{mat}_n(R) \;:\; AB = \mathbb{1}_n$

(d) $\exists\, B \in \mathrm{mat}_n(R) \;:\; BA = \mathbb{1}_n$

(e) $\{\, c_1, c_2, \ldots, c_n \,\}$ is a basis of R^n

(f) $\{\, r_1, r_2, \ldots, r_n \,\}$ is a basis of R^n

(ii) And for an integral domain R also the following 4 statements are equivalent

(a) $\det(A) = 0$

(b) $\mathrm{kn}(A) \neq 0$

(c) $\{ c_1, c_2, \ldots, c_n \} \subseteq R^n$ is linearly dependent

(d) $\{ r_1, r_2, \ldots, r_n \} \subseteq R^n$ is linearly dependent

(4.66) Corollary: (viz. 864) **Cramer's Rule**
Let $(R, +, \cdot)$ be any commutative ring $2 \leq n \in \mathbb{N}$ and $A = (a_{i,j}) \in \mathrm{mat}_n(R)$ be a square $(n \times n)$-matrix over R. Also let M be an R-module containing the elements $x_i \in M$ and $y_i \in M$ (where $i \in 1 \ldots n$). Finally suppose the following equations hold true

$$\begin{array}{ccccccc} a_{1,1}x_1 & + & a_{1,2}x_2 & + \cdots + & a_{1,n}x_n & = & y_1 \\ a_{2,1}x_1 & + & a_{2,2}x_2 & + \cdots + & a_{2,n}x_n & = & y_2 \\ \vdots & & \vdots & & \vdots & & \vdots \\ a_{n,1}x_1 & + & a_{n,2}x_2 & + \cdots + & a_{n,n}x_n & = & y_n \end{array}$$

Then we may compute the solution $(x_1, x_2, \ldots, x_n) \in M^n$ to the above system of linear equations in much the same way that holds true in case $M = R$. That is: For any $j \in 1 \ldots n$ we get

$$\det(A)x_j \;=\; \sum_{i=1}^{n} (-1)^{i+j} \det(A_{i,j})\, y_i$$

If A is invertible, then this is a solution formula for the x_j. And generally we thereby find the following inclusion of sub-modules of M

$$\det(A) \cdot \mathrm{Lh}\{ x_1, x_2, \ldots, x_n \} \quad \subseteq \quad \mathrm{Lh}\{ y_1, y_2, \ldots, y_n \}$$

There is a generalization to the Laplace expansion theorem that deals with determinants of whole sub-matrices of A. In the next section these determinants of sub-matrices will be called *minors* and these will play an important role for the rank of a matrix and in the theory of canonical forms. For completeness purposes we present this generalization, as well.

(4.67) Definition:
Let $1 \leq n$, $r \in \mathbb{N}$ such that $r \leq n$, then we define the set of *ascending chains of indexes* of length r by

$$\mathrm{Asc}(r, n) \;:=\; \{ \alpha : 1 \ldots r \to 1 \ldots n \mid \alpha(1) < \alpha(2) < \cdots < \alpha(r) \}$$

And if $\alpha \in \mathrm{Asc}(r, n)$ is such a chain of indexes, then we define its **scope** $S(\alpha)$ to be the set of indices that comprise α, respectively its **absolute value** $|\alpha|$ to be the sum of these indices, that is

$$\begin{aligned} S(\alpha) &:= \{ \alpha(i) \mid i \in 1 \ldots r \} \\ |\alpha| &:= \sum_{i=1}^{r} \alpha(i) \end{aligned}$$

And if $r < n$ then we also define the *complementary chain of indexes* $\widehat{\alpha} \in \mathrm{Asc}(n-r,n)$ of α to be the chain of length $n-r$ that contains exactly these numbers, that α left out. That is $\widehat{\alpha}$ is the uniquely determined ascending chain of indexes that satisfies

$$S(\widehat{\alpha}) \;=\; (1\ldots n) \setminus S(\alpha)$$

Let $(R,+,\cdot)$ be a commutative ring, $1 \leq m, n \in \mathbb{N}$ and $A \in \mathrm{mat}_{m,n}(R)$ be a matrix of any size over R. If now $1 \leq r, s \in \mathbb{N}$ and we fix the maps $\alpha : 1\ldots r \to 1\ldots m$ and $\beta : 1\ldots s \to 1\ldots n$ then we define the **sub-matrix** $A[\alpha \mid \beta]$ of A to be the following $(r \times s)$-matrix

$$A[\alpha \mid \beta] \;:=\; \begin{pmatrix} a_{\alpha(1),\beta(1)} & a_{\alpha(1),\beta(2)} & \cdots & a_{\alpha(1),\beta(s)} \\ a_{\alpha(2),\beta(1)} & a_{\alpha(2),\beta(2)} & \cdots & a_{\alpha(2),\beta(s)} \\ \vdots & \vdots & & \vdots \\ a_{\alpha(r),\beta(1)} & a_{\alpha(r),\beta(2)} & \cdots & a_{\alpha(r),\beta(s)} \end{pmatrix} \;\in\; \mathrm{mat}_{r,s}(R)$$

(4.68) Example:
We usually write out the chain of indexes $\alpha \in \mathrm{Asc}(r,n)$ as an r-tuple $(\alpha(1),\alpha(2),\ldots,\alpha(r)) \in (1\ldots n)^r$. In this notation it is clear that $\mathrm{Asc}(3,4)$ is the following set - as for any $\alpha \in \mathrm{Asc}(3,4)$ the only choice is which index to omit:

$$\mathrm{Asc}(3,4) \;=\; \{\,(1,2,3),\,(1,2,4),\,(1,3,4),\,(2,3,4)\,\}$$

Generally $\alpha \in \mathrm{Asc}(r,n)$ is uniquely determined by its scope, as we require the indices to be in ascending order. Therefore the number of elements of $\mathrm{Asc}(r,n)$ is precisely the number of subsets of $1\ldots n$ that contain r elements. This is one of the basic problems of combinatorics and the answer is

$$\#\mathrm{Asc}(r,n) \;=\; \binom{n}{r}$$

Let us also present an example of a complementary chain of indexes: If we take $\alpha = (2,5) \in \mathrm{Asc}(2,5)$ then the scope of α is $S(\alpha) = \{\,2,5\,\}$ and thereby $S(\widehat{\alpha}) = \{\,1,3,4\,\}$. That is $\widehat{\alpha} \in \mathrm{Asc}(3,5)$ has to be the chain $\widehat{\alpha} = (1,3,4)$ of indexes.

(4.69) Remark:
In the Laplace expansion theorem we used the sub-matrices $A_{p,q}$ of A. In the light of the above definition we can rewrite this as

$$A_{p,q} \;=\; A[\widehat{p} \mid \widehat{q}]$$

Thereby $\widehat{p}$ is the complementary chain of indexes of p in $1\ldots m$ and $\widehat{q}$ is the complementary chain of indexes of q in $1\ldots n$. That is $\widehat{p}$ and $\widehat{q}$ are the following maps: $\widehat{p} : 1\ldots(m-1) \to 1\ldots m$ is defined by $\widehat{p}(i) = i$ for $i < p$ and $\widehat{p}(i) = i+1$ for $i \geq p$. And likewise $\widehat{q} : 1\ldots(n-1) \to 1\ldots n$ is given to be $\widehat{q}(j) = j$ for $j < q$ and $\widehat{q}(j) = j+1$ for $j \geq q$.

(4.70) Proposition: (viz. 911)

(i) *Laplace expansion theorem:* Let $(R, +, \cdot)$ be a commutative ring and $A \in \mathrm{mat}_n(R)$ a square matrix over R. If we now fix any $r \in 1 \dots n$ and any α resp. $\beta \in \mathrm{Asc}(r, n)$, then we find

$$\begin{aligned} \det(A) &= \sum_{\beta \in \mathrm{Asc}(r,n)} (-1)^{|\alpha|+|\beta|} \det\big(A[\alpha \mid \beta]\big) \det\big(A[\widehat{\alpha} \mid \widehat{\beta}]\big) \\ &= \sum_{\alpha \in \mathrm{Asc}(r,n)} (-1)^{|\alpha|+|\beta|} \det\big(A[\alpha \mid \beta]\big) \det\big(A[\widehat{\alpha} \mid \widehat{\beta}]\big) \end{aligned}$$

(ii) *Cauchy-Binet formula:* If $(R, +, \cdot)$ is a commutative ring and A and B are matrices $A \in \mathrm{mat}_{k,m}(R)$ and $B \in \mathrm{mat}_{m,n}(R)$ such that $C := AB$ is in $C \in \mathrm{mat}_{k,n}(R)$. Then for any $r \in \mathbb{N}$ with $1 \leq r \leq \min\{ k, m, n \}$ and any $\alpha \in \mathrm{Asc}(r, k)$, $\gamma \in \mathrm{Asc}(r, n)$ we get

$$\det\big(C[\alpha \mid \gamma]\big) = \sum_{\beta \in \mathrm{Asc}(r,m)} \det\big(A[\alpha \mid \beta]\big) \det\big(B[\beta \mid \gamma]\big)$$

These formulas are truly elegant: (i) obviously is a generalization of the Laplace expansion theorem in (4.55.(v)) and (ii) generalizes the multiplicative property $\det(AB) = \det(A) \cdot \det(B)$. At the same time the Cauchy-Binet formula is astoundingly similar to the multiplication of matrices. The proofs are a different story, however: Both are technical colossi with little content from the department of insight. If you really need to look at these, you have been warned...

4.6 Rank of Matrices

In section 3.10 we have introduced the rank of a module M to be the minimal number of elements that are required to generate M. And we also found that we have to distinguish between this rank and the linear freedom, that is the maximal number of linear independent elements inside M. As the difference between these two invariants comes from torsion, they are equal when it comes to vector-spaces (i.e. when the base ring of M is a field).
For a matrix A there are even 5 different ways one can think of, when defining the rank of A. And sadly things can get rather complicated, in general. However it will turn out that that in case of an integral domain R four of these notions will have the same result. And when R is a PID (in particular for a field), all five will agree.

(4.71) Definition:
Let $(R,+,\cdot)$ be an arbitrary ring, $1 \leq m$, $n \in \mathbb{N}$ and consider a matrix $A = (a_{i,j}) \in \mathrm{mat}_{m,n}(R)$ of any size over R. Then the image of A is a sub-module $\mathrm{im}(A) \leq_{\mathsf{m}} R^m$. Thereby we define the **image-rank** of A to be the rank of the image of A, as a sub-module of R^m:

$$\text{i-rank}(A) \;:=\; \mathrm{rank}\big(\mathrm{im}(A)\big)$$

To introduce the next two notions of a rank of A we need to take a closer look at A: Let us denote the rows of A be $r_i := \mathrm{row}_i(A)$ and the columns of A by $c_j := \mathrm{col}_j(A)$, that is

$$A \;=\; \begin{pmatrix} \text{—} & r_1 & \text{—} \\ \text{—} & r_2 & \text{—} \\ & \vdots & \\ \text{—} & r_m & \text{—} \end{pmatrix} \;=\; \begin{pmatrix} | & | & & | \\ c_1 & c_2 & \dots & c_n \\ | & | & & | \end{pmatrix}$$

Then for any subset $I \subseteq 1 \dots m$ resp. any $J \subseteq 1 \dots n$ let us abbreviate the sets of rows of A with indices $i \in I$ by r_I resp. the set of columns of A with indices $j \in J$ by c_J, formally

$$\begin{aligned} r_I \;&:=\; \{\, r_i \mid i \in I \,\} \;\subseteq\; R^n \\ c_J \;&:=\; \{\, c_j \mid j \in J \,\} \;\subseteq\; R^m \end{aligned}$$

Then we define the **row-rank** (respectively the **column-rank**) of A to be the maximal number of rows (respectively columns) of A that are R-linearly independent. Formally that is

$$\begin{aligned} \text{r-rank}(A) \;&:=\; \max\left\{ \#I \;\middle|\; \begin{array}{l} I \subseteq 1 \dots m, \text{ such that} \\ r_I \text{ is } R\text{-lin. independent} \end{array} \right\} \\ \text{c-rank}(A) \;&:=\; \max\left\{ \#J \;\middle|\; \begin{array}{l} J \subseteq 1 \dots n, \text{ such that} \\ c_J \text{ is } R\text{-lin. independent} \end{array} \right\} \end{aligned}$$

(4.72) Proposition: (viz. 917)
We continue with the notation of the definition above. In the following definition M is sometimes called the *column-space* of A and N is called the *row-space* of A

$$\begin{aligned} M &:= \mathrm{Lh}\{\, c_j \mid j \in 1 \ldots m \,\} = \mathrm{im}(A) \leq_{\mathfrak{m}} R^m \\ N &:= \mathrm{Lh}\{\, r_i \mid i \in 1 \ldots n \,\} = \mathrm{im}(A^*) \leq_{\mathfrak{m}} R^n \end{aligned}$$

(i) Let $R \neq 0$ be a non-zero, commutative ring and consider any matrix $A \in \mathrm{mat}_{m,n}(R)$ over R. Then we find the following inequalities

$$\begin{aligned} \text{c-rank}(A) &\leq \text{i-rank}(A) \\ \text{c-rank}(A) &\leq \min\{\, m, n \,\} \\ \text{r-rank}(A) &\leq \min\{\, m, n \,\} \end{aligned}$$

(ii) Let $R \neq 0$ be a non-zero, commutative ring and consider two matrices $A \in \mathrm{mat}_{l,m}(R)$ and $B \in \mathrm{mat}_{m,n}(R)$ such that $AB \in \mathrm{mat}_{l,n}(R)$. Then

$$\begin{aligned} \text{c-rank}(AB) &\leq \text{c-rank}(B) \\ \text{r-rank}(AB) &\leq \text{r-rank}(A) \end{aligned}$$

In particular: If R is an integral domain, we will see in (vi) that the column- and row-ranks of A agree $\mathrm{rank}(A) := \text{c-rank}(A) = \text{r-rank}(A)$ and hence in this case we have

$$\mathrm{rank}(AB) \leq \min\{\, \mathrm{rank}(A), \mathrm{rank}(B) \,\}$$

(iii) If $1 \leq r, s \in \mathbb{N}$, $\alpha \in \mathrm{Asc}(r,m)$ and $\beta \in \mathrm{Asc}(s,n)$, then the rank of the submatrix $A[\alpha \mid \beta]$ cannot exceed the rank of A

$$\begin{aligned} \text{c-rank}(A[\alpha \mid \beta]) &\leq \text{c-rank}(A) \\ \text{r-rank}(A[\alpha \mid \beta]) &\leq \text{r-rank}(A) \end{aligned}$$

(iv) If R is an integral domain and $S \in \mathrm{mat}_m(R)$ and $T \in \mathrm{mat}_n(R)$ are square matrices with $\det(S) \neq 0$ and $\det(T) \neq 0$, then

$$\begin{aligned} \text{c-rank}(SAT) &= \text{c-rank}(A) \\ \text{r-rank}(SAT) &= \text{r-rank}(A) \end{aligned}$$

(v) If R is an integral domain and and A is in *echelon form* [recall, this means $A = 0$ or there is some $1 \leq r \in \mathbb{N}$ and some $\mu \in \mathrm{Asc}(r,n)$ such that for any $i \in 1 \ldots r$ we have $a_{i,\mu(i)} \neq 0$ but for $j < \mu(i)$ we also have $a_{i,j} = 0$. Finally $r_k = 0$ for any $k \in (r+1) \ldots m$]. Then the number of non-zero rows of A already is the column- and the row-rank of A

$$\text{c-rank}(A) = \text{r-rank}(A) = r$$

(vi) If R is an integral domain, then the column-rank of A is just the linear freedom of the image of A and hence does not exceed the image rank of A. Also the row-rank of A is just the linear freedom of N and agrees with the column-rank of A. That is

$$\begin{aligned} \text{c-rank}(A) &= \text{free}\big(M\big) \leq \text{i-rank}(A) \\ \text{r-rank}(A) &= \text{free}\big(N\big) = \text{c-rank}(A) \end{aligned}$$

(vii) If R is a PID (in particular an integral domain), then the rank of the image $\text{im}(A)$ equals the column-rank of A and hence we have the following (in)equalties

$$\text{c-rank}(A) = \text{r-rank}(A) = \text{i-rank}(A) \leq \min\{\, m, n \,\}$$

(viii) If R is a skew-field, then the row-rank of A is precisely the dimension of N (as a vector-space). Likewise the column-rank of A is the dimension of M and both agree. These are the equalities of

$$\text{i-rank}(A) = \text{c-rank}(A) = \dim(M) = \dim(N) = \text{r-rank}(A)$$

(ix) Let R be an integral domain again and $x_1, x_2, \ldots, x_m \in R^n$ be n-tuples where $1 \leq m \leq n \in \mathbb{N}$ where $1 \leq m \leq n \in \mathbb{N}$. For $\alpha \in \text{Asc}(m,n)$ let us also denote the projection $P_\alpha : R^n \to R^m$ that is defined by $P_\alpha(a_1, \ldots, a_n) = (a_{\alpha(1)}, \ldots, a_{\alpha(m)})$. Then we find the following equivalence [for a general commutative ring R we still have (b) $\implies$ (a)]

(a) $\{\, x_1, \ldots, x_m \,\} \subseteq R^n$ is linearly independent

(b) There is some $\alpha \in \text{Asc}(m,n)$ such that the set of projected n-tuples $\{\, P_\alpha(x_1), \ldots, P_\alpha(x_m) \,\} \subseteq R^m$ is linearly independent.

(4.73) Remark:
The tricky part in this proof is to show that the row-rank matches the column rank $\text{c-rank}(A) = \text{r-rank}(A)$. Most textbooks derive this result from (iv) and (v): If we had (iv) and (v) then we could use Gaussian elimination (4.29) to find some matrix $S \in \text{mat}_n(R)$ such that SA is in echelon form. Thereby S can be taken to be a product of elementary matrices. And as any elementary matrix has non-zero determinant, so does S. Then we see

$$\text{c-rank}(A) = \text{c-rank}(SA) = \text{r-rank}(SA) = \text{r-rank}(A)$$

We will derive (iv) from the equality however. Another method is using the minorial rank $\text{m-rank}(A)$, which we will introduce next. It is clear that $\text{m-rank}(A) = \text{m-rank}(A^*)$, as the determinants are invariant under transposition. So if we are able to prove $\text{c-rank}(A) = \text{m-rank}(A)$ then we clearly have $\text{r-rank}(A) = \text{c-rank}(A^*) = \text{m-rank}(A^*) = \text{m-rank}(A) = \text{c-rank}(A)$, as well. In fact we will also give prove for $\text{c-rank}(A) = \text{m-rank}(A)$, but wanted to give an independent proof of $\text{c-rank}(A) = \text{r-rank}(A)$ beforehand, even though this requires the somewhat advanced lemma (3.99.(i)).

(4.74) Example:
If R is *not* an integral domain, then a matrix in echelon form may well have fewer (column) rank, then its size suggests. Also in this case row-rank and column-rank need no longer agree. Over $R = \mathbb{Z}_6$ for example, we take a look at the following (3×4)-matrix

$$A := \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 3 & 2 & 0 \\ 0 & 0 & 0 & 3 \end{pmatrix} \in \mathrm{mat}_{3,4}(\mathbb{Z}_6)$$

This matrix features $1 = \text{c-rank}(A) < \text{r-rank}(A) = 2 < 3$. Prob First of all it is clear that $\{ c_1 \}$ is linearly independent, but as $2c_2 = 0$, $3c_2 = 0$ and also $2c_4 = 0$ this set can not be extended, such that $\text{c-rank}(A) = 1$. Also $\{ r_1, r_2 \}$ is linearly independent: suppose $0 = ar_1 + br_2 = (a, 3b, 2b, 0)$, then $a = 0$ is obvious. But $3b = 0$ only leaves $b \in \{ 0, 2, 4 \}$ and $2b = 0$ only leaves $b \in \{ 0, 3 \}$. Since b is this same we also get $b = 0$. But as $2r_3 = 0$ as well, neither $\{ r_1, r_2 \}$ can be extended. Therefore $\text{r-rank}(A) = 2$, as claimed.

(4.75) Example:
If R is *not* an integral domain, then the image-rank of A may well exceed the column-rank of A. As an example take the ring $R := \mathbb{Z}_{70}$ and consider the matrix

$$A := \begin{pmatrix} 3 & 10 \\ 3 & 14 \end{pmatrix}$$

having the column vectors $c_1 = (3, 3)$ and $c_2 = (10, 14)$. As $3 \in R^*$ (with inverse 47) clearly $\{ c_1 \}$ is linearly independent. However $35c_2 = (0, 0)$ such that $\{ c_2 \}$ is linearly dependent. Therefore $\text{c-rank}(A) = 1$ with c_1 being the one linearly independent column. Yet $c_2 \notin Rc_1$ such that $\mathrm{im}(A)$ cannot be generated by a single element, as $\mathrm{im}(A)$ contains both $(1, 1)$ and $(20, 0)$. Therefore $2 = \text{i-rank}(A) \geq \text{c-rank}(A) = 1$.

(4.76) Example:
But even if R *is* an integral domain the image-rank of a matrix A may exceed its column-rank (or any rank equal to it). A very easy, but instructive example is the following: Let $R := \mathbb{Z}[t]$ be the polynomial ring over the integers and consider

$$A := \begin{pmatrix} 2 & t \end{pmatrix} \in \mathrm{mat}_{1,2}(R)$$

Its image clearly is $2R + tR = \{ f \in R \mid f[0] \in 2\mathbb{Z} \}$. As this image cannot be generated by a single $g \in R$ we have $\text{i-rank}(A) = 2$. Yet the column rank cannot exceed 1 and hence $\text{c-rank}(A) < \text{i-rank}(A)$.

(4.77) Example:
If R is a PID, then the image-rank and column-rank of A agree. However this is *not* due to the fact, that a maximal linearly independent subset of columns suffices to build up the image of A. E.g. regard

$$A := \begin{pmatrix} 2 & 0 & 4 \\ 0 & 3 & 4 \end{pmatrix}$$

Clearly the columns $(2,0)$ and $(0,3)$ are linearly independent and hence c-rank$(A) = 2$. They generate the sub-module $2\mathbb{Z} \oplus 3\mathbb{Z}$ of $\mathbb{Z}^2$. Yet this image of A also is generated by $(4,4) \notin 2\mathbb{Z} \oplus 3\mathbb{Z}$ and therefore

$$\mathsf{Lh}\left\{ \begin{pmatrix} 2 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 3 \end{pmatrix} \right\} \;=\; 2\mathbb{Z} \oplus 3\mathbb{Z} \quad\subset\quad \mathsf{im}(A) \;=\; 2\mathbb{Z} \oplus \mathbb{Z} \quad\subset\quad \mathbb{Z}^2$$

(4.78) Remark:
The equality of the row- and the column-rank of matrices over an integral domain R is a *really* strong property though. This can be gleaned from item (ix), which is a direct consequence of this equality. Generally speaking (ix) states: Over an integral domain R the linear dependency of the tuples x_1, $x_2, \ldots, x_m \in R^n$ is determined in m dimensions already, no matter how many $n \geq m$ entries these tuples have. And if R is not an integral domain, this property vanishes: As an example consider the ring $R = \mathbb{Z}_{30}$ and the following matrix

$$A \;=\; \begin{pmatrix} 6 & 4 \\ 9 & 6 \\ 7 & 5 \end{pmatrix} \;\in\; \mathsf{mat}_{3,2}(R)$$

First of all we note that c-rank$(A) = 2$: Suppose we had $aA_1 + bA_2 = 0$ then this would mean the equations $6a + 4b = 0$ and $9a + 6b = 0$ and $7a + 5b = 0$. Subtracting the first from the third equation we find $a + b = 0$. But equation one then turns into $2a = 0$ and equation two into $3a = 0$. This again means $a = 0$ and in turn $b = 0$, such that we see that A_1 and A_2 are linearly independent. However all the (2×2)-sub-matrices of A have column-rank 1 only, as we can easily present some linear dependencies

$$\begin{aligned} 10 \begin{pmatrix} 6 \\ 9 \end{pmatrix} + 0 \begin{pmatrix} 4 \\ 6 \end{pmatrix} &= \begin{pmatrix} 0 \\ 0 \end{pmatrix} \\ 15 \begin{pmatrix} 6 \\ 7 \end{pmatrix} + 15 \begin{pmatrix} 4 \\ 5 \end{pmatrix} &= \begin{pmatrix} 0 \\ 0 \end{pmatrix} \\ 10 \begin{pmatrix} 9 \\ 7 \end{pmatrix} + 10 \begin{pmatrix} 6 \\ 5 \end{pmatrix} &= \begin{pmatrix} 0 \\ 0 \end{pmatrix} \end{aligned}$$

(4.79) Proposition: (viz. 925)
If $(F, +, \cdot)$ is a field and $A \in \mathsf{mat}_{m,n}(F)$ is a matrix over F, where $1 \leq m$, $n \in \mathbb{N}$. Let us abbreviate $r_i := \mathsf{row}_i(A) \in F^n$ and $c_j := \mathsf{col}_j(A)$ for any $i \in 1 \ldots m$ and $j \in \ldots n$. Now consider any $r \in \mathbb{N}$, then the following five statements are equivalent

(a) c-rank$(A) \;\leq\; r$

(b) A has r columns, that generate all of its columns. I.e. there is some subset $J \subseteq 1 \ldots n$ with $\#J = r$ such that for any $k \in 1 \ldots n$ we have

$$c_k \;\in\; \mathsf{Lh}_F\{\, c_j \mid j \in J \,\}$$

(c) There are matrices $C \in \mathrm{mat}_{m,r}(F)$ and $R \in \mathrm{mat}_{r,n}(F)$ such that A can be factored into a product of the following form

$$A \;=\; C\,R$$

(d) A has r rows, that generate all of its rows. I.e. there is some subset $I \subseteq 1 \ldots m$ with $\#I = r$ such that for any $k \in 1 \ldots m$ we have

$$r_k \;\in\; \mathrm{Lh}_F\{\, r_j \mid j \in J \,\}$$

(e) $\text{r-rank}(A) \;\leq\; r$

In particular - for a field F - the column-rank (or likewise row-rank) of A can be characterized as the minimal number r for which A admits a decomposition of the form $A = CR$:

$$\text{c-rank}(A) \;=\; \text{r-rank}(A) \;=\; \min\{\, r \in \mathbb{N} \mid \;\; \text{(c)} \,\}$$

(4.80) Remark:
Note that this provides a rather elegant method of proving $\text{c-rank}(A) = \text{r-rank}(A)$ in case the base ring is a field. The only non-elementary ingredients in the proof are the basis selection theorem and (ii) the sub-multiplicativety of the rank $\text{c-rank}(CR) \leq \text{c-rank}(R)$ and $\text{r-rank}(CR) \leq \text{r-rank}(C)$. But the latter property is easy to see, as well.

(4.81) Definition:
Let $(R, +, \cdot)$ be a commutative ring, $1 \leq m$, $n \in \mathbb{N}$ and consider a matrix $A \in \mathrm{mat}_{m,n}(R)$ of any size over R. If furthermore $r \in 1 \ldots \min\{\, m, n \,\}$ and $\alpha \in \mathrm{Asc}(r, m)$, $\beta \in \mathrm{Asc}(r, n)$ are ascending chains of indexes then recall the notation of a *submatrix*

$$A[\alpha \mid \beta] \;=\; \begin{pmatrix} a_{\alpha(1),\beta(1)} & a_{\alpha(1),\beta(2)} & \cdots & a_{\alpha(1),\beta(r)} \\ a_{\alpha(2),\beta(1)} & a_{\alpha(2),\beta(2)} & \cdots & a_{\alpha(2),\beta(r)} \\ \vdots & \vdots & & \vdots \\ a_{\alpha(r),\beta(1)} & a_{\alpha(r),\beta(2)} & \cdots & a_{\alpha(r),\beta(r)} \end{pmatrix} \;\in\; \mathrm{mat}_r(R)$$

The determinant of such a submatrix of A is called a **minor** of **size** r or simply r-**minor** of A. We will denote the set of all r-minors of A by

$$\mathrm{Minor}_r(A) \;:=\; \{\, \det(A[\alpha \mid \beta]) \;\mid\; \alpha \in \mathrm{Asc}(r, m),\, \beta \in \mathrm{Asc}(r, n) \,\} \;\subseteq\; R$$

The **minorial rank** (also called **determinantal rank**) of A is the largest integer such that not all r-minors of A vanish [if $A = 0$ is the zero-matrix this set is empty and we let $\text{m-rank}(0) := 0$]

$$\text{m-rank}(A) \;:=\; \max\{\, r \in 1 \ldots \min\{\, m, n \,\} \mid \mathrm{Minor}_r(A) \neq \{0\} \,\}$$

Now for any $1 \leq r \leq \min\{ m, n \}$ the ideal generated by the set of r-minors of A is said to be the r-th **Fitting ideal** of A, which we will denote by

$$\mathfrak{f}_r(A) \;:=\; \langle \mathrm{Minor}_r(A) \rangle_{\mathrm{i}} \;\trianglelefteq_{\mathrm{i}}\; R$$

For completeness purposes we also define $\mathfrak{f}_0(A) := R$ and for any larger index $\min\{ m, n \} < r \in \mathbb{N}$ we let $\mathfrak{f}_r(A) := 0 \trianglelefteq_{\mathrm{i}} R$. If R is a PID, then any ideal of R is generated by a single element $\mathfrak{f}_r(A) = d_r R$. In this case a generator $d_r \in R$ of $\mathfrak{f}_r(A)$ is called an r-th **determinantal divisor** of A. Finally we define the **Fitting rank** of A to be the largest integer r such that the annihilator ideal of $\mathfrak{f}_r(A)$ vanishes

$$\text{f-rank}(A) \;:=\; \max\{ r \in \mathbb{N} \mid \mathrm{ann}\,(\mathfrak{f}_r(A)) = 0 \}$$

(4.82) Example:
Let us give some examples of sets of minors of an arbitrary matrix $A = (a_{i,j}) \in \mathrm{mat}_{m,n}(R)$ over some commutative ring R. Clearly we have

$$\begin{aligned} \mathrm{Minor}_1(A) &= \left\{ a_{i,j} \;\middle|\; \begin{array}{l} i \in 1 \ldots m, \\ j \in 1 \ldots n \end{array} \right\} \\ \mathrm{Minor}_2(A) &= \left\{ a_{p,q}a_{r,s} - a_{r,q}a_{p,s} \;\middle|\; \begin{array}{l} 1 \leq p < r \leq m, \\ 1 \leq r < s \leq n \end{array} \right\} \end{aligned}$$

And if $A \in \mathrm{mat}_n(R)$ is a square matrix over R, then it is clear that A is the only $n \times n$ submatrix of itself

$$A \text{ square matrix} \;\Longrightarrow\; \mathrm{Minor}_n(A) \;=\; \{ \det(A) \}$$

(4.83) Proposition: (viz. 926)
Let $(R, +, \cdot)$ be a commutative ring and consider a matrix $A \in \mathrm{mat}_{m,n}(R)$ where $1 \leq m, n \in \mathbb{N}$ over R. Given $r, s \in \mathbb{N}$ with $1 \leq r, s \leq \min\{ m, n \}$ fix some $\alpha \in \mathrm{Asc}(r, m)$ and $\beta \in \mathrm{Asc}(s, n)$. Then we find:

(i) We have $A[\alpha \mid \beta]^* = A^*[\beta \mid \alpha]$ and in particular the matrix A and its transpose A^* share the same minors. Formally this is the identity of the sets

$$\mathrm{Minor}_r(A) \;=\; \mathrm{Minor}_r(A^*)$$

Consequentially we have the equalities $\mathfrak{f}_r(A^*) = \mathfrak{f}_r(A)$ and thereby $\text{f-rank}(A^*) = \text{f-rank}(A)$ and of course $\text{m-rank}(A^*) = \text{m-rank}(A)$.

(ii) For any $1 \leq r \leq m, n$ the r-minors are invariant under elementary equivalence up to sign. That is: If we denote $\pm M := \{ m \mid m \in M \} \cup \{ -m \mid m \in M \}$ for any subset $M \subseteq R$, then

$$A \equiv B \;\Longrightarrow\; \pm\mathrm{Minor}_r A = \pm\mathrm{Minor}_r B$$

(iii) By the Laplace expansion theorem the r-minors of A are R-linear combinations of the $(r-1)$-minors of A. In particular we find the following inclusions

$$\mathrm{Minor}_r(A) \;\subseteq\; \mathfrak{f}_{r-1}(A)$$

$$\mathfrak{f}_r(A) \;\subseteq\; \mathfrak{f}_1(A)^r$$

$$\mathrm{Minor}_{r-1}(A) \;=\; \{0\} \quad\Longrightarrow\quad \mathrm{Minor}_r(A) \;=\; \{0\}$$

And thereby the fitting ideals of A form a descending chain of ideals in R. Also, if we denote $\mu := \min\{\, m, n \,\}$, then by definition of these ideals we know that this chain has the form

$$R \;=\; \mathfrak{f}_0(A) \;\supseteq\; \mathfrak{f}_1(A) \;\supseteq\; \ldots \;\supseteq\; \mathfrak{f}_\mu(A) \;\supseteq\; \mathfrak{f}_{\mu+1}(A) \;=\; \ldots \;=\; 0$$

(iv) By definition the annihilator of a Fitting ideal of A is the set of all $a \in R$ that make $am = 0$ for any $m \in \mathfrak{f}_r(A)$. But as the minors $\mathrm{Minor}_r(A)$ generate that ideal, it is clear that

$$\mathrm{ann}\,(\mathfrak{f}_r(A)) \;=\; \{\, a \in R \;\mid\; \forall\, m \in \mathrm{Minor}_r(A) \,:\, am = 0 \,\}$$

And since the Fitting ideals form a descending chain of ideals, their annihilators form an ascending chain. With $\mu := \min\{\, m, n \,\}$ again this is the following chain of ideals

$$0 = \mathrm{ann}(\mathfrak{f}_0(A)) \;\subseteq\; \ldots \;\subseteq\; \mathrm{ann}(\mathfrak{f}_\mu(A)) \;\subseteq\; \mathrm{ann}(\mathfrak{f}_{\mu+1}(A)) = \cdots = R$$

(v) If $A' = A[\alpha \mid \beta]$ is a submatrix of A, then its minorial rank and its fitting rank do not exceed the respective rank of A, that is we find the following inequalities

$$\begin{aligned} \text{m-rank}(A') \;&\leq\; \text{m-rank}(A) \\ \text{f-rank}(A') \;&\leq\; \text{f-rank}(A) \end{aligned}$$

(vi) If A has a minor $m \in \mathrm{Minor}_r(A)$ with trivial annihilator only, then the column- and row-ranks of A are at least r, formally this is

$$\mathrm{ann}\,(\det\,(A[\alpha \mid \beta])) = 0 \quad\Longrightarrow\quad \min\{\, \text{c-rank}(A), \text{r-rank}(A) \,\} \geq r$$

(vii) The minorial rank is submultiplicative, that is: If $A \in \mathrm{mat}_{k,m}(R)$ and $B \in \mathrm{mat}_{m,n}(R)$ for some $1 \leq k$, m and $n \in \mathbb{N}$, then we have

$$\text{m-rank}(AB) \;\leq\; \min\{\, \text{m-rank}(A), \text{m-rank}(B) \,\}$$

(viii) The matrix A (as a linear map $R^n \to R^m$) has no kernel if and only if its column-rank is n which is again equivalent to a Fitting-rank of n. Altogether

$$\mathrm{kn}(A) = 0 \;\Longleftrightarrow\; \text{c-rank}(A) = n \;\Longleftrightarrow\; \text{f-rank}(A) = n$$

(4.84) Example:
Consider any commutative ring $(R,+,\cdot)$, $1 \leq m,n \in \mathbb{N}$ and a pair of tuples $u = (u_1,u_2,\ldots,u_m) \in R^m$ and $v = (v_1,v_2,\ldots,v_n) \in R^n$. If now $A \in \mathrm{mat}_{m,n}(R)$ is the following matrix

$$A \;=\; \big(u_i v_j\big) \;=\; \begin{pmatrix} u_1v_1 & u_1v_2 & \ldots & u_1v_n \\ u_2v_1 & u_2v_2 & \ldots & u_2v_n \\ \vdots & \vdots & & \vdots \\ u_mv_n & u_mv_2 & \ldots & u_mv_n \end{pmatrix}$$

Then for any $x = (x_1,x_2,\ldots,x_n) \in R^n$ we get $Ax = \langle x \mid v\rangle\, u \in R^m$ [if R is non-commutative, then $Ax = u\,\langle v \mid x\rangle$ still]. And thereby we have

$$\text{c-rank}(A) \;=\; \text{r-rank}(A) \;=\; \text{m-rank}(A) \;\leq\; 1$$

Prob If $A = 0$ then all these ranks are 0, so let us assume $A \neq 0$. Next note that $\mathrm{col}_j(A) = v_j u$ such that any two columns of A are linearly dependent $v_i\mathrm{col}_j(A) - v_j\mathrm{col}_i(A) = 0$. Therefore c-rank$(A) \leq 1$, which only leaves c-rank$(A) = 1$, since $A \neq 0$. Likewise r-rank$(A) = 1$, as we also have $\mathrm{row}_i(A) = u_i v$. The minorial rank of A also is m-rank$(A) \leq 1$, e.g. $\det(A[(1,2) \mid (1,2)] = u_1v_1u_2v_2 - u_1v_2u_2v_1 = 0$, since R is commutative. The same is true for all the 2×2 minors of A. And as $A \neq 0$ this is m-rank$(A) = 1$, as well.

(4.85) Remark:
Given 2 vectors $x = (x_1,x_2,x_3)$ and $y = (y_1,y_2,y_3)$ in 3 dimensional space R^3 it stands to reason that there is precisely one direction perpendicular to both x and y. As we will see in chapter 4.8 the orthogonality $x \perp n$ and $y \perp n$ (for some $n = (n_1,n_2,n_3) \in R^3$) can be expressed in the equation

$$\begin{pmatrix} x_1 & x_2 & x_3 \\ y_1 & y_2 & y_3 \end{pmatrix} \begin{pmatrix} n_1 \\ n_2 \\ n_3 \end{pmatrix} \;=\; \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

By Cramer's rule a solution n to this set of equations can be given in terms of the 2-minors of the matrix above and this is the so-called *vector-product* of x and y

$$n \;=\; x \wedge y \;:=\; \begin{pmatrix} x_2y_3 - x_3y_2 \\ x_3y_1 - x_1y_3 \\ x_1y_2 - x_2y_1 \end{pmatrix}$$

If R is an integral domain and x and y are linearly independent, then $x \wedge y \neq 0$ since f-rank$(A) =$ r-rank$(A) = 2$. If R is no integral domain, then it may happen, that $x \wedge y = 0$ even if x and y are linearly independent (refer to the example above). This is hard to imagine: The projections of x and y on any coordinate plane are in line, even though in space x and y themselves are not.

(4.86) Theorem: (viz. 932)
Let $(R,+,\cdot)$ be a commutative ring, $1 \leq m,n \in \mathbb{N}$ and $A \in \mathrm{mat}_{m,n}(R)$ be a matrix over R of any size. Then the column- and row-ranks do not exceed the Fitting rank, which in turn is bound by the minorial rank. That is we generally have the inequalities

$$\max\{\,\text{c-rank}(A), \text{r-rank}(A)\,\} \;\leq\; \text{f-rank}(A) \;\leq\; \text{m-rank}(A) \;\leq\; \min\{\,m,n\,\}$$

If R even is an integral domain, then the row-, column-, fitting- and minorial ranks of a matrix always agree. That is in this case we even get the equalities

$$\text{c-rank}(A) \;=\; \text{r-rank}(A) \;=\; \text{f-rank}(A) \;=\; \text{m-rank}(A)$$

And finally, if R is a field, then all five notions of the rank of a matrix yield the same result, that is

$$\text{i-rank}(A) \;=\; \text{c-rank}(A) \;=\; \text{r-rank}(A) \;=\; \text{f-rank}(A) \;=\; \text{m-rank}(A)$$

(4.87) Example:
The following ingenious example is taken from [Adkins, Weintraub, Algebra, GTM 136], who sadly (while stating most theorems of this section) give next to no proof at all, concerning the rank of matrices. Consider the ring $R = \mathbb{Z}_{210}$ and the following (4×4)-matrix over R:

$$A \;:=\; \begin{pmatrix} 0 & 2 & 3 & 5 \\ 2 & 0 & 6 & 0 \\ 3 & 0 & 3 & 0 \\ 0 & 0 & 0 & 7 \end{pmatrix}$$

This matrix boasts four different ranks! We will find, that A has the following ranks of the resp. kind

$$\begin{aligned} \text{r-rank}(A) &= 1 \\ \text{c-rank}(A) &= 2 \\ \text{f-rank}(A) &= 3 \\ \text{m-rank}(A) &= 4 \\ \text{i-rank}(A) &= 4 \end{aligned}$$

Let us first check the row rank, as $105\,\mathrm{row}_2(A) = 0$ and $70\,\mathrm{row}_3(A) = 0$ but also $30\,\mathrm{row}_4(A) = 0$ we only have to look at the first row. But here, if $a\,\mathrm{row}_1(A) = 0$, we in particular find $2a = 0$ and $3a = 0$, such that $a = 3a - 2a = 0$. Therefore we have r-rank$(A) = 1$, as the first is the one and only linearly independent row.
For the column rank we likewise find $105\,\mathrm{col}_2(A) = 0$ and $70\,\mathrm{col}_3(A) = 0$. But hereby, if we have $a\,\mathrm{col}_1(A) + b\,\mathrm{col}_4(A) = 0$ we have $2a = 0$, $3a = 0$ and $5b = 0$, $7b = 0$. From the first set of equations we find $a = 0$, as before. From the second set we get $b \in \mathrm{ann}(5) \cap \mathrm{ann}(7) = 42R \cap 30R$. But as the least common multiple of 30 and 42 is $210 = 0$ this implies $b \in 210R = 0$. Therefore the first and fourth columns are linearly independent and we truly have c-rank$(A) = 2$.

Actually the easiest part is the determinantal rank, since $\det(A) = 168 \neq 0$ we have m-rank$(A) = 4$. But as $5 \cdot 168 = 840 = 0$ we have $\operatorname{ann}(\det(A)) \neq 0$ such that f-rank$(A) \leq 3$. To find the equality let us take a look at the 16 (3×3)-minors of A:

submatrix	minor = det	annihilator
$A_{1,1}$	0	R
$A_{1,2}$	$-84 = 126$	$105R$
$A_{1,3}$	0	R
$A_{1,4}$	0	R
$A_{2,1}$	42	$5R$
$A_{2,2}$	$-63 = 147$	$10R$
$A_{2,3}$	$-42 = 168$	$5R$
$A_{2,4}$	0	R
$A_{3,1}$	84	$5R$
$A_{3,2}$	$-42 = 168$	$5R$
$A_{3,3}$	$-28 = 182$	$15R$
$A_{3,4}$	0	R
$A_{4,1}$	0	R
$A_{4,2}$	$-60 = 150$	$7R$
$A_{4,3}$	0	R
$A_{4,4}$	24	$35R$

Note that $\{ 24, 147, 182 \} \subseteq \operatorname{Minor}_3(A)$. And from this we find $\mathfrak{f}_3(A) = R$, for example we have $1 = 7 \cdot 147 + 2 \cdot 182 - 58 \cdot 24 \in \mathfrak{f}_3(A)$ and therefore $\operatorname{ann}(\mathfrak{f}_3(A)) = 0$, such that m-rank$(A) = 3$.
Recall that these minors are precisely the coefficients of the cofactor matrix of A and therefore we can also build up the adjugate matrix of A. In this case we get

$$A^{\#} = \begin{pmatrix} 0 & -42 & 84 & 0 \\ 84 & -63 & 42 & -60 \\ 0 & 42 & -28 & 0 \\ 0 & 0 & 0 & 24 \end{pmatrix} = \begin{pmatrix} 0 & 168 & 84 & 0 \\ 84 & 147 & 42 & 150 \\ 0 & 42 & 182 & 0 \\ 0 & 0 & 0 & 24 \end{pmatrix}$$

As $AA^{\#}x = \det(A)x = 168x$ for any $x \in R^4$ we see, that the image of A contains the vectors $(168, 0, 0, 0)$ to $(0, 0, 0, 168)$. But these cannot be generated by three vectors and hence A has i-rank$(A) = 4$.

(4.88) Lemma: (viz. 934)
Smith normal Form: Let (R,v) be an Euclidean domain, $1 \leq m$, $n \in \mathbb{N}$ and $A \in \mathrm{mat}_{m,n}(R)$ be any matrix over R. Then we find the truth of the following statements

(i) If $m \leq n$ then we can find scalar factors $d_1,\ldots,d_m \in R$ that form a divisibly ascending chain, i.e. $d_1 \mid d_2,\ldots,d_{m-1} \mid d_m$ such that A is elementary equivalent to

$$A \equiv \begin{pmatrix} d_1 & & 0 & 0 & \ldots & 0 \\ & \ddots & & \vdots & & \vdots \\ 0 & & d_m & 0 & \ldots & 0 \end{pmatrix}$$

And for any $r \in 1\ldots m$ we find that the scalar factors $d_1,\ldots,d_m$ can be expressed in terms of minors of A: The product $d_1 \ldots d_r$ is a greatest common divisor of the r-minors of A. In particular the d_i are uniquely determined by A up to multiplication with units of R. Formally

$$d_1 \ldots d_r \quad \in \quad \gcd(\mathrm{Minor}_r A)$$

(ii) If $n \leq m$ then we can find scalar factors $d_1,\ldots,d_n \in R$ that form a divisibly ascending chain, i.e. $d_1 \mid d_2,\ldots,d_{n-1} \mid d_n$ such that A is elementary equivalent to

$$A \equiv \begin{pmatrix} d_1 & & 0 \\ & \ddots & \\ 0 & & d_n \\ 0 & \ldots & 0 \\ \vdots & & \vdots \\ 0 & \ldots & 0 \end{pmatrix}$$

And for any $r \in 1\ldots m$ we find that the scalar factors $d_1,\ldots,d_n$ can be expressed in terms of minors of A: The product $d_1 \ldots d_r$ is a greatest common divisor of the r-minors of A. In particular the d_j are uniquely determined by A up to multiplication with units of R. Formally

$$d_1 \ldots d_r \quad \in \quad \gcd(\mathrm{Minor}_r A)$$

4.7 Duality Theory

In R^n we have introduced the scalar product $\langle x, y\rangle$ of two tuples x, $y \in R^n$. Let us look at this from another perspective: For any $y \in R^n$ the scalar product gives rise to a linear map, of the form

$$R^n \to R \ : \ x \mapsto \langle x, y\rangle$$

The set of all linear maps of the form $M \to R$ will be called the *dual module* M' of M. So the scalar product induces a map from R^n to $(R^n)'$. In this section we will study the relation between M and its dual M' and see that this is closely linked to studying bilinear forms - such as the scalar product.
This is extremely fruitful in the case of the base field $\mathbb{R}$ or $\mathbb{C}$ and is the staging point of a lot of important theories - like Fourier analysis and Hilbert space theory in general. So at several points throughout this section we will have to leave the all-encompassing domain of modules and have to restrict ourselves to vector spaces over the reals or complex numbers.

(4.89) Remark:
Recall the construction of the complex numbers $\mathbb{C} = \mathbb{R} \oplus i\mathbb{R}$ in (1.35.(i)). Thereby we have several maps

$$\begin{aligned} \mathrm{re} &: \mathbb{C} \to \mathbb{R} : \ x + iy \mapsto x \\ \mathrm{im} &: \mathbb{C} \to \mathbb{R} : \ x + iy \mapsto y \\ \kappa &: \mathbb{C} \to \mathbb{C} : \ x + iy \mapsto x - iy \end{aligned}$$

The map κ is called the **complex conjugation** and we write $\overline{z} := \kappa(z)$. Note that κ is an automorphism of the $\mathbb{R}$-algebra $\mathbb{C}$. That is for any w, $z \in \mathbb{C}$ and any $a \in \mathbb{R}$ we get

$$\begin{aligned} \overline{w+z} &= \overline{w} + \overline{z} \\ \overline{a \cdot z} &= a \cdot \overline{z} \\ \overline{w \cdot z} &= \overline{w} \cdot \overline{z} \end{aligned}$$

Also note that re and im are $\mathbb{R}$-linear only and do *not* respect the multiplication of $\mathbb{C}$. It is clear that κ is self-inverse $\kappa^2 = \mathbb{1}_{\mathbb{C}}$ and satisfies a special property: For any $z = x + iy$ we find

$$z \cdot \overline{z} \ = \ x^2 + y^2 \ \in \ \mathbb{R}^+$$

In particular we may define the **absolute value** $|z|$ of $z = x + iy \in \mathbb{C}$ which we interpret as the the distance of z from the origin 0

$$|z| \ := \ \sqrt{z \cdot \overline{z}} \ = \ \sqrt{x^2 + y^2}$$

Recall that the complex conjugation and absolute value of a complex number $z \in \mathbb{C}$ with $z \neq 0$ also provide a way to find the inverse of z

$$z^{-1} \ = \ \frac{1}{|z|^2}\overline{z} \ = \ \frac{x - iy}{x^2 + y^2}$$

In the next section 4.8 we will introduce sine and cosine [even though the reader will probably know these already] and see that any point $(x,y) = x + iy$ in the plane $\mathbb{R}^2 = \mathbb{C}$ can be reached by by virtue of the **polar coordinates**

$$\mathbb{R}^+ \times [0, 2\pi[\to \mathbb{C} \ : \ (r,\alpha) \mapsto r \cdot \cos(\alpha) + ir \cdot \sin(\alpha)$$

If we take $\mathbb{R}_{>0} \times [0, 2\pi[\to \mathbb{C}^*$ this map even is bijective, its inverse given by $z \mapsto (|z|, \arg(z))$, where the angle $\alpha = \arg(z)$ of z can be computed by painstakingly distinguishing all the different cases, in what quadrant z is

$$\arg(z) \quad = \quad \begin{cases} 0 & \text{if } x = 0 \text{ and } y = 0 \\ \tan^{-1}(y/x) & \text{if } x > 0 \text{ and } y \geq 0 \\ \pi/2 & \text{if } x = 0 \text{ and } y > 0 \\ \pi/2 - \tan^{-1}(x/y) & \text{if } x < 0 \text{ and } y > 0 \\ \pi + \tan^{-1}(y/x) & \text{if } x < 0 \text{ and } y \leq 0 \\ 3\pi/2 & \text{if } x = 0 \text{ and } y < 0 \\ 2\pi + \tan^{-1}(y/x) & \text{if } x > 0 \text{ and } y < 0 \end{cases}$$

Another way to use polar coordinates in the famous formula of Euler (■) which links the exponential function with sine and cosine in the following way

$$r \cdot e^{i\alpha} \quad = \quad r \cdot \cos(\alpha) + ir \cdot \sin(\alpha)$$

That is $z = |z| \cdot e^{i \cdot \arg(z)}$ for any $z \in \mathbb{C}$. The formula of Euler is usually proved in a course of analysis by comparing the power series expansions of the exponential function, sine and cosine respectively. It can be seen that sine gets the odd exponents and cosine gets the even exponents of the exponential series. However, we don't want to go into details here.

$$\begin{aligned} e^z &= \sum_{k=0}^{\infty} \frac{1}{k!} z^k \\ \sin(z) &= \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k+1)!} z^{2k+1} \\ \cos(z) &= \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k)!} z^{2k} \end{aligned}$$

The representation in polar coordinates has the advantage that $z \mapsto e^z$ is a homomorphism from the additive group $(\mathbb{C}, +)$ to the multiplicative group $(\mathbb{C}^*, \cdot)$. That is we have the following formula

$$\begin{aligned} e^0 &= 1 \\ e^{w+z} &= e^w \cdot e^z \end{aligned}$$

for any $w, z \in \mathbb{C}$. In the case of the reals this even is an isomorphism of from $(\mathbb{R}, +)$ to $(\mathbb{R}_{>0}, \cdot)$ but in the complex case things are a little more complex. However the homorphism property yields

$$\left(r \cdot e^{i\alpha}\right) \cdot \left(s \cdot e^{i\beta}\right) \quad = \quad rs \cdot e^{i(\alpha+\beta)}$$

(4.90) Remark:
For any commutative ring $(R,+,\cdot)$ and any $1 \leq n \in \mathbb{N}$ we introduced the **scalar product** to be the following symmetric bilinear form on R^n

$$R^n \times R^n \ :\to \ R \ : \ (x,y) \ \mapsto \ \langle x,y\rangle \ := \ \sum_{i=1}^{n} x_i y_i$$

where $x = (x_1, x_2, \ldots, x_n)$ and $y = (y_1, y_2, \ldots, y_n)$. This notation hides the dimension n however, so in fact theses are infinitely many maps. With the term *bilinear* we express the following properties for any u, v, x and $y \in R^n$ and any a, $b \in R$ we get

$$\begin{aligned} \langle au+v,x\rangle &= a\langle u,x\rangle + \langle v,x\rangle \\ \langle u,bx+y\rangle &= b\langle u,x\rangle + \langle u,y\rangle \end{aligned}$$

The term *symmetric* clearly refers to $\langle x,y\rangle = \langle y,x\rangle$ for any x, $y \in R^n$ and *form* is reserved for maps that go down to the base ring. Also if $x \in R^n$, $y \in R^m$ and $A \in \mathrm{mat}_{m,n}(R)$ then we get

$$\langle Ax,y\rangle \ = \ \langle x,A^*y\rangle$$

where A^* is the transpose of A. All this has been established in section 4.1. If $R = \mathbb{R}$ is the field of reals, the scalar product has another important property - it is *positive*: For any $x_i \in \mathbb{R}$ we find

$$\langle x,x\rangle \ = \ \sum_{i=1}^{n} x_i^2 \ \geq \ 0$$

In fact the scalar product even is *positive definite*, that is for any $x \in \mathbb{R}^n$ we also have the equivalence

$$\langle x,x\rangle \ = \ 0 \ \iff \ x \ = \ 0$$

Prob If $x = 0$ then $\langle x,x\rangle = 0$ is clear. Conversely if we had $x_1 \neq 0$ (for example) then $x_1^2 > 0$. And as $x_i^2 \geq 0$ for any $i \in 2 \ldots n$ there is no negative number in $\langle x,x\rangle = x_1^2 + x_2^2 + \cdots + x_n^2$ to cancel x_1^2 such that $\langle x,x\rangle > 0$ as well. Therefore $\langle x,x\rangle = 0$ implies $x_i = 0$ for all $i \in 1 \ldots n$.

(4.91) Definition:
Now consider $\mathbb{C}^n$ for some $1 \leq n \in \mathbb{N}$ and $w = (w_1, w_2, \ldots, w_n)$ and $z = (z_1, z_2, \ldots, z_n) \in \mathbb{C}^n$. Then we define the **inner product** on $\mathbb{C}^n$ to be the following map

$$\mathbb{C}^n \times \mathbb{C}^n \ :\to \ \mathbb{C} \ : \ (w,z) \ \mapsto \ \langle w \mid z\rangle \ := \ \sum_{k=1}^{n} w_k \overline{z}_k$$

And if $A = (a_{i,j}) \in \mathrm{mat}_{m,n}(\mathbb{C})$ is an $(m \times n)$-matrix over the complex numbers, then we define the **complex conjugate** matrix $\overline{A}$ of A to be the transpose matrix of A in which all entries are conjugated

$$\overline{A} \ := \ \left(\overline{a}_{j,i}\right) \ \in \ \mathrm{mat}_{n,m}(\mathbb{C})$$

(4.92) Proposition: (viz. 936)

Let $1 \leq m, n \in \mathbb{N}$, then the inner product on $\mathbb{C}$ is a *sesqui-linear form* of $\mathbb{C}^n$ with respect to the complex conjugation. That is for any $t, w, z \in \mathbb{C}^n$ and any $a, b \in \mathbb{C}$ we get

$$\begin{aligned}
\langle t + w \mid z \rangle &= \langle t \mid z \rangle + \langle w \mid z \rangle \\
\langle t \mid w + z \rangle &= \langle t \mid z \rangle + \langle t \mid w \rangle \\
\langle aw \mid z \rangle &= a\langle w \mid z \rangle \\
\langle w \mid bz \rangle &= \overline{b}\langle w \mid z \rangle \\
\langle z \mid w \rangle &= \overline{\langle w \mid z \rangle}
\end{aligned}$$

If we extend the maps of the *real* and *imaginary part* and the complex conjugation of $\mathbb{C}$ to $\mathbb{C}^n$ componentwise by letting [as always, we take $z = (z_1, z_2, \ldots, z_n) \in \mathbb{C}^n$ in the equations below]

$$\begin{aligned}
\mathrm{re}(z) &:= \big(\mathrm{re}(z_1), \mathrm{re}(z_2), \ldots, \mathrm{re}(z_n)\big) \in \mathbb{R}^n \\
\mathrm{im}(z) &:= \big(\mathrm{im}(z_1), \mathrm{im}(z_2), \ldots, \mathrm{im}(z_n)\big) \in \mathbb{R}^n \\
\overline{z} &:= \big(\overline{z}_1, \overline{z}_2, \ldots, \overline{z}_n\big) \in \mathbb{C}^n
\end{aligned}$$

then the inner product and scalar product are related $\langle w \mid z \rangle = \langle w, \overline{z} \rangle$ and we also get the following identities for the real and imaginary parts of the inner product

$$\begin{aligned}
\mathrm{re}\big(\langle w \mid z \rangle\big) &= \langle \mathrm{re}(w), \mathrm{re}(z) \rangle + \langle \mathrm{im}(w), \mathrm{im}(z) \rangle \\
\mathrm{im}\big(\langle w \mid z \rangle\big) &= \langle \mathrm{im}(w), \mathrm{re}(z) \rangle - \langle \mathrm{re}(w), \mathrm{im}(z) \rangle
\end{aligned}$$

In particular the inner product is positive definite again, that is for any $z \in \mathbb{C}^n$ we have $\langle z \mid z \rangle \in \mathbb{R}^+$ is a positive real number, and we also get the equivalence of

$$\langle z \mid z \rangle = 0 \iff z = 0$$

Finally, if $w \in \mathbb{C}^n$, $z \in \mathbb{C}^m$ and $A \in \mathrm{mat}_{m,n}(\mathbb{C})$ then we get the following identity of the inner products $\langle A\, w \mid z \rangle$ of $\mathbb{C}^m$ and $\langle w \mid \overline{A}\, z \rangle$ of $\mathbb{C}^n$ respectively

$$\langle A\, w \mid z \rangle = \langle w \mid \overline{A}\, z \rangle$$

Let us generalize these two notions: Both the scalar product and the inner product are maps of the form $s : M \times M \to R$ where M is $\mathbb{R}^n$ or $\mathbb{C}^n$ and R is the base field $\mathbb{R}$ or $\mathbb{C}$ respectively. Both maps are linear in the first argument, but in the second argument there can be some twist of the base field. To be positive definite means that the images $s(x, x)$ are squares in the base field. Therefore we find the following common concept:

(4.93) Definition: (viz. 936)
Let $(R,+,\cdot)$ be a commutative ring, $\varepsilon \in \mathrm{rend}(R)$ be an endomorphism of R and M be an R-module. Then a map of the following form

$$s \;:\; M \times M \to R \;:\; (x,y) \mapsto s(x \mid y)$$

is said to be a **sesqui-linear** form with **respect to** ε [the word *sesqui* is derived from latin, meaning *one-and-a-half*], iff it satisfies the following three properties for any $x, y, z \in M$ and any $a \in R$

(1) $s(ax \mid y) \;=\; a \cdot s(x \mid y)$

(2) $s(x+y \mid z) \;=\; s(x \mid z) + s(y \mid z)$

(3) $s(y \mid x) \;=\; \varepsilon\big(s(x \mid y)\big)$

Note that a sesqui-linear form with respect to $\varepsilon = \mathbb{1}_R$ is the same as a symmetric bilinear form. Generally, for any sesqui-liear form we already get the following additional properties

(4) $s(x \mid ay) \;=\; \varepsilon(a) \cdot s(x \mid y)$

(5) $s(x \mid y+z) \;=\; s(x \mid y) + s(y \mid z)$

The sesqui-linear form s is said to be **positive definite**, iff for any $x \in M$ with $x \neq 0$ there is some unit $a \in R^*$, such that $s(x \mid x)$ is of the form $s(x \mid x) = a \cdot \varepsilon(a)$. Formally that is

$$x \;=\; 0 \quad \text{or} \quad s(x \mid x) \;\in\; \{\, a \cdot \varepsilon(a) \mid a \in R^* \,\}$$

If $P \;\leq_{\mathrm{m}}\; M$ is a sub-module of M and $s : M \times M \to R$ is any sesqui-linear form on M, then we define the **orthogonal complement** of P to be the following sub-module of M

$$P^{\perp} \;:=\; \{\, x \in M \mid \forall\, p \in P \;:\; s(x \mid p) = 0 \,\} \;=\; \bigcap_{p \in P} \mathrm{kn}\,(x \mapsto s(x \mid p))$$

If there are several sesqui-linear forms involved we will also write $s(\perp \mid P)$ instead of $P^{\perp}$ in order to fix the form used in the construction. Now a subset $\{\, m_i \mid i \in I \,\} \subseteq M$ is said to be an **orthonormal basis** (abbreviated as **ONB**) of M with **respect to** s, iff it satisfies

(1) $\{\, m_i \mid i \in I \,\}$ is an R-basis of M and

(2) $\forall\, i, j \in I$ we get $s(m_i \mid m_j) = \delta_{i,j}$

If $\{\, m_i \mid i \in I \,\}$ is an orthonormal basis with respect to some symmetric bilinear form $b : M \times M \to R$, then we will sometimes omit the "with respect to" part, if b is understood.

(4.94) Remark:
Let us take a look at the set $Q := \{\, a \cdot \varepsilon(a) \mid a \in R^* \,\}$: As ε is a homomorphism of rings we find $Q \subseteq R^*$ as the inverse element of $a\varepsilon(a) \in Q$ is just $a^{-1}\varepsilon(a^{-1}) \in Q$. If $\varepsilon = \mathbb{1}$ then Q is just the positive cone $Q = \{\, a^2 \mid a \in R^* \,\}$. In case $R = \mathbb{R}$ this is $Q = \mathbb{R}_{>0}$. And in case $R = \mathbb{C}$ under the complex conjugation $\varepsilon = \kappa$ we also have $Q = \mathbb{R}_{>0}$.
The reason we need this set is the Gram-Schmidt orthonormalization (4.97). Here we will use some $r(x) \in R^*$ such that $s(x,x) = r(x)\,\varepsilon r(x)$. In both cases $R = \mathbb{R}$ and $R = \mathbb{C}$ (and s is the scalar, resp. the

inner product) we may take $r(x) = \sqrt{\langle x \mid x \rangle}$ to do so. Later on we will take this for the definition of the norm of x and interpret this expression as the length of $x \in \mathbb{C}^n$.

(4.95) Example:

(i) The scalar product $\mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ is a sesqui-linear form on the $\mathbb{R}$-vector-space $\mathbb{R}^n$ [with respect to the identity map on $\mathbb{R}$]. It is positive definite, as for all $x \in \mathbb{R}^n$ with $x \neq 0$ we have $\langle x, x \rangle > 0$ and thereby we have $r \in \mathbb{R}^*$ and $r^2 = \langle x, x \rangle$ for the square root

$$r \;=\; \sqrt{\langle x, x \rangle} \;\in\; \mathbb{R}_{>0}$$

(ii) In fact for any matrix $A \in \mathrm{mat}_n(\mathbb{R})$ with $A = A^*$ the map $b(x \mid y) := \langle Ax, y \rangle$ is a symmetric bilinear form on $\mathbb{R}$ and hence a sesqui-linear form. However b need not be positive definite unless A satisfies further properties. We will later see, that a matrix A whose eigenvalues are all strictly positive will make a positive definite b.

(iii) The inner product $\mathbb{C}^n \times \mathbb{C}^n \to \mathbb{C}$ is a sesqui-linear form on the $\mathbb{C}$-vector-space $\mathbb{C}^n$ [with respect to the complex conjugation κ on $\mathbb{C}$]. It is positive definite for the same reason as in (i). The scalar product on $\mathbb{C}^n$ is not positive definite, as $\langle z, z \rangle = 0$ does not imply $z = 0$.

(iv) As in (ii) the map $s(x \mid y) := \langle Ax \mid y \rangle$ for some matrix $A \in \mathrm{mat}_n(\mathbb{C})$ that satisfies satisfies $A = \overline{A}$ is a sesqui-linear form with respect to the complex conjugation κ. As in (ii) we have to imposes further restrictions on A to guarantee that s is positive definite.

(v) Item (iii) can be generalized: If $b : R^n \times R^n \to R$ is a symmetric bilinear form and $\varepsilon \in \mathrm{rend}(R)$ is some endomorphism of the ring R with $\varepsilon^2 = \mathbb{1}_R$ (in particular ε is bijective), then we let $\varepsilon(x) := (\varepsilon(x_1), \ldots, \varepsilon(x_n))$ for any $x = (x_1, \ldots, x_n) \in R^n$ and $s(x \mid y) := b(x, \varepsilon(y))$. Thereby s is a sesqui-linear form, with respect to ε.

(vi) If V is a finite-dimensional $\mathbb{R}$-vector-space, then V admits a positive definite, symmetric, bilinear form b: Just choose a basis $\{ v_1, \ldots, v_n \}$ of V. Then there is a isomorphism of vector-spaces

$$\Phi \;:\; \mathbb{R}^n \to V \;:\; (x_1, \ldots, x_n) \mapsto \sum_{k=1}^{n} x_k v_k$$

And thereby we can define the bilinear form $b : V \times V \to \mathbb{R}$ (that depends on the choice of the basis) by pulling back the scalar product from $\mathbb{R}^n$, that is for $u, v \in V$ we let

$$b(u \mid v) \;:=\; \langle \Phi^{-1}(u), \Phi^{-1}(u) \rangle$$

(vii) Likewise if V is a finite-dimensional $\mathbb{C}$-vector-space, then V admits a positive definite, sesqui-linear form s with respect to κ: As in (vi) we choose a basis of V and take $\Phi : \mathbb{C}^n \xrightarrow{\sim} V$. Then for $u, v \in V$ we let

$$s(u \mid v) \;:=\; \langle \Phi^{-1}(u) \mid \Phi^{-1}(v) \rangle$$

(viii) Let $M := \mathrm{mat}_{m,n}(R)$ and for $A, B \in M$ define $b(A \mid B) := \mathrm{tr}(AB^*)$, then b is a symmetric bilinear form. Specifically for $R = \mathbb{C}$ we may take $s(A \mid B) := \mathrm{tr}(A\overline{B})$, then s is a sesqui-linear form on M

with respect to κ. In fact $b(A \mid B)$ is given by

$$b(A \mid B) \;:=\; \mathrm{tr}(AB^*) \;=\; \sum_{i=1}^{m} \langle \mathrm{row}_i(A),\, \mathrm{row}_i(B) \rangle$$

(ix) Let $M := C([a,b], \mathbb{R})$ be the $\mathbb{R}$-vector space of continuous functions of the form $f : [a,b] \to \mathbb{R}$. Then we obtain a symmetric bilinear form on M by letting

$$b(f \mid g) \;:=\; \int_a^b f(x) \cdot g(x)\, dx$$

Likewise for the $\mathbb{C}$-vector-space $M = C([a,b], \mathbb{C})$ of continuos functions of the form $f : [a,b] \to \mathbb{C}$, then in complete analogy, we obtain a sesqui-linear form on M, by letting

$$s(f \mid g) \;:=\; \int_a^b f(x) \cdot \overline{g(x)}\, dx$$

(4.96) Example:
For any commutative ring $(R, +, \cdot)$ the Euclidean basis $\{ e_1, \ldots, e_n \}$ is an ONB of R^n with respect to the scalar product on R^n. In $\mathbb{C}^n$ the Euclidean basis $\{ e_1, \ldots, e_n \}$ also is an ONB of $\mathbb{C}^n$ with respect to the inner product on $\mathbb{C}^n$. However an ONB need not be unique: For example in the case $R = \mathbb{R}$ or $R = \mathbb{C}$ and $n = 2$ there is another ONB of R^2, namely

$$\left\{ \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 1 \end{pmatrix},\; \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ -1 \end{pmatrix} \right\}$$

(4.97) Theorem: (viz. 938)
Let $(R, +, \cdot)$ be a commutative ring with a fixed endomorphism $\varepsilon \in \mathrm{rend}(R)$. Also let s be a sesqui-linear form with respect to ε on the R-module M. Then

(i) A subset $\{ m_i \mid i \in I \} \subseteq M$ already is linear independent, if it is an *ortho-normal system* of M with respect to s, that is if it satisfies

$$\forall\, i, j \in I \;:\; s(m_i \mid m_j) \;=\; \delta_{i,j}$$

(ii) If $\{ m_i \mid i \in I \}$ is an ONB with respect to s then for any $x \in M$ the coefficients of the basis representation of x are given by $s(x \mid m_i)$ and therefore

$$x \;=\; \sum_{i \in I} s(x \mid m_i)\, m_i$$

(iii) If M is a free, finitely generated R-module and s is positive definite, then M has an ONB $\{ g_1, \ldots, g_n \}$ with respect to s. And this can be gained in the following way:

Gram-Schmidt-Orthonormalisation: If $\{ m_1, \ldots, m_n \}$ is a basis of M, then the following algorithm generates generates the ONB $\{ g_1, \ldots, g_n \}$ out of $\{ m_1, \ldots, m_n \}$: For any $0 \neq x \in M$ there is some $r(x) \in R^*$ with $r(x) \cdot \varepsilon(r(x)) = s(x \mid x)$. Now define

$$N(x) \;:=\; \begin{cases} r(x)^{-1} x \text{ if } x \neq 0 \\ 0 \text{ if } x = 0 \end{cases} \;\in\; M$$

and start with $g_1 := N(m_1)$. For $k \in 2 \ldots n$ suppose we have already constructed $\{ g_1, \ldots, g_{k-1} \}$ then g_k is taken to be following element of M

$$g_k \;:=\; N\left(m_k - \sum_{i=1}^{k-1} s(m_k \mid g_i)\, g_i \right)$$

Then $\{ g_1, \ldots, g_n \}$ is an ONB of M with respect to s and for any $k \in 1 \ldots n$ this basis also satisfies

$$\mathrm{Lh}\{ g_1, \ldots, g_k \} \;=\; \mathrm{Lh}\{ m_1, \ldots, m_k \}$$

(4.98) Corollary: (viz. 939)
Let $(F, +, \cdot)$ be a field, $\varepsilon \in \mathrm{rend}(F)$ be an endomorphism of F, V be a finite-dimensional F-vector-space and s be a positive definite sesqui-linear form on V (with respect to ε). Recall the definition of the orthogonal complement of some subspace $U \leq_{\mathrm{v}} V$ of V

$$U^\perp \;=\; \{ x \in V \mid \forall\, u \in U \,:\, s(x \mid u) = 0 \} \;=\; \bigcap_{u \in U} \mathrm{kn}\,(x \mapsto s(x \mid u))$$

Then $U^\perp \leq_{\mathrm{v}} V$ is another subspace and V is the inner direct sum of U and $U^\perp$. Finally the orthogonal complement of $U^\perp$ is U again. Together these are the following two properties

$$\begin{aligned} V &= U \oplus U^\perp \\ (U^\perp)^\perp &= U \end{aligned}$$

And thereby V has an ONB $\{ g_1, \ldots, g_r, \ldots, g_n \} \subseteq V$ with respect to s that splits V into the subspaces U and $U^\perp$. That is, there is some $r \in 0 \ldots n$ such that we get

$$\begin{aligned} U &= \mathrm{Lh}\{ g_1, \ldots, g_r \} \\ U^\perp &= \mathrm{Lh}\{ g_{r+1}, \ldots, g_n \} \end{aligned}$$

(4.99) Definition:
Let $(R, +, \cdot)$ be a commutative ring and M, N be R-modules. Then we introduce the following notions:

(i) The set of all linear forms $f : M \to R$ [which is an R-module itself, according to (3.71.(v))] is called the **dual space** of M and we denote it by

$$M' \;:=\; \mathrm{mhom}_R(M, R)$$

(ii) As M' is an R-module again, we may define the **bidual** M'' of M to be the dual space of the dual

space of M: $M'' := (M')' = \mathrm{mhom}_R(M', R)$. Thus we obtain the **natural map**

$$\beta \ : \ M \to M'' \ : \ x \mapsto \big(f \mapsto f(x)\big)$$

that is $\beta(x)(f) = f(x) \in R$. Clearly this is a homomorphism of R-modules again and M is said to be **reflexive**, iff this β even is an isomorphism.

(iii) A map of the form $\delta : M \times N \to R$ is said to be a **duality** of M and N, iff it is linear in the first argument and additive in the second argument. That is for any $u, v \in M$, $x, y \in N$ and $a \in R$

(1) $\delta(au, x) \ = \ a \cdot \delta(u, x)$

(2) $\delta(u + v, x) \ = \ \delta(u, x) + \delta(v, x)$

(3) $\delta(u, x + y) \ = \ \delta(u, x) + \delta(u, y)$

Note that the properties (1) and (2) just state that for any $x \in N$ the map $u \mapsto \delta(u, x)$ is linear and thereby we obtain a natural map

$$N \to M' \ : \ x \mapsto \delta_x \quad \text{where} \quad \delta_x(u) = \delta(u, x)$$

(iv) The ordered pair (M, N) is said to be a **dual pair** of modules **under the duality** δ iff it satisfies the following three properties

(1) $\delta : M \times N \to R$ is a duality

(2) $\forall\, u \in M \ : \ \big(\forall\, x \in N : \delta(u, x) = 0\big) \implies u = 0$

(3) $\forall\, x \in N \ : \ \big(\forall\, u \in M : \delta(u, x) = 0\big) \implies x = 0$

(v) Let M_1, M_2, N_1 and N_2 be R-modules and let $\varphi_1 : M_1 \to N_1$ and $\varphi_2 : N_2 \to M_2$ be R-linear maps. If also (M_1, M_2) is a dual pair under δ_M and (N_1, N_2) is a dual pair under δ_N, then we say that φ_2 is **conjugate** or **adjoint** to φ_1 iff for any $u \in M_1$ and any $y \in N_2$

$$\delta_M\big(u, \varphi_2(y)\big) \ = \ \delta_N\big(\varphi_1(u), y\big)$$

In this case (if it exists) φ_2 is uniquely determined by φ_1 and we therefore write $\varphi_1' := \varphi_2$ for it.

Prob Suppose both $\varphi_2 : N_2 \to M_2$ and $\overline{\varphi}_2 : N_2 \to M_2$ are adjoint maps of φ_1. In particular we have $\delta_M(u, \varphi_2(y)) = \delta_M(u, \overline{\varphi}_2(y))$ for any $u \in M$ and any $y \in N_2$. But as (M_1, M_2) is a dual pair under δ_M we may subtract to find $\delta_M(u, \varphi_2(y) - \overline{\varphi}_2(y)) = 0$, As this is true for any $u \in M_1$ we get $\varphi_2(y) - \overline{\varphi}_2(y) = 0$. This again is $\varphi_2(y) = \overline{\varphi}_2(y)$ for any $y \in N_2$ such that $\varphi_2 = \overline{\varphi}_2$ is unique.

(4.100) Remark:

(i) By definition the second argument $N \to M' : u \mapsto \delta(u,x)$ of a duality $\delta : M \times N \to R$ is a homomorphism from the additive group $(M,+)$ to the additive group $(R,+)$. In particular we have

(4) $\forall\, u \in M \;:\; \delta(u,0) = 0$

(5) $\forall\, u \in M\, \forall\, x \in N \;:\; \delta(u,-x) = -\delta(u,x)$

Prob As $\delta(u,0) = \delta(u,0+0) = \delta(u,0) + \delta(u,0)$ we find $\delta(u,0) = 0$ by subtracting $\delta(u,0)$ once. And thereby $0 = \delta(u,0) = \delta(u,x-x) = \delta(u,x) + \delta(u,-x)$ such that $\delta(u,-x) = -\delta(u,x)$, as well.

(ii) If $b : M \times N \to R$ is a bilinear map, then b already is a duality of M and N. Likewise if $s : M \times M \to R$ is a sesqui-linear form with respect to some endomorphism $\varepsilon \in \mathrm{rend}(R)$, then s is a duality of M with itself. In particular

$$\begin{aligned} R^n \times R^n \to R &\;:\; (x,y) \mapsto \langle x,y\rangle \\ \mathbb{C}^n \times \mathbb{C}^n \to \mathbb{C} &\;:\; (w,z) \mapsto \langle w \mid z\rangle \end{aligned}$$

are dualities of R^n resp. of $\mathbb{C}^n$ with itself. Thereby (R^n, R^n) even is a dual pair under the scalar product and $(\mathbb{C}^n, \mathbb{C}^n)$ also is a dual pair under the inner product.

Prob Everything is trivial, but the claim of the dual pairs: For this we pick up the Euclidean basis $\{ e_1, \ldots, e_n \} \subseteq R^n$. Then for any $u = (u_1, \ldots, u_n) \in R^n$ we have $u_k = \langle u, e_k\rangle$. Thus we have property (2) of a dual pair. Likewise property (3) follows from $x_k = \langle e_k, x\rangle$ for any $x = (x_1, \ldots, x_n) \in R^n$. The proof for $\mathbb{C}^n$ is exactly the same.

(iii) For any R-module M we find a bilinear map (in particular a duality) of M and its dual space M' by virtue of

$$M \times M' \to R \;:\; (x,f) \mapsto f(x)$$

Prob As $f \in M'$ is linear we get $(ax+y, f) \mapsto f(ax+y) = af(x) + f(y)$ which is the linearity in the first argument. And as M' is equipped with point-wise operations we also get $(x, af+g) \mapsto (af+g)(x) = af(x) + g(x)$ which is the linearity in the second argument.

(iv) (■) The following example is taken from integration theory, it is not needed four our purposes: Let (X, Σ, μ) be a *measure space*, that is X is a non-empty set, Σ a σ-algebra on X and μ a measure of Σ. For any $1 \leq p \in \mathbb{R}$ there is the $\mathbb{R}$-vector-space of *p-times integrable* functions

$$L^p(X,\mu) \;:=\; \{ f : X \to \mathbb{R} \mid |f|^p \text{ is Lebesgue-integrable} \}$$

Now let $1 \leq p, q \in \mathbb{R}$ with $1/p + 1/q = 1$, then by the Hölder-inequality (e.g. refer to Bauer, Maß- und Integrationstheorie, 14.6) we obtain the dual pair $(L^p(X,\mu), L^q(X,\mu))$ under the duality

$$L^p(X,\mu) \times L^q(X,\mu) \to \mathbb{R} \;:\; (f,g) \mapsto \int_X |f(x) \cdot g(x)|\, d\mu(x)$$

(4.101) Proposition: (viz. 941)
Let $(R, +, \cdot)$ be a commutative ring and M and N be R-modules. Then the following statements are true:

(i) If $\{ m_1, \ldots, m_n \}$ is an R-base of M, then $\{ m'_1, \ldots, m'_n \}$ is an R-base of the dual space M' (called the **dual base** of $\{ m_1, \ldots, m_n \}$), where for any $j \in 1 \ldots n$ the element $m'_j \in M'$ is defined by

$$m'_j \ : \ M \to R \ : \ \sum_{i=1}^{n} a_i \, m_i \mapsto a_j$$

Nota that this statement can not be generalized to infinite dimensions. Even over a field the dual space V' over an infinite-dimensional vector-space V will exceed V in dimension, as the m'_j form a linearly independent set, that does not generate V' however.

(ii) Let $\{ m_1, \ldots, m_n \} \subseteq M$ be a basis of M and $\{ m'_1, \ldots, m'_n \} \subseteq M'$ be its dual basis. Likewise let $\{ m''_1, \ldots, m''_n \} \subseteq M''$ be the dual basis of $\{ m'_1, \ldots, m'_n \}$, then we find that (for any $k \in 1 \ldots n$)

$$\beta(m_k) \ = \ m''_k$$

(iii) If M is a free R-module then the natural map $\beta : M \to M''$ is injective. If M is free and finitely generated, then β even is bijective. In particular any free, finitely generated module is reflexive.

(iv) For any R-module M the following three statements are equivalent

(a) the natural map β is injective

(b) (M, M') is a dual pair under $\delta(x, f) := f(x)$

(c) $\forall\, x \in M \ : \ \big(\forall\, f \in M' : f(x) = 0\big) \implies x = 0$

(v) Let $\delta : M \times N \to R$ be any map and for $x \in N$ denote $\delta_x : M \to R$ defined by $\delta_x(u) := \delta(u, x)$ again. Also let $\mathrm{im}(\delta) := \{ \delta_x \mid x \in N \}$ then (M, N) is a dual pair under δ if and only if

(1) $\delta : M \times N \to R$ is a duality

(2') $\forall\, u \in M \ : \ \big(\forall\, f \in \mathrm{im}(\delta) : f(u) = 0\big) \implies u = 0$

(3') the natural map $N \to M' : x \mapsto \delta_x$ is injective

(vi) Fix an automorphism $\varepsilon \in \mathrm{aut}(R)$ of the ring R and $s : M \times M \to R$ a positive definite sesqui-linear form on M with respect to ε. Assume that M is free and finitely generated then the following map

$$S \ : \ M \to M' \ : \ y \mapsto \big(x \mapsto s(x \mid y)\big)$$

not only is well-defined and ε-linear, but also is bijective. Recall that ε-linear means that for any $y, z \in M$ and any $a \in R$ we get

$$\begin{aligned} S(ay) &= \varepsilon(a) S(y) \\ S(y + z) &= S(y) + S(z) \end{aligned}$$

Remark: Note that S is well-defined and ε-linear for any sesqui-linear form S and any module M. If s is positive definite, then S already is injective. Also note that if R is noetherian and ε is surjective, then ε already is bijective, as well, according to (3.82.(i)).

(4.102) Remark:
With this knowledge in mind let us return to the definition of the adjoint of a homomorphism of R-modules:

(i) Recall the notation of (4.99.(v)) and let us present a diagram of what it means that $\varphi_2 : N_2 \to M_2$ is the adjoint of some module homomorphism $\varphi_1 : M_1 \to N_2$

$$\begin{array}{ccccccc} \delta_M & : & M_1 & \times & M_2 & \to & R \\ & & \downarrow \varphi_1 & & \uparrow \varphi_2 & & \\ \delta_N & : & N_1 & \times & N_2 & \to & R \end{array}$$

(ii) This definition is usually applied to the following case: If M is a free R-module then the natural map $\beta : M \to M''$ is injective and hence (M, M') is a dual pair under $\delta(x, f) := f(x)$ - according to (4.101) again. Let us fix this duality, then we get

$$\begin{array}{ccccccccc} M & \times & M' & \to & R & : & (x,f) & \mapsto & f(x) \\ \downarrow \varphi & & \uparrow \varphi' & & & & & & \\ N & \times & N' & \to & R & : & (y,g) & \mapsto & g(y) \end{array}$$

If M and N are free R-modules and $\varphi : M \to N$ is a linear map, then $\varphi' : N' \to M'$ is the adjoint map of φ if and only if

$$\forall\, g \in N' \;:\; g\varphi \;=\; \varphi'(g) \;\in\; M'$$

Prob for any $u \in M$ and $g \in N'$ we have $\beta(\varphi(u), g) = g(\varphi(u)) = g\varphi(u)$ and likewise $\beta(u, \varphi'(g)) = \varphi'(g)(u)$. If φ' is the adjoint of φ then these are equal $g\varphi(u) = \varphi'(g)(u)$ and as $u \in M$ has been arbitrary this is the equality of maps $g\varphi \;=\; \varphi'(g)$.

(iii) If $(R, +, \cdot)$ is a commutative ring and $1 \leq m, n \in \mathbb{N}$ then (R^m, R^m) and (R^n, R^n) are a dual pairs under the respective scalar products. Let now $\varphi : R^n \to R^m$ be given by the matrix $A \in \mathrm{mat}_{m,n}(R)$, that is $\varphi(x) = Ax$ for any $x \in R^n$. Then the adjoint φ' of φ is given to be the transpose matrix A^* of A, as $\langle x, \varphi'(y)\rangle = \langle x, A^*y\rangle = \langle Ax, y\rangle = \langle \varphi(x), y\rangle$ is true for any $x \in R^n$ and $y \in R^m$

$$\varphi' \;:\; R^m \to R^n \;:\; y \mapsto A^*y$$

(iv) Specifically for $R = \mathbb{C}$ we also have the dual pairs $(\mathbb{C}^m, \mathbb{C}^m)$ and $(\mathbb{C}^n, \mathbb{C}^n)$ respective inner products. Again, if $\varphi : \mathbb{C}^n \to \mathbb{C}^m$ is given by the matrix $A \in \mathrm{mat}_{m,n}(R)$, that is $\varphi(x) = Ax$ for any $x \in \mathbb{C}^n$, then the adjoint map φ' of φ is given to be the complex conjugate matrix $\overline{A}$ of A, as $\langle x \mid \varphi'(y)\rangle = \langle x \mid \overline{A}\, y\rangle = \langle Ax \mid y\rangle = \langle \varphi(x) \mid y\rangle$ is true for any $x \in \mathbb{C}^n$ and $y \in \mathbb{C}^m$

$$\varphi' \;:\; \mathbb{C}^m \to \mathbb{C}^n \;:\; y \mapsto \overline{A}\, y$$

(v) Let M is an R-module and consider $b : M \times M \to R$ a bilinear map on M (e.g. the scalar product in case of $M = R^n$). As always there also is the natural map $\beta : M \times M' : (x, f) \mapsto f(x)$. Now, if $P \leq_{\mathsf{m}} M$ is any sub-module of M we would like to compare the orthogonal complements of P with respect to b and to β, these are

$$\begin{aligned} b(P\,|\bot) &= \{\, y \in M \mid \forall\, x \in P : b(x \mid y) = 0 \,\} \\ \beta(P\,|\bot) &= \{\, f \in M' \mid \forall\, x \in P : f(x) = 0 \,\} \end{aligned}$$

Note that $b(P\,|\bot) \leq_{\mathsf{m}} M$ and $\beta(P\,|\bot) \leq_{\mathsf{m}} M'$ so they seem to be completely separate concepts, so far. But according to (4.101.(vi)) b induces a canonical homomorphism of the form

$$b' \,:\, M \xrightarrow{\sim} M' \,:\, y \mapsto \big(x \mapsto b(x \mid y)\big)$$

and for this it is clear, that $b'\big(b(P\,|\bot)\big) \subseteq \beta(P\,|\bot)$. If M is a finitely generated, free R-module then b' even is an isomorphism, and in this case we even get the equality

$$b'\Big(b(P\,|\bot)\Big) = \beta(P\,|\bot)$$

Without b we could still have chosen a basis $\{m_1, \ldots, m_n\}$ of M and this would have induces an isomorphism $M \xrightarrow{\sim} M'$ by linear expansion of $m_k \mapsto m'_k$. However this isomorphism depends on the choice of the basis, which we express by saying that it is *non-canonical*. Given b the isomorphy is induced by b and this is why we call it *canonical*.

(4.103) Corollary: (viz. 944)

(i) Let $(R, +, \cdot)$ be a commutative ring and $1 \leq m,\, n \in \mathbb{N}$. First of all we fix the scalar product $b_n : R^n \times R^n \to R : (x, y) \mapsto \langle x, y \rangle$ as a bilinear form on R^n and respectively b_m on R^m. If now $A \in \mathrm{mat}_{m,n}(R)$ is any $(m \times n)$-matrix over R and $A^* \in \mathrm{mat}_{n,m}(R)$ is its transpose then

$$\begin{aligned} \mathrm{kn}(A) &= \big(\mathrm{im}\,(A^*)\,\big)^{\bot} \\ \mathrm{kn}(A^*) &= \big(\mathrm{im}\,(A)\,\big)^{\bot} \end{aligned}$$

Let $(R, +, \cdot)$ be a commutative ring, $\varepsilon \in \mathrm{aut}(R)$ be an automorphism of R and M and N be a finitely generated, free R-modules. Say $s : M \times M \to R$ and $t : N \times N \to R$ are positive definite sesqui-linear forms (both with respect to ε) and consider $\varphi : M \to N$ a homomorphism of R-modules. Then we get

(ii) Since s is positive definite we have $M^{\bot} = 0$. Likewise, as t is positive definite we have $N^{\bot} = 0$

$$\begin{aligned} M^{\bot} &= \{\, u \in M \mid \forall\, v \in M : s(u \mid v) = 0 \,\} &&= \{0\} \\ N^{\bot} &= \{\, x \in N \mid \forall\, y \in N : t(x \mid y) = 0 \,\} &&= \{0\} \end{aligned}$$

(iii) φ has a (uniquely determined) adjoint homomorphism $\varphi' : N \to M$ of R-modules. And if $\mathcal{M}$ and $\mathcal{N}$ are ordered ONB of M and N respectively and $A = [\varphi]^{\mathcal{N}}_{\mathcal{M}}$ is the matrix representation of φ, then φ' has the matrix representation $[\varphi']^{\mathcal{M}}_{\mathcal{N}} = \varepsilon^{-1}(A^*)$ and satisfies (for any $u,\, v \in M$ and $x,\, y \in N$)

$$t\big(\varphi(u) \mid y\big) = s\big(u \mid \varphi'(y)\big)$$

$$t\big(x \mid \varphi(v)\big) \;=\; s\big(\varphi'(x) \mid v\big)$$

(iv) If φ' is the adjoint homomorphism of φ then we have the following identities for the kernels of φ and φ' respectively

$$\begin{aligned} \mathrm{kn}(\varphi) &= \big(\mathrm{im}\,(\varphi')\,\big)^{\perp} \\ \mathrm{kn}(\varphi') &= \big(\mathrm{im}\,(\varphi)\,\big)^{\perp} \end{aligned}$$

(4.104) Proposition: (viz. 943)
Let $(R,+,\cdot)$ be a commutative ring and $\varepsilon \in \mathrm{aut}(R)$ be an automorphism of R. Also let M a finitely generated, free R-module and $\varphi \in \mathrm{end}(m)$ an endomorphism of M. Finally let $s : M \to M \to R$ be a positive definite sesqui-linear form. If $\mathcal{M}$ is an ordered ONB of M let us denote the matrix representations of φ and φ' by $A := [\varphi]_{\mathcal{M}}$ and $A' := [\varphi']_{\mathcal{M}}$ respectively. Then we define:

(i) If A is the matrix representation of φ in the ordered ONB $\mathcal{M}$ of M, then the matrix representation A' of the adjoint endomorphism φ' in the same basis $\mathcal{M}$ is given to be

$$A' \;=\; \varepsilon^{-1}\big(A^*\big)$$

(ii) φ is said to be **self-adjoint**, iff it satisfies one of the following three equivalent properties

(a) $\varphi' = \varphi$

(b) For any ordered ONB $\mathcal{M}$ of M we get $A^* = \varepsilon(A)$

(c) There is an ordered ONB $\mathcal{M}$ of M such that $A^* = \varepsilon(A)$

(iii) φ is said to be **normal**, iff it satisfies one of the following three equivalent properties

(a) $\varphi'\,\varphi \;=\; \varphi\,\varphi'$

(b) For any ordered ONB $\mathcal{M}$ of M we get $\varepsilon^{-1}(A^*)\,A \;=\; A\,\varepsilon^{-1}(A^*)$

(c) There is an ordered ONB $\mathcal{M}$ of M such that $\varepsilon^{-1}(A^*)\,A \;=\; A\,\varepsilon^{-1}(A^*)$

(4.105) Remark:
If φ in (4.104) is sefl-adjoint, but $\mathcal{M}$ is an ordered basis of M, but *not* an ONB, then A need *not* be ε-symmetric [that is satisfy $A^* = \varepsilon(A)$]. As a counter-example regard $\varepsilon = \mathbb{1}$, $M = \mathbb{R}^2$ and the following endomorphism on M:

$$\varphi \;:\; \mathbb{R}^n \to \mathbb{R}^n \;:\; (x,y) \mapsto \big(x+2y,\, 2x+3y\big)$$

It is clear that φ has the following symmetric matrix representation in the euclidean basis $\mathcal{E} = (e_1, e_2)$ of $\mathbb{R}^2$ and hence is self-adjoint, by property (c) in the definition above

$$[\varphi]_{\varepsilon} \;=\; \begin{pmatrix} 1 & 2 \\ 2 & 3 \end{pmatrix}$$

Take a look at another ordered basis $\mathcal{M} := (m_1, m_2)$ where $m_1 := e_1 = (1,0)$ and $m_2 := (1,1)$. In this ordered basis φ does *not* have a symmetric matrix representation, instead

$$[\varphi]_{\mathcal{M}} \;=\; [\mathbb{1}]^{\mathcal{M}}_{\mathcal{E}}[\varphi]_{\mathcal{E}}[\mathbb{1}]^{\mathcal{E}}_{\mathcal{M}} \;=\; \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 2 \\ 2 & 3 \end{pmatrix}\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \;=\; \begin{pmatrix} -1 & -2 \\ 2 & 5 \end{pmatrix}$$

(4.106) Definition:
Let us append a generalization of the concept of an orthogonal complement introduced in (4.98) in the general setting of modules: Let $(R,+,\cdot)$ and $(S,+,\cdot)$ be any rings, α and $\beta : R \to S$ be fixed homomorphisms of rings and consider the R-modules L, M and the S-module N. Finally let b be a map of the form

$$b \;:\; L \times M \;\to\; N$$

that is α-linear in the first and β-linear in the second argument. That is for any $u, v \in L$, any $x, y \in M$ and any $a \in R$ we assume the following identities

$$\begin{aligned} b(u+v \mid x) &= b(u \mid x) + b(v \mid x) \\ b(u \mid x+y) &= b(u \mid x) + b(u \mid y) \\ b(au \mid x) &= \alpha(a)\, b(u \mid x) \\ b(u \mid ax) &= \beta(a)\, b(u \mid x) \end{aligned}$$

That is: If $S = R$ and $\alpha = \beta = \mathbb{1}$, then b is bilinear. For any subsets $P \subseteq L$ and $Q \subseteq M$ we define the **orthogonal complement** of P resp. of Q with respect to b, to be the following sub-modules of M resp. of L

$$Q^{\perp} \;:=\; \{\, u \in L \mid \forall\, q \in Q \,:\, b(u \mid q) = 0 \,\} \;=\; \bigcap_{q \in Q} \mathrm{kn}\big(u \mapsto b(u \mid q)\big)$$

$$P^{\top} \;:=\; \{\, x \in M \mid \forall\, p \in P \,:\, b(p \mid x) = 0 \,\} \;=\; \bigcap_{p \in P} \mathrm{kn}\big(x \mapsto b(p \mid x)\big)$$

In case of ambiguity we also write $b(P \mid \perp) := P^{\top}$ and $b(\perp \mid Q) := Q^{\perp}$ to emphasize the α-β-linear map used in the construction of these sets. Now b is said to be **non-degenerate** iff both $L^{\perp} = 0$ and $M^{\perp} = 0$. That is iff $b(u \mid x) = 0$ for any $x \in M$ is true only for $u = 0$ and likewise $b(u \mid x) = 0$ for any $u \in L$ is true only for $x = 0$. Formally, iff for any $u \in L$ and $x \in M$ we have

$$\begin{aligned} \Big(\forall\, x \in M : b(u \mid x) = 0\Big) \quad &\Longrightarrow \quad u \;=\; 0 \\ \Big(\forall\, u \in L : b(u \mid x) = 0\Big) \quad &\Longrightarrow \quad x \;=\; 0 \end{aligned}$$

A stronger version of this notion is the following: b is said to be **integral**, iff $b(x \mid y) = 0$ implies that $x = 0$ or $y = 0$. That is, iff for any $u \in L$ and $x \in M$ we have the implication

$$b(u \mid x) \;=\; 0 \quad\Longrightarrow\quad u \;=\; 0 \;\text{ or }\; x \;=\; 0$$

(4.107) Proposition: (viz. 940)
As in definition (4.106) above, let $b : L \times M \to N$ be a α-β-linear map from the R-modules L and M to the S-module N. Then we get:

(i) The maps $P \mapsto P^\top$ and $Q \mapsto Q^\perp$ are a Galois connection [refer to (0.22)] between the sets of sub-modules $\mathrm{Subm}(L)$ and $\mathrm{Subm}(M)$ partially ordered under the inclusion $\subseteq$ of sets:

$$\begin{array}{rcl} \mathrm{Subm}(M) & \to & \mathrm{Subm}(M') \\ P & \mapsto & P^\top \\ F^\perp & \hookleftarrow & F \end{array}$$

(ii) We obtain another well-defined map $\overline{b}$, that is non-degenerate, α-linear in the first and β-linear in the second argument, by virtue of

$$\overline{b} \;:\; {}^{L}\big/_{M^\perp} \times {}^{M}\big/_{L^\top} \;\to\; N \;:\; \left(x + M^\perp, y + L^\top\right) \;\mapsto\; b(x,y)$$

(iii) If $(P_i) \subseteq \mathrm{Subm}(L)$ (where $i \in I \neq \emptyset$) and $(Q_j) \subseteq \mathrm{Subm}(M)$ (where $j \in J \neq \emptyset$) and are arbitrary families of sub-modules of L and M respectively, then we get

$$\begin{aligned} \left(\sum_{i\in I} P_i\right)^\top &= \bigcap_{i\in I} P_i^\top \\ \left(\sum_{j\in J} Q_j\right)^\perp &= \bigcap_{j\in J} Q_j^\perp \end{aligned}$$

(iv) Suppose that $\alpha = \beta$ and that b is *integral*, then all elements $x \in L$ and $y \in M$ share the same annihilator and if $x \neq 0$ this is a prime ideal in R. That is we get

$$x \neq 0 \;\text{ and }\; y \neq 0 \quad\Longrightarrow\quad \mathrm{ann}(x) \;=\; \mathrm{ann}(y) \;\in\; \mathrm{Spec}(R)$$

(4.108) Remark:
The standard case of the α-β-linear map b in definition (4.106) is the canonical bilinear map of an R-module M and its dual space M' given by

$$\delta \;:\; M \times M' \to R \;:\; (x,f) \mapsto f(x)$$

Let us repeat the definition of the orthogonal complements of sub-modules $P \leq_{\mathsf{m}} M$ and $F \leq_{\mathsf{m}} M'$ in this case respectively

$$\begin{aligned} P^\top \;=\; \delta(P \mid \perp) \;&:=\; \left\{ f \in M' \mid \forall\, x \in P \,:\, f(x) = 0 \right\} \\ F^\perp \;=\; \delta(\perp \mid F) \;&:=\; \left\{ x \in M \mid \forall\, f \in F \,:\, f(x) = 0 \right\} \end{aligned}$$

This is what inspired our notation: If we consider M' to be one level above M, then $\top$ raises P one level to $P^\top \subseteq M'$. Likewise $\bot$ lowers F one level $F^\bot \subseteq M$. This of course can be iterated, such that $P^{\top\top} \subseteq M''$ for example. However $\beta : M \to M''$ allows to pull back $P^{\top\top}$ onto the level of M.

In this general setting let us consider the following example: The $\mathbb{Z}$-module $M = \mathbb{Z}^3$ is free and finitely generated with basis $\{ e_1, e_2, e_3 \}$. The dual module M' then features the dual basis $\{ e'_1, e'_2, e'_3 \}$. We take a look at its sub-module $P = 3\mathbb{Z} \oplus \mathbb{Z} \oplus 0 = \mathsf{Lh}\{ 3e_1, e_2 \} \leq_\mathsf{m} M$. Thus if we consider any $x = (3a, b, 0) \in P$ and any $f = ue'_1 + ve'_2 + we'_3 \in M'$ then $f(x) = 3au + bv$. In order to have $f \in P^\bot$ we need $f(x) = 0$ for *any* $a, b \in \mathbb{Z}$ and in particular $3u = 0$ and $v = 0$. As $\mathbb{Z}$ is an integral domain this implies $u = 0$ such that $f \in \mathbb{Z}e'_3$. Hence we see

$$\big(\mathbb{Z}\,3e_1 + \mathbb{Z}\,e_2\big)^\top \;=\; \mathbb{Z}\,e'_3$$

Likewise it is clear, that $(\mathbb{Z}e'_3)^\bot = \mathbb{Z}e_1 + \mathbb{Z}e_2$ which is a sub-module of M strictly containing P. Thus - even over a PID - not every sub-module of M satisfies $(P^\top)^\bot = P$ and hence there are sub-modules (like our P here) that are *no* orthogonal complement of some $F \leq_\mathsf{m} M'$.

$$\mathbb{Z}\,3e_1 + \mathbb{Z}\,e_2 \;\subset\; \big(\mathbb{Z}\,3e_1 + \mathbb{Z}\,e_2\big)^{\top\bot}$$

The reason behind this is that $3\mathbb{Z}$ is not complemented in $\mathbb{Z}$ and hence P is not complemented in M. In turn the Galois connection will only be bijective on the set of complemented sub-modules of M, not for all sub-modules.

(4.109) Theorem: (viz. 947)
Let $(R, +, \cdot)$ be a commutative ring and M a finitely generated, free R-module where we fix the bilinear map $M \times M' \to R : (x, f) \mapsto f(x)$. Finally let $P \leq_\mathsf{m} M$ be any sub-module of M, then we get the following statements:

(i) If R is an integral domain and $\{ m_1, \ldots, m_n \}$ is a basis of M such that $\{ a_1 m_1, \ldots, a_r m_r \}$ is a basis of P where $r \in \mathbb{N}$ and $a_1, \ldots, a_r \in R$ then we get the following identities

$$\begin{aligned} P^\top &= \mathsf{Lh}\{ m'_{r+1}, \ldots, m'_n \} \\ P^{\top\bot} &= \mathsf{Lh}\{ m_1, \ldots, m_r \} \;=\; \mathsf{Hull}(P) \end{aligned}$$

Nota that in case of a PID R we know by (5.28.(iv)) there always is a basis $\{ m_1, \ldots, m_n \}$ of M and factors $a_1, \ldots, a_r \in R$ such that $\{ a_1 m_1, \ldots, a_r m_r \}$ is a basis of P.

(ii) Let R be a field and M be a finite-dimensional R-vector space. Then there is a basis $\{ m_1, \ldots, m_n \}$ is a basis of M such that $\{ m_1, \ldots, m_r \}$ is a basis of P (for some $r \in 0 \ldots n$) and thereby

$$\begin{aligned} P^\top &= \mathsf{Lh}\{ m'_{r+1}, \ldots, m'_n \} \\ P^{\top\bot} &= \mathsf{Lh}\{ m_1, \ldots, m_r \} \;=\; P \end{aligned}$$

(iii) Let $\beta : M \to M'' : x \mapsto x''$ be the natural map again, that is x'' is the map $x'' : M' \to R : f \mapsto f(x)$ and consider some sub-modules $P \leq_{\mathsf{m}} M$ and $F \leq_{\mathsf{m}} M'$, then we get the identities

$$\begin{aligned} \beta(P)^{\perp} &= P^{\top} \leq_{\mathsf{m}} M' \\ \beta\left(F^{\perp}\right) &= F^{\top} \leq_{\mathsf{m}} M'' \end{aligned}$$

(iv) If R even is a PID, then the following statements on P are equivalent:

(a) M admits a basis $\{ m_1, \ldots, m_n \}$ such that there is some $r \in \mathbb{N}$ such that the subset $\{ m_1, \ldots, m_r \}$ is a basis of P.

(b) P is *complemented*, that is there is another sub-module $Q \leq_{\mathsf{m}} M$ such that M is the inner direct sum of P and Q

$$M = P \oplus Q$$

(c) There is some sub-module $F \leq_{\mathsf{m}} M'$ of the dual space of M, such that P is the orthogonal complement of F, that is

$$P = F^{\perp}$$

(d) $P = \mathrm{Hull}(P)$

(e) $P = P^{\top\perp}$

(v) If R is a PID again then the Galois connection of (4.107) interlocks the complemented sub-modules of M and M'. That is, if we denote the set of complemented sub-modules of M by

$$\mathrm{Subc}(M) := \{ P \leq_{\mathsf{m}} M \mid \exists Q \leq_{\mathsf{m}} M : M = P \oplus Q \}$$

then going to orthogonal complements yields a bijection between the sets of complemented sub-modules of M and M' respectively. Formally

$$\begin{array}{rcl} \mathrm{Subc}(M) & \longleftrightarrow & \mathrm{Subc}(M') \\ P & \mapsto & P^{\top} \\ F^{\perp} & \hookleftarrow & F \end{array}$$

(4.110) Proposition: (viz. 946)
Let $(R, +, \cdot)$ be a commutative ring M and N be R-modules and consider the following canonical maps concerning the direct sum $M \oplus N$

$$\begin{aligned} \iota_M &: M \hookrightarrow M \oplus N : & x &\mapsto (x, 0) \\ \iota_N &: M \hookrightarrow M \oplus N : & x &\mapsto (x, 0) \\ \pi_M &: M \oplus N \twoheadrightarrow M : & (x, y) &\mapsto x \\ \pi_N &: M \oplus N \twoheadrightarrow N : & (x, y) &\mapsto y \end{aligned}$$

Then we obtain the following isomorphy of the dual space of $M \oplus N$ [note that $f\pi_M + g\pi_N$ is defined by $(f\pi_M + g\pi_N)(x,y) = f(x) + g(y)$]

$$\begin{array}{rcl} (M \oplus N)' & \xrightarrow{\sim} & M' \oplus N' \\ h & \mapsto & (h\iota_M, h\iota_N) \\ f\pi_M + g\pi_N & \leftarrow\!\shortmid & (f,g) \end{array}$$

Likewise we obtain the following isomorphy of the bidual space of $M \oplus N$

$$\begin{array}{rcl} (M \oplus N)'' & \xrightarrow{\sim} & M'' \oplus N'' \\ \omega & \mapsto & \big(f \mapsto \omega(f\pi_M),\, g \mapsto \omega(g\pi_N)\big) \\ \big(h \mapsto \omega_M(h\iota_M) + \omega_N(h\iota_N)\big) & \leftarrow\!\shortmid & (\omega_M, \omega_N) \end{array}$$

And if we denote the natural maps $\beta_M : M \to M'' : x \mapsto (f \mapsto f(x))$ and $\beta_N : N \to N'' : y \mapsto (g \mapsto g(y))$ respectively and likewise $\beta : M \oplus N \to (M \oplus N)'' : (x,y) \mapsto (h \mapsto h(x,y))$ then we get the following commutative diagram $\Theta\beta = \beta_M \times \beta_N$ where

$$\begin{array}{ccc} M \oplus N & & \\ \downarrow & \searrow & \\ (M \oplus N)'' & \xrightarrow{\sim} & M'' \oplus N'' \end{array}$$

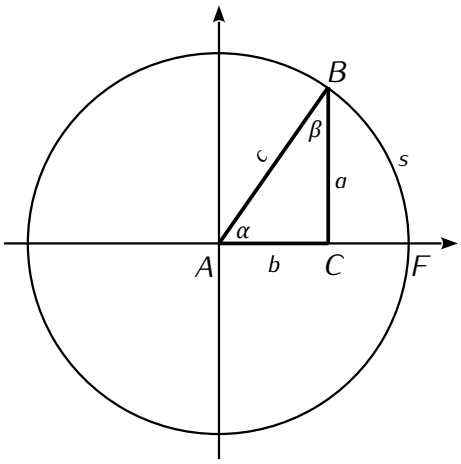
$$\begin{array}{rcl} \beta & : M \oplus N \to (M \oplus N)'' : & (x,y) \mapsto (h \mapsto h(x,y)) \\ \beta_M \times \beta_N & : M \oplus N \to M'' \oplus N'' : & (x,y) \mapsto \big(f \mapsto f(x), g \mapsto g(x)\big) \\ \Theta & : (M \oplus N)'' \xrightarrow{\sim} M'' \oplus N'' : & \big(f \mapsto \omega(f\pi_M),\, g \mapsto \omega(g\pi_N)\big) \end{array}$$

(4.111) Corollary: (viz. 949)

(i) Let $(R,+,\cdot)$ be a commutative ring, M and N be R-modules and denote the natural maps β_M, β_N and β as in (4.110). Also let $\star$ abbreviate any of the words *injective*, *surjective* or *bijective*. Then we find the following equivalence:

$$\beta \text{ is } \star \iff \beta_M \text{ and } \beta_N \text{ are } \star$$

(ii) Let $(R,+,\cdot)$ be a commutative ring and M and N be R-modules then $M \oplus N$ is reflexive if and only if both M and N are reflexive.



(iii) $(\diamondsuit)$ Let again $(R,+,\cdot)$ be a commutative ring, P be any R-module and $\beta : P \to P''$ be the natural map. Then we find two implications

$$\begin{array}{rcl} P \text{ is projective} & \Longrightarrow & \beta \text{ is injective} \\ P \text{ is projective and finitely generated} & \Longrightarrow & P \text{ is reflexive} \end{array}$$

4.8 Vector Geometry

This section will be quite different from the rest of this textbook, in two ways: First of all we will regard the case of the real numbers as the base field for most of the time, second we will apply our theory to elementary geometry where we will appeal to the mathematical intuition and third we use a few ingredients from basic analysis without proving them. We dare to do so, as from a formal point of view none of this is needed in the rest of the textbook.

The most fundamental concept of geometry is that of a triangle. We find a right-angled triangle inside a circle by connecting the points $A = (0,0)$, $B = (b,a)$ and $C = (b,0) \in \mathbb{R}^2$. The right angle is at point C of course.

It probably is the most commonly known fact of mathematics, that the length of the *hypotenuse* (that is the line from A to B) is closely linked to the length of the legs (that are the lines from C to A and C to B respectively). If you never saw the proof of this, look it up - it is really cute:

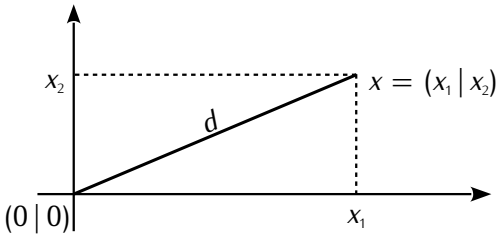
(4.112) Lemma: (viz. 1013) **Pythagorean Theorem**
In a rectangular triangle of the points A, B and C, that has its right angle in C and the length of its sides are: a opposite to A, b opposite to B and c opposite to C, we have the relation

$$c^2 = a^2 + b^2$$

The perimeter of the circle (of radius c is) $2\pi c$ (■) . Thus it stands to reason to define the **angle** α at the point A to be the fraction of the length s of the arc from F to B times the radius c of the circle:

$$\alpha := \frac{s}{c} \in [0, 2\pi]$$

This number is independent of the radius and neatly describes the width of the opening of the triangle at A. It is a measure just how far we have to rotate $F = (c,0)$ to reach B. Using this angle we define following functions

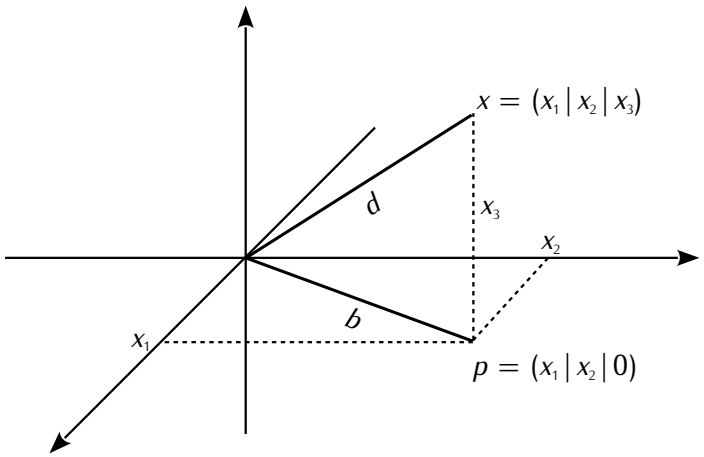


(4.113) Definition:
The **sinus** of the angle α is defined as the ratio of the length of the side opposite to α times the length of the *hypotenuse* of the triangle. The **cosine** of the angle α is defined as the ratio of the length of the side adjacent to α times the length of the hypotenuse:

$$\begin{aligned} \sin(\alpha) &:= \frac{a}{c} \\ \cos(\alpha) &:= \frac{b}{c} \end{aligned}$$

Altogether sinus turns the fraction s/c into the fraction a/c, likewise cosinus that maps $s/c \mapsto b/c$. From the theorem of Pythagoras we then find $\sin(\alpha)^2 + \cos(\alpha)^2 = a^2/c^2 + b^2/c^2 = (a^2+b^2)/c^2 = 1$, which is one of the fundamental properties of these functions:

$$\sin(\alpha)^2 + \cos(\alpha)^2 = 1$$



The theorem of Pythagoras also provides a way of measuring distances in a plane: Given a point $x = (x_1, x_2) \in \mathbb{R}^2$ we find, that this point gives rise to a right-angled triangle by looking at its coordinates:

The distance d from $(0 \mid 0)$ to x [in other words the length of the line from $(0 \mid 0)$ to x] can be computed using the Pythagorean theorem

$$d = \sqrt{x_1^2 + x_2^2}$$

We will now generalize this to higher dimensions: Let us take a look at a point $x = (x_1, x_2, x_3) \in \mathbb{R}^3$ in space. We can still illustrate this:

In order to compute the distance d of x from the origin 0 we use the projection $p = (x_1, x_2, 0)$ of x to the level plane. It has distance b from the origin 0. But then another right-angled triangle emerges, having the side lengths b, x_3 and d, where d is the distance of x from 0. Thus we can compute d

$$\begin{aligned} b^2 &= x_1^2 + x_2^2 \\ d^2 &= b^2 + x_3^2 \;=\; x_1^2 + x_2^2 + x_3^2 \end{aligned}$$

So generally in n dimensions we expect $d^2 = x_1^2 + \cdots + x_n^2$. This even is true for $n = 1$, where $\sqrt{x_1^2} = |x_1|$ is just the absolute value of x_1 that measures the distance of x_1 to 0. Therefore we define:

(4.114) Definition:
If $1 \leq n \in \mathbb{N}$ and $x = (x_1, x_2, \ldots, x_n) \in \mathbb{R}^n$ is a vector (that is a point in n-dimensional space), then we define the **norm** of x by

$$\|x\| \;:=\; \sqrt{x_1^2 + x_2^2 + \cdots + x_n^2}$$

Likewise for $z = (z_1, z_2, \ldots, z_n) \in \mathbb{C}^n$ we define the **norm** of z to be the norm of the absolute values $(|z_1|, |z_2|, \ldots, |z_n|) \in \mathbb{R}^n$

$$\|z\| \;:=\; \sqrt{|z_1|^2 + |z_2|^2 + \cdots + |z_n|^2}$$

And if $S \subseteq \mathbb{F}^n$ is a subset of n-dimensional space, where $\mathbb{F} \in \{\, \mathbb{R}, \mathbb{C} \,\}$ and $x \in \mathbb{F}^n$ is a point, then $p \in S$ is said to be an **orthogonal projection** of x on S, iff it is a point of least distance in S from x, that is iff

$$\forall\, s \in S \quad \text{we get} \quad \|x - p\| \leq \|x - s\|$$

(4.115) Example:
In the light of the Pythagorean theorem we have to interpret the set of solutions $x = (x_1, x_2) \in \mathbb{R}^2$ of the following equation as a circle or radius $r \geq 0$ around the center $c = (c_1, c_2) \in \mathbb{R}^2$ in the plane $\mathbb{R}^2$

$$(x_1 - c_1)^2 + (x_2 - c_2)^2 \;=\; r^2$$

Likewise in three dimensions: We have to interpret the set of solutions $x = (x_1, x_2, x_3) \in \mathbb{R}^3$ of the following equation as a sphere or radius $r \geq 0$ around the center $c = (c_1, c_2, c_3) \in \mathbb{R}^3$ in the space $\mathbb{R}^3$

$$(x_1 - c_1)^2 + (x_2 - c_2)^2 + (x_3 - c_3)^2 \;=\; r^2$$

It is an interesting observation that geometric objects appear as sets of solutions of certain equations. This is the staging area of differential geometry (if we allow differentiable functions in the equation) and algebraic geometry (if we allow polynomial equations in the equation).
The points that are closer to c, than the radius r form a circle or ball of radius r respectively. That is we have to interpret the set of solutions x of the following inequalities as circle or ball of radius r around the center c respectively:

$$\begin{aligned} (x_1 - c_1)^2 + (x_2 - c_2)^2 &\leq r^2 \\ (x_1 - c_1)^2 + (x_2 - c_2)^2 + (x_3 - c_3)^2 &\leq r^2 \end{aligned}$$

The field of convex geometry is dedicated to studying sets of solutions of linear inequalities. Linear Optimization is the theory of finding the minimum of a linear function over such a set. Generalizing these interpretations we define the $(n-1)$-dimensional **sphere** and n-dimensional **(closed) ball** of radius $r \geq 0$ arund the center $c \in \mathbb{R}^n$ to be the respective set

$$\begin{aligned} S_r(c) &:= \{ x \in \mathbb{R}^n \mid \|x - c\| = r \} \\ B_r(c) &:= \{ x \in \mathbb{R}^n \mid \|x - c\| \leq r \} \end{aligned}$$

(4.116) Definition:
Let $(R, +, \cdot)$ be a commutative ring and M be an R-module. A non-empty subset $S \subseteq M$ is called an **affine space** in M iff it satisfies one of the two following equivalent properties

(a) $\exists\, p \in S$ such that $S - p \leq_{\mathsf{m}} M$ is a sub-module of M

(b) $\forall\, s \in S$ the subset $S - s \leq_{\mathsf{m}} M$ is a sub-module of M

And in this case the sub-modules $S - p = S - s$ are equal for any two $p, s \in S$. Thus if the sub-module $S - s$ is free [e.g. if R is a PID and M is a free, finitely generated R-module] we may define the **dimension** of S to be the dimension of the shifted sub-module $S - s$, formally

$$\dim(S) := \dim(S - s) \text{ for an arbitrary } s \in S$$

Prob We will first show that (a) implies $S - s = S - t$ for any $s, t \in S$. By assumption $P := S - p \leq_{\mathsf{m}} M$ is a sub-module. And if $s \in S$ then clearly $d := s - p \in P$. Therefore $-d + P = P$. But hereby

$$P = -d + P = -(s - p) + (S - p) = -s + p + S - p = S - s$$

Thus we have $S - s = -d + P = P = S - p$ for any $s \in S$. In particular $S - t = P = S - s$ for any two $s, t \in S$. Now the implication (a) $\implies$ (b) is easy: Since $S - p$ is a sub-module of M and we also know that $S - s = S - p \leq_{\mathsf{m}} M$ is the same set, clearly $S - s \leq_{\mathsf{m}} M$ is a sub-module, too. The converse implication (b) $\implies$ (a) is trivial, as S is non-empty.

(4.117) Example:

(i) If $P \leq_{\mathsf{m}} M$ is a sub-module of M then P is an affine subspace of M. And the dimension of P as a module is precisely the dimension of P as an affine subspace [by taking $s = 0$].

(ii) Conversely any affine subspace $S \subseteq M$ is of the form $S = p + P$ for some $p \in M$ and some sub-module $P \subseteq M$. We will mostly regard the case of a **line** - a 1-dimensional affine space in M

$$S = p + Ru$$

for some $0 \neq u \in R$ or a **plane** in M. The latter is spanned by two (linearly independent) elements $u, v \in M$ and hence is a 2-dimensional affine space in M

$$S = p + Ru + Rv$$

(iii) If $\{ S_i \mid i \in I \}$ is an arbitrary collection of affine spaces $S_i \subseteq M$, then their intersections either empty of another affine space in M

$$\bigcap_{i\in I} S_i \subseteq M \text{ affine space} \iff \bigcap_{i\in I} S_i \neq \emptyset$$

Prob If $S := \bigcap_i S_i$ is empty, then there is nothing to prove. If not we pick up some $p \in S$. As $p \in S \subseteq S_i$ for any $i \in I$ we find that $P_i := S_i - p \leq_{\mathfrak{m}} M$ is a sub-module of M. Let $P := \bigcap_i P_i \leq_{\mathfrak{m}} M$, then we will show: $S = p + P$. As $P \subseteq P_i$ for any $i \in I$ we clearly have $p + P \subseteq p + P_i = S_i$. Conversely if $x \in S$ then $x - p \in S_i - p = P_i$ for any $i \in I$. Thus $x - p \in P$ such that $x \in p + P$. And by $S = p + P$ it is clear that S is an affine space.

Elementary geometry usually starts in the some space $\mathbb{R}^n$ and considers points, lines, line segments, triangles, quadrangles and such. Using set theory we may model all these objects as subsets of the ambient space. E.g. the triangle $T = ABC$ in $\mathbb{R}^n$ is the collection of points in $\mathbb{R}^n$ that lie inside T. We will now formalize these notions: Thereby the triangle $ABC \subseteq \mathbb{R}^n$ will be the convex hull $\mathrm{Ch}\{ A, B, C \}$ of the points A, B, $C \in \mathbb{R}^n$. Generally speaking $A_1A_2 \ldots A_m$ is just another notation for $\mathrm{Ch}\{ A_1, A_2, \ldots, A_m \}$.

(4.118) Definition:
Let V be an $\mathbb{R}$-vector-space, x, $y \in V$ be two points in V and C, $X \subseteq V$ be subsets of V. Then we define the following notions

(i) We denote the **line segment** from x to y (that is the set of points in V starting in x and going straight to y) by $[x, y]$. Formally that is

$$\begin{aligned} [x,y] &:= \{ ax + by \mid a, b \in \mathbb{R}^+,\ a + b = 1 \} \\ &= \{ x + b(y - x) \mid b \in \mathbb{R},\ 0 \leq a \leq 1 \} \end{aligned}$$

(ii) We say that $C \subseteq V$ is a **convex** set, iff for any two points x, $y \in C$ the line from x to y is contained in C. Formally again this is the property

$$\forall\, x,\, y \in C \ :\ [x,y] \subseteq C$$

(iii) For a finite set $X = \{ x_1, \ldots, x_n \} \subseteq V$ we define the **convex hull** of X to be the set of all convex combinations of the elements $x_k \in X$

$$\mathrm{Ch}\{ x_1, \ldots, x_n \} := \left\{ \sum_{k=1}^{n} a_k x_k \;\middle|\; a_k \in \mathbb{R}^+,\ \sum_{k=1}^{n} a_k = 1 \right\}$$

Likewise the **convex hull** of an arbitrary subset $X \subseteq V$ is the set of all convex combinations of any finitely many elements of X

$$\mathrm{Ch}(X) := \left\{ \sum_{k=1}^{n} a_k x_k \;\middle|\; \begin{array}{l} 1 \leq n \in \mathbb{N},\ x_k \in X \\ a_k \in \mathbb{R}^+,\ \sum_{k=1}^{n} a_k = 1 \end{array} \right\}$$

(4.119) Remark:
Examples of convex sets are abundant in elementary geometry: Clearly the empty set $\emptyset \subseteq V$ and any affine space $S \subseteq V$ are convex sets in V. Also any line segment $[x,y] \subseteq V$ is convex. Likewise any triangle, quadrangle and so on are convex sets. In $V = \mathbb{R}^n$ the ball $B_r(m) := \{\, x \in \mathbb{R}^n \mid \|x-m\| \leq r \,\}$ of radius r with center $m \in \mathbb{R}^n$ is convex. This is untrue for the sphere $S_r(m) := \{\, x \in \mathbb{R}^n \mid \|x-m\| = r \,\}$ of radius r with center $m \in \mathbb{R}^n$ however.

(4.120) Proposition: (viz. 950)
If V be an $\mathbb{R}$-vector-space and $X \subseteq V$ is an arbitrary subset of V the following 3 statements are true

(i) The convex hull $\mathrm{Ch}(X) \subseteq V$ of X is a convex set. And if $x \in X$ is any fixed element of X, then we can also write it, as

$$\mathrm{Ch}(X) \;=\; x + \left\{ \sum_{k=1}^{n} a_k(x_k - x) \;\middle|\; \begin{array}{l} 1 \leq n \in \mathbb{N},\ x_k \in X \\ a_k \in \mathbb{R}^+,\ \sum_{k=1}^{n} a_k \leq 1 \end{array} \right\}$$

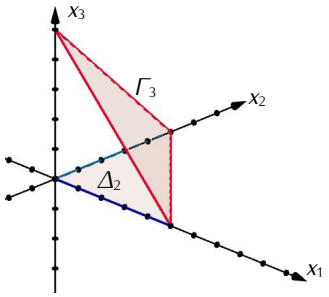
(ii) If $I \neq \emptyset$ is any index set and for any $i \in I$ we are given some convex set $C_i \subseteq V$, then the intersection of all the C_i is a convex set in V

$$\bigcap_{i \in I} C_i \;\subseteq\; V \text{ is convex}$$

(iii) In particular there is a smallest convex set containing X. It turns out that this is precisely the convex hull of X, that is we have the identity

$$\bigcap \left\{ C \;\middle|\; \begin{array}{l} X \subseteq C \subseteq V, \\ C \text{ is convex} \end{array} \right\} \;=\; \mathrm{Ch}(X)$$

(4.121) Example:
In $\mathbb{R}^n$ the n-dimensional *simplex* is defined to be the convex hull of 0 and the Euclidean basis vectors e_1 to e_n. Intuitively speaking, this is the pyramid attached at 1 at every coordinate axis with apex in 0



$$\Delta_n \;:=\; \mathrm{Ch}\{\, 0, e_1, \ldots, e_n \,\}$$

As 0 is an element of the generating set of Δ_n we may use (4.120.(i)) (or an immediate comparison) to rewrite this into the following form

$$\Delta_n \;=\; \left\{ (t_1, \ldots, t_n) \in \mathbb{R}^n \;\middle|\; t_k \in \mathbb{R}^+,\ \sum_{k=1}^{n} t_k \leq 1 \right\}$$

We see that Δ_n contains a *facet* Γ_n that is projected $P(\Gamma_n) = \Delta_{n-1}$ onto the $(n-1)$-dimensional simplex $\Delta_{n-1} \subseteq \mathbb{R}^{n-1} \subseteq \mathbb{R}^n$ under the *forgetful map* $P : \mathbb{R}^n \twoheadrightarrow \mathbb{R}^{n-1} : (t_1, t_2, \ldots, t_n) \mapsto (t_2, \ldots, t_n)$

$$\Gamma_n \;=\; \left\{ (t_1, \ldots, t_n) \in \mathbb{R}^n \;\middle|\; t_k \in \mathbb{R}^+,\ \sum_{k=1}^{n} t_k = 1 \right\}$$

(4.122) Proposition: (viz. 951)
Let $1 \leq n \in \mathbb{N}$ and $x \in \mathbb{F}^n$ be a point of n-dimensional space, where $\mathbb{F} \in \{ \mathbb{R}, \mathbb{C} \}$. Then the following statements are true:

(i) If $U \leq_v \mathbb{F}^n$ is a subspace of $\mathbb{F}^n$ then there is a uniquely determined orthogonal projection $p \in U$ of x. And if we choose $\{ g_1, \ldots, g_r, \ldots, g_n \} \subseteq \mathbb{F}^n$ an ONB of $\mathbb{F}^n$ such that $U = \mathrm{Lh}\{ g_1, \ldots, g_r \}$ then we can even compute p by

$$p \;=\; \sum_{k=1}^{r} \langle x \mid g_k \rangle \, g_k$$

(ii) If $S \subseteq \mathbb{F}^n$ is an affine subspace of $\mathbb{F}^n$ then there is a uniquely determined orthogonal projection $p \in S$ of x. And if $s \in S$ is any point in S then we can compute p in the following way: Choose an ONB $\{ g_1, \ldots, g_r, \ldots, g_n \} \subseteq \mathbb{F}^n$ of $\mathbb{F}^n$ such that $S - s = \mathrm{Lh}\{ g_1, \ldots, g_r \}$ then p is given to be

$$p \;=\; s + \sum_{k=1}^{r} \langle x - s \mid g_k \rangle \, g_k$$

(iii) If S is a line in $\mathbb{F}^n$, that is $S = \{ s + au \mid a \in \mathbb{F} \}$ for some points s and $u \in \mathbb{F}^n$ with $u \neq 0$, then the orthogonal projection p of x to S is uniquely determined and can be computed, by

$$p \;=\; s + au \quad \text{where} \quad a \;=\; \frac{\langle x - s, u \rangle}{\|u\|^2}$$

(4.123) Lemma: (viz. 953)
Let $2 \leq n \in \mathbb{N}$ and let $x, y \in \mathbb{R}^n$ be two n-tuples. Then we consider the triangle ABC defined by the points $A = 0 \in R^n$, $B = x$ and $C = y$. Now the angle α in A of ABC satisfies the equation

$$\langle x, y \rangle \;=\; \|x\| \cdot \|y\| \cdot \cos(\alpha)$$

(4.124) Remark:
Lemma (4.123) yields the interpretation of the scalar product as a way to measure the angle α between two vectors x and $y \in \mathbb{R}^n$

$$\cos(\alpha) \;=\; \frac{\langle x, y \rangle}{\|x\| \cdot \|y\|}$$

Note that x and y are perpendicular iff $\cos(\alpha) = 0$ and this is the case iff the scalar product vanishes

$$x \perp y \quad \Longleftrightarrow \quad \langle x, y \rangle \;=\; 0$$

This is formally true for any $x, y \in \mathbb{R}^n$ but we will use this interpretation far more generally by *defining* x and $y \in H$ in a Hilbert space to be perpendicular iff the inner product $\langle x \mid y \rangle = 0$ vanishes. In this sense we can speak of orthogonal functions $f, g : X \to \mathbb{C}$ for example. In the case of the base field $\mathbb{C}$ the interpretation of the angle is a little obscure. But the same reasoning yields the following result: Consider the complex *lines* $\mathbb{C}w$ and $\mathbb{C}z$ where $w, z \in \mathbb{C}^n$. There are two angles α and α' between these lines that sum up to $\alpha + \alpha' = \pi$. Let $\alpha \leq \alpha'$ be the smaller of the two, then

$$|\langle w \mid z \rangle| \;=\; \|w\| \cdot \|z\| \cdot \cos(\alpha)$$

In 2 dimensions - in the plane $\mathbb{R}^2$ - it is clear that for any given direction, defined by $0 \neq x = (x_1, x_2) \in \mathbb{R}^2$ there is precisely one direction $n = (n_1, n_2)$ perpendicular to it. As we have just seen this n has to satisfy the equation

$$x_1 n_1 + x_2 n_2 \;=\; \langle x, n \rangle \;=\; 0$$

This is a homogeneous, linear equation, so the set of solutions $\{ x \}^\perp$ is a subspace of $\mathbb{R}^2$ - not surprisingly, as only the direction of n is determined, not its length. And we immediately see the set of solutions

$$n \;\in\; \{ x \}^\perp \;=\; \mathbb{R} \begin{pmatrix} x_2 \\ -x_1 \end{pmatrix}$$

So what happens in 3 dimensions? Suppose we fix 2 directions by giving a vectors $x, y \in \mathbb{R}^3$. Unless x and y are colinear (= linear dependent) there should be precisely one direction n perpendicular to both x and y. This time n has to satisfy 2 equations, namely

$$\begin{aligned} x_1 n_1 + x_2 n_2 + x_3 n_3 \;&=\; \langle x, n \rangle \;=\; 0 \\ y_1 n_1 + y_2 n_2 + y_3 n_3 \;&=\; \langle y, n \rangle \;=\; 0 \end{aligned}$$

Let us try to solve this system of linear equations, by eliminating a variable: If we multiply the first equation by y_1 and the second equation by x_1 we can eliminate n_1 by subtracting. Then we use the "2d"-trick to guess a solution (n_2, n_3) of this equation with two variables, only

$$\underbrace{(x_2 y_1 - x_1 y_2)}_{-n_3} n_2 + \underbrace{(x_3 y_1 - x_1 y_3)}_{n_2} n_3 \;=\; 0$$

In order to find n_1 we eliminate n_3 by multiplying the first equation with y_3, the second with x_3 and subtracting again. This time we find

$$\underbrace{(x_1 y_3 - x_3 y_1)}_{-n_2} n_1 + \underbrace{(x_2 y_3 - x_3 y_2)}_{n_1} n_2 \;=\; 0$$

We see that our solution for n_2 agrees, so it seems we have stumbled upon something interesting: The direction $\{ x, y \}^\perp$ perpendicular to both x and $y \in \mathbb{R}^3$ seems to be given by

$$n \;\in\; \{ x, y \}^\perp \;=\; \mathbb{R} \begin{pmatrix} x_2 y_3 - x_3 y_2 \\ x_3 y_1 - x_1 y_3 \\ x_1 y_2 - x_2 y_1 \end{pmatrix}$$

(4.125) Definition:
Let $(R,+,\cdot)$ be a commutative ring and consider two triples $x=(x_1,x_2,x_3)$ and $y=(y_1,y_2,y_3)\in R^3$ then we define the **wedge product** (which is more commonly called **cross product**) of x and y by

$$\begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} \wedge \begin{pmatrix} y_1 \\ y_2 \\ y_3 \end{pmatrix} := \begin{pmatrix} x_2y_3 - x_3y_2 \\ x_3y_1 - x_1y_3 \\ x_1y_2 - x_2y_1 \end{pmatrix}$$

The wedge product is a classic construction that has surprisingly many applications. What we are interested in here, is that we may define a plane in $\mathbb{R}^3$ by giving a vector perpendicular to it. But the wedge product may also be used to compute the area of a parallelogram or the volume of a parallelepiped in $\mathbb{R}^3$. So how do we define these objects in vector geometry?

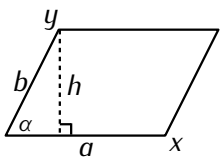
(4.126) Proposition: (viz. 954)
If $(R,+,\cdot)$ is any commutative ring, a, b and $x\in R^3$ such that $a\wedge x=b$, then we find that $\langle a,b\rangle=0$ and

$$\begin{aligned} a_1x &= \begin{pmatrix} 0 \\ b_3 \\ -b_2 \end{pmatrix} + x_1a \\ a_2x &= \begin{pmatrix} -b_3 \\ 0 \\ b_1 \end{pmatrix} + x_2a \\ a_3x &= \begin{pmatrix} b_2 \\ -b_1 \\ 0 \end{pmatrix} + x_3a \end{aligned}$$

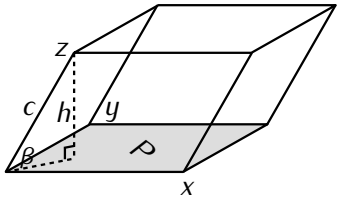
Conversely: In case $\langle a,b\rangle=0$ and $a_1\in R^*$ we thereby find that the set of solutions x of the equation $a\wedge x=b$ is the following line in R^3

$$\{\, x\in R^3 \mid a\wedge x=b \,\} = \begin{pmatrix} 0 \\ a_1^{-1}b_3 \\ -a_1^{-1}b_2 \end{pmatrix} + Ra$$

Likewise, if $\langle a,b\rangle=0$ and $a_2\in R^*$ respectively if $a_3\in R^*$ then we find the following analoguos identities



$$\{\, x\in R^3 \mid a\wedge x=b \,\} = \begin{pmatrix} -a_2^{-1}b_3 \\ 0 \\ a_2^{-1}b_1 \end{pmatrix} + Ra$$



$$\{\, x\in R^3 \mid a\wedge x=b \,\} = \begin{pmatrix} a_3^{-1}b_2 \\ -a_3^{-1}b_1 \\ 0 \end{pmatrix} + Ra$$

(4.127) Definition:
Let V be an $\mathbb{R}$-vector space and $x_1, \ldots, x_k \in V$ be any vectors in V. Then we define the **parallelotope** spanned by the x_i to be the linear hull of the x_i with coefficients $0 \leq a_i \leq 1$ only

$$\mathrm{Ph}\{\, x_1, \ldots, x_n \,\} \;:=\; \left\{ \sum_{i=1}^{k} a_i x_i \mid a_i \in [0,1] \right\}$$

Let us append some elementary geometry: In planar geometry a parallelotope $P = \mathrm{Ph}\{\, x, y \,\}$ (where x, $y \in \mathbb{R}^3$) is called a *parallelogram*. In this case we define the *area* of P as shown in the figure below. And in spatial geometry a parallelotope $Q = \mathrm{Ph}\{\, x, y, z \,\}$ (where x, y, $z \in \mathbb{R}^3$) is called a *parallelepiped*. In this case we define its *volume* as shown in the figure:

$\mathrm{Area}(P) = ah = ab{\cdot}\sin(\alpha)$

$\mathrm{Vol}(Q) = \mathrm{Area}(P){\cdot}h$
$= \mathrm{Area}(P){\cdot}c{\cdot}\sin(\beta)$

(4.128) Proposition: (viz. 955)
If $(R, +, \cdot)$ is a commutative ring and we are given five triples u, v, x, y and $z \in R^3$ then the wedge product satisfies the following properties

(1) $x \wedge x \;=\; 0$

(2) $x \wedge y \;=\; -(y \wedge x)$

(3) $R^3 \times R^3 \to R^3 : (x, y) \mapsto x \wedge y$ is bilinear

(4) $(x \wedge y) \perp x$ and $(x \wedge y) \perp y$

(5) $x \wedge y \;=\; \begin{pmatrix} 0 & -x_3 & x_2 \\ x_3 & 0 & -x_1 \\ -x_2 & x_1 & 0 \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \\ y_3 \end{pmatrix}$

(6) $\langle x \wedge y, z \rangle \;=\; \det \begin{pmatrix} | & | & | \\ x & y & z \\ | & | & | \end{pmatrix}$

(7) $x \wedge (y \wedge z) \;=\; \langle x, z \rangle\, y - \langle x, y \rangle\, z$

(8) $x \wedge (y \wedge z) + y \wedge (z \wedge x) + z \wedge (x \wedge y) \;=\; 0$

(9) $\langle u \wedge v, x \wedge y \rangle \;=\; \langle u, x \rangle \cdot \langle v, y \rangle - \langle u, y \rangle \cdot \langle v, x \rangle$

(10) $x \wedge y \neq 0 \iff \{\, x, y \,\}$ linear independent

Hereby property (7) is called the *Jacobi* and (9) is called the *Lagrange identity* of the wedge product. And if $A \in \mathrm{mat}_3(R)$ is any matrix, then we have the *transformation formula* (where $\mathrm{cof}(A)$ is the cofactor matrix of A, i.e. the matrix of (2×2)-minors of A)

$$(Ax) \wedge (Ay) \;=\; \mathrm{cof}(A)(x \wedge y)$$

Now, if $R = \mathbb{R}$ then the norm of the cross product is precisely the area of the parallelogram spanned by x and y. That is if α is the angle between theg vectors x and y then we get

$$\|x \wedge y\| = \mathrm{Area}\big(\mathrm{Ph}\{\, x, y \,\}\big) = \|x\| \cdot \|y\| \cdot \sin(\alpha)$$

Likewise, if x, y and $z \in \mathbb{R}^3$ then the volume of the *parallelepiped* spanned by x, y and z can be computed using the *triple product* of x, y and z

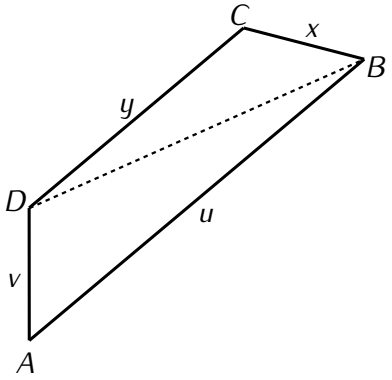
$$\langle x \wedge y, z \rangle \;=\; \mathrm{Vol}\big(\mathrm{Ph}\{\, x, y, z \,\}\big)$$

(4.129) Remark: $(\diamondsuit)$
In the definition of the area of a parallelogram or the volume of a parallelepiped we strongly appealed to the intuition of the reader. There is an entire mathematical discipline called *measure theory* dedicated to the problem of defining the volume of geometric objects in $\mathbb{R}^n$. The best answer to this problem is the *Lebesgue-measure* and it turns out, not all subsets $X \subseteq \mathbb{R}^n$ can be assigned a reasonable volume. There are X that are just too weird, to do so (e.g. the *Banach-Tarski-Paradox*).
A very readable introduction to the topic is the first chapter of [Bauer, Maß- und Integrationstheorie]. Theorem (8.4) in this textbook states that for any $\mathbb{R}$-linear $\varphi : \mathbb{R}^n \to \mathbb{R}^n$ and any Borel set $A \subseteq \mathbb{R}^n$ [that is a set that can be assigned a reasonable volume] the Lebesgue-measure λ satisfies

$$\lambda\big(\varphi(A)\big) \;=\; \det(\varphi) \cdot \lambda(A)$$

In this light the volume formula above is just a special case of this: Define $\varphi : \mathbb{R}^3 \to \mathbb{R}^3$ by $\varphi(e_1) := x$, $\varphi(e_2) := y$ and $\varphi(e_3) := z$. Take $C := [0,1]^3$ the standard cube in $\mathbb{R}^3$. It stands to reason, that λ has been defined in such a way as $\lambda(C) = 1$. Then $Q := \varphi(C) = \mathrm{Ph}\{\, x, y, z \,\}$ and we get

$$\mathrm{Vol}(Q) \;=\; \lambda(Q) \;=\; \det(\varphi) \cdot \lambda(C) \;=\; \det \begin{pmatrix} | & | & | \\ x & y & z \\ | & | & | \end{pmatrix} \;=\; \langle x \wedge y, z \rangle$$



(4.130) Example: (viz. 959)
Consider any four points A, B, C and $D \in \mathbb{R}^3$ in three-dimensional space. We say that their convex hull $T := ABCD = \mathrm{Ch}\{\, A, B, C, D \,\}$ is a *trapezoid*, iff these points form a quadrangle in $\mathbb{R}^3$ such that two sides of the quadrangle are parallel. E.g. we may assume the property

$$C - D \;=\; t(B - A)$$

for some $t \in \mathbb{R}^+$. In this case these four points lie in a plane in $\mathbb{R}^3$ as $C = A + t(B - A) + (D - A)$. And the area of T can be computed using the wedge product in the following way

$$\text{Area}(T) \;=\; \frac{1}{2} \left\| \Big((B - A) + (C - D) \Big) \wedge (C - A) \right\|$$

This is due to the fact, that we can decompose the trapezoid $T = ABCD$ into two triangles ABD and BCD and compute their areas using the wedge product of the edges $u = B - A$ and $v = D - A$ for ABD, resp. $x = C - B$ and $y = D - C$ for BCD

(4.131) Theorem: (viz. 959)
Let u and $v \in \mathbb{R}^3$ be any two linearly independent vectors in $\mathbb{R}^3$. Also let $s \in \mathbb{R}^3$ be any point, then we regard the following plane in $\mathbb{R}^3$

$$S \;:=\; s + \text{Lh}\{\, u, v \,\} \;\subseteq\; \mathbb{R}^3$$

If we let $n := u \wedge v$ and $h := \langle n, s \rangle$, then S is the set of solutions x of the linear equation $\langle n, x \rangle = h$, formally that is: S is given to be

$$S \;=\; \big\{\, x \in \mathbb{R}^3 \mid \langle u \wedge v, x \rangle = \langle u \wedge v, s \rangle \,\big\}$$

(4.132) Remark:
The above theorem tells us that there are two ways to define a plane S in $\mathbb{R}^3$: First of all we can give a *parametrization* of S, that is we choose a starting point $s \in \mathbb{R}^3$ and two directions u, $v \in \mathbb{R}^3$ (note that $\{\, u, v \,\}$ has to be linearly independent, to span a plane) and take S to be the set

$$S \;:=\; s + \mathbb{R}u + \mathbb{R}v \;\subseteq\; \mathbb{R}^3$$

Secondly we can describe S *implicitly* by giving an equation $f(x) = 0$ such that S is comprised of all the points $x \in \mathbb{R}^3$ that satisfy the defining equation f. In this case we pick up a perpendicular direction $n = (n_1, n_2, n_3) \in \mathbb{R}^3$ (which should be non-zero $n \neq 0$ to define a plane) and some scalar $h \in \mathbb{R}$ and take $f(x) = \langle n, x \rangle - h$. That is

$$H \;:=\; \big\{\, x \in \mathbb{R}^3 \mid n_1 x_1 + n_2 x_2 + n_3 x_3 = h \,\big\}$$

By the theorem above, we can take $n := u \wedge v$ and $h := \langle n, s \rangle$ then these planes agree $H = S$. Conversely, if we are given H in implicit form it also is easy to find a parametrization S: As $n \neq 0$ there is some $n_i \neq 0$, say $n_3 \neq 0$. We need u, v and $s \in \mathbb{R}^3$ such that $\langle n, u \rangle = 0$, $\langle n, v \rangle = 0$ and $\langle n, s \rangle = 0$. But these are easy to find: For $n_3 \neq 0$ let

$$\begin{aligned} u &:= (n_3, 0, -n_1) \\ v &:= (0, n_3, -n_2) \\ s &:= (0, 0, h/n_3) \end{aligned}$$

Then it is easy to see that $u \wedge v = n_3 n$ and $\langle u \wedge v, s \rangle = n_3 \langle n, s \rangle = n_3 h$. Thus for any $x \in \mathbb{R}^3$ we have $\langle u \wedge v, x \rangle = n_3 \langle n, x \rangle$ and $\langle u \wedge v, s \rangle = n_3 h$, such that $\langle u \wedge v, x \rangle = \langle u \wedge v, s \rangle$ becomes equivalent to $\langle n, x \rangle = h$. By the theorem above this results in $H = S$ such that we can switch freely between a parametrization and an implicit description of a plane in $\mathbb{R}^3$, as needed.

This can even be generalized to arbitrary dimensions $d \geq 2$. Given any $n = (n_1, n_2, \ldots, n_d) \in \mathbb{R}^d$ such that $n \neq 0$ and $h \in \mathbb{R}$ the set of solutions of the equation $\langle n, x \rangle = h$ is said to be a *hyperplane* in $\mathbb{R}^d$

$$H := \left\{ x \in \mathbb{R}^d \mid \langle n, x \rangle = h \right\}$$

This means that the dimension of H is one less, than the dimension of the ambient space $\mathbb{R}^d$. That is we need $d - 1$ vectors $u_1, \ldots, u_{d-1} \in \mathbb{R}^d$ and a starting point $s \in \mathbb{R}^d$ to span H. So let's take a look at

$$S := s + \mathbb{R}u_1 + \cdots + \mathbb{R}u_{d-1} \subseteq \mathbb{R}^d$$

Note that thereby $\{ u_1, \ldots, u_{d-1} \}$ has to be linearly independent of course. So what's the relation between these two descriptions? If $n_d \neq 0$ then it is easy to give the u_i and s again:

$$\begin{aligned} u_i &:= n_d \, e_i - n_i \, e_d \\ s &:= (h/n_d) \, e_d \end{aligned}$$

(where $i \in 1 \ldots d-1$ and $\{ e_1, \ldots, e_d \}$ is the Euclidean basis of $\mathbb{R}^d$). Then $\langle n, u_i \rangle = 0$ and $\langle n, s \rangle = h$ such that $S \subseteq H$. But as both have the same dimension this means $S = H$. The converse direction requires some more effort however: Regard the matrix $U \in \mathrm{mat}_{(d-1),d}(\mathbb{R})$ that has the rows $\mathrm{row}_i(U) = u_i$. That is $Ux = (\langle u_1, x \rangle, \ldots, \langle u_{d-1}, x \rangle)$. As the u_i are linearly independent it has row-rank $d - 1$ and hence $x \mapsto Ux$ is surjective. By the dimension formula this means that its kernel is 1-dimensional, that is $\mathrm{kn}(U) = \mathbb{R}n$ for some $n \neq 0$. We can find this n using the Gaussian elimination algorithm. Thus if we let $h := \langle n, s \rangle$ again then we have found n and h such that $H = S$. The computation of n is precisely what the wedge product does in three dimensions.

Let us append a final comment on this, without going into details: The equivalence of an explicit parametrization S and an implicit description H remains true in the much more general setting of differential geometry:

An r-dimensional *submanifold* of $\mathbb{R}^d$ is a subset $M \subseteq \mathbb{R}^d$ that can locally be parametrisized by (differentiable) maps $\varphi : D \subseteq \mathbb{R}^r \hookrightarrow M \subseteq \mathbb{R}^d$. And it turns out that this is equivalent to saying, that locally M can be described as the set of roots $M \cap U = \{ x \in U \mid f(x) = 0 \}$ of some (differentiable) function $f : U \subseteq \mathbb{R}^d \to \mathbb{R}$. But this is an entirely different story.

(4.133) Remark:
An elementary problem in geometry is the following: We are given a point $x = (x_1, x_2) \in \mathbb{R}^2$ and want to rotate it by the angle $\varphi \in [0, 2\pi]$ around the center of rotation $c = (c_1, c_2) \in \mathbb{R}^2$. Which coordinates $x' \in \mathbb{R}^2$ is x mapped to? The answer is rather simple

$$x' \;=\; \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} + \begin{pmatrix} \cos(\varphi & -\sin(\varphi) \\ \sin(\varphi) & \cos(\varphi) \end{pmatrix} \begin{pmatrix} c_1 - x_1 \\ c_2 - x_2 \end{pmatrix}$$

This can also be expressed in terms of complex numbers: The multiplication by $e^{i\varphi} = \cos(\varphi) + i\sin(\varphi)$ rotates $z \in \mathbb{C}$ by the angle φ around $0 \in \mathbb{C}$. Thus if $c = c_1 + ic_2$ and $x = x_1 + ix_2$ then

$$x' \;=\; c + e^{i\varphi} \cdot (x - c)$$

(4.134) Remark:
Rotations in spatial geometry require some more information: First of all we need to fix a center $c \in \mathbb{R}^3$ of rotation and a rotation axis, which is defined by some vector $n \in \mathbb{R}^3$ with $n \neq 0$. Now we want to rotate a point $x \in \mathbb{R}^3$ by the angle $\varphi \in [0, 2\pi]$. To do this we need an orthonormal basis $\{ u_1, u_2, u_3 \}$ of $\mathbb{R}^3$ in which the rotation axis is a coordinate axis. If $n_1 \neq 0$ this can be achieved by

$$u_1 \;=\; \frac{1}{a} \begin{pmatrix} -n_2 \\ n_1 \\ 0 \end{pmatrix}, \;\; u_2 \;=\; \frac{1}{ab} \begin{pmatrix} -n_1 n_3 \\ -n_2 n_3 \\ n_1^2 + n_2^2 \end{pmatrix}, \;\; u_3 \;=\; \frac{1}{b} \begin{pmatrix} n_1 \\ n_2 \\ n_3 \end{pmatrix}$$

where $a := \sqrt{n_1^2 + n_2^2}$ and $b := \sqrt{n_1^2 + n_2^2 + n_3^2}$. Then u_1 and u_2 are a basis of the plane E defined by $\langle x, n \rangle = 0$ and u_3 is perpendicular to E. In case $n_1 = 0$ the same is true for

$$u_1 \;=\; \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \;\; u_2 \;=\; \frac{1}{b} \begin{pmatrix} 0 \\ n_3 \\ -n_2 \end{pmatrix}, \;\; u_3 \;=\; \frac{1}{b} \begin{pmatrix} 0 \\ n_2 \\ n_3 \end{pmatrix}$$

In any case, all we need to do is rotate to find a basis representation of $x - c$ in the basis $\{ u_1, u_2, u_3 \}$ and rotate the first two coefficients as we did in $\mathbb{R}^2$. As $\{ u_1, u_2, u_3 \}$ is an ONB the basis representation is easy to find by evaluating scalar products: If $r_k := \langle x - c, u_k \rangle$ then $x - c = r_1 u_1 + r_2 u_2 + r_3 u_3$ and thereby x is rotated onto

$$x' \;=\; c + \Big(r_1 \cos(\varphi) - r_2 \sin(\varphi) \Big) u_1 + \Big(r_1 \sin(\varphi) + r_2 \cos(\varphi) \Big) u_2 + r_3 u_3$$

Analogous to the planar case, there is a way of expressing this using quaternions: First of all we employ the usual embedding $\mathbb{R}^3 \hookrightarrow \mathbb{H}$ that takes $x = (x_1, x_2, x_3) \mapsto ix_1 + jx_2 + kx_3$ that is $x \in \mathbb{R}^3$ is mapped to a quaternion with real part 0. Then we encode n and φ in $q \in \mathbb{H}$ by

$$q \;:=\; \cos\left(\frac{\varphi}{2}\right) + \sin\left(\frac{\varphi}{2}\right) \|n\|^{-1} \left(in_1 + jn_2 + kn_3\right)$$

Then $x \in \mathbb{R}^3$ is mapped onto the point $x' \in \mathbb{R}^3$ under rotation, where x' can be computed using the following conjugation with q

$$x' \;=\; c + \mathrm{im}\Big(q(x-c)q^{-1}\Big)$$

(4.135) Remark: $(\diamondsuit)$
As we have just argued the plane perpendicular to $n = (n_1, n_2, n_3) \in \mathbb{R}^3$ (where $n \neq 0$) that contains the point $s = (s_1, s_2, s_3) \in \mathbb{R}^3$ is defined by the equation

$$n_1x_1 + n_2x_2 + n_3x_3 \;=\; n_1s_1 + n_2s_2 + n_3s_3$$

Thereby "defined by" clearly means, that it consists of all the solutions $x = (x_1, x_2, x_3) \in \mathbb{R}^3$ that satisfy this equation. Likewise we have seen that the equation

$$\big(x_1 - c_1\big)^2 + \big(x_2 - c_2\big)^2 + \big(x_3 - c_3\big)^2 \;=\; r^2$$

defines a sphere of radius $r > 0$ around the center $c = (c_1, c_2, c_3) \in \mathbb{R}^3$ (in the same sense). Intersecting to planes we get a line. Algebraically speaking that is: We only allow those $x \in \mathbb{R}^3$ that satisfy both equations of the respective planes. Likewise the intersection of a sphere and a plane is a circle in space. Thus the intersection of geometric objects yields another geometric object (that may be empty).
Note that the equations we used here are polynomial, this is the restriction we use in algebraic geometry. So generally speaking a geometric object $X \subseteq \mathbb{R}^n$ in this sense is the common zero-locus of a set of polynomials $F \subseteq \mathbb{R}[t_1, \ldots, t_n]$ (it is called an *affine variety* over $\mathbb{R}$ or any other field). That is

$$X \;=\; \mathbb{V}(F) \;:=\; \{\, x \in \mathbb{R}^n \mid \forall\, f \in F \,:\, f(x) = 0 \,\}$$

The mathematical field of algebraic geometry now tries to glean geometric properties of X by studying the algebraic properties of the ring $\mathcal{O}(X)$ of polynomial functions on X. That is $p \in \mathcal{O}(X)$ is a so-called *regular* function $p : X \to \mathbb{R}$ on X, if indeed there is a polynomial $f \in \mathbb{R}[t_1, \ldots, t_n]$ such that $p(x) = f(x)$ for any $x \in X$. So let $q \in \mathcal{O}(X)$ be another regular function on X, induced by the polynomial $g \in \mathbb{R}[t_1, \ldots, t_n]$. When are p and q identical? Clearly iff

$$\begin{aligned} p = q \;&\iff\; \forall\, x \in X \,:\, f(x) \,=\, g(x) \\ &\iff\; f - g \,\in\, \{\, h \in \mathbb{R}[t_1, \ldots, t_n] \mid \forall\, x \in X : h(x) = 0 \,\} \end{aligned}$$

It is plain to see that the set $\mathbb{I}(X) := \{\, h \in \mathbb{R}[t_1, \ldots, t_n] \mid \forall\, x \in X : h(x) = 0 \,\}$ is an ideal in the polynomial ring $\mathbb{R}[t_1, \ldots, t_n]$. It is called the *vanishing ideal* of X. So the boon here is, that the ring of regular functions is nothing but a residue of the polynomial ring

$$\mathbb{R}[t_1, \ldots, t_n] \Big/ \mathbb{I}(X) \;\cong_{\mathrm{r}}\; \mathcal{O}(X) \;:\; f + \mathbb{I}(X) \;\mapsto\; \big(x \mapsto f(x)\big)$$

4.9 Linear Optimization

Chapter 5

Structure Theorems

5.1 Primary Decomposition

In section 2.8 we introduced the notion of *primary ideals* and the *primary decomposition* of an ideal $\mathfrak{a} \trianglelefteq_\mathfrak{i} R$. The theory culminated in the theorem of Lasker-Noether: If R is a noetherian ring and $\mathfrak{a} \neq R$ is a proper ideal, then $\mathfrak{a}$ admits a minimal primary decomposition. That is there are some primary ideals $\mathfrak{a}_1, \ldots, \mathfrak{a}_k \in \operatorname{Spri}(R)$ such that $\mathfrak{a}$ is the intersection of the $\mathfrak{a}_i$ but not of a subset of these. That is for any $j \in 1 \ldots k$ we get

$$\begin{aligned} \mathfrak{a} &= \bigcap_{i=1}^{k} \mathfrak{a}_i \\ \mathfrak{a} &\neq \bigcap_{i \neq j} \mathfrak{a}_i \end{aligned}$$

Also, if we denote $\mathfrak{p}_i := \sqrt{\mathfrak{a}_i}$ and $\operatorname{ass}(\mathfrak{a}) := \{\, \mathfrak{p}_1, \ldots, \mathfrak{p}_k \,\}$, then $\mathfrak{p}_i \in \operatorname{Spec}(R)$, as the $\mathfrak{a}_i$ are primary ideals. And we can choose the $\mathfrak{a}_i$ in such a way, that the $\mathfrak{p}_i$ are pairwise distinct [all we have to do, is to take the intersection of all the $\mathfrak{a}_i$ that belong to the same associated ideal $\mathfrak{p} \in \operatorname{ass}(\mathfrak{a})$, then the resulting intersections are a new set of $\mathfrak{a}_i$ that satisfy the properties above and]

$$\forall\, i, j \in 1 \ldots k \;:\; \mathfrak{p}_i = \mathfrak{p}_j \implies i = j$$

And in this case the following information on $\mathfrak{a}$ is uniquely determined: (1) the number k of ideals in the primary decomposition, (2) the set $\operatorname{ass}(\mathfrak{a})$ of associate prime ideals and (3) the so-called *isolated components* of $\mathfrak{a}$. These are the primary ideals $\mathfrak{a}_i$ for which $\mathfrak{p}_i$ is a minimal element of $\operatorname{ass}(\mathfrak{a})$. Formally that is: The following set is uniquely determined, as well

$$\operatorname{iso}(\mathfrak{a}) := \left\{ \mathfrak{a}_j \;\middle|\; \forall\, i \in 1 \ldots k \;:\; \mathfrak{p}_i \subseteq \mathfrak{p}_j \implies \mathfrak{p}_i = \mathfrak{p}_j \right\}$$

In fact the minimal elements of $\operatorname{ass}(\mathfrak{a})$ are precisely the prime ideals that are minimal over $\mathfrak{a}$. Therefore the set of isolated components of $\mathfrak{a}$ can also be expressed in the following way

$$\operatorname{iso}(\mathfrak{a}) = \left\{ \mathfrak{a}_j \;\middle|\; \mathfrak{p}_j \in \{\, \mathfrak{q} \in \operatorname{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{q} \,\}_* \right\}$$

Note that ideals $\mathfrak{a} \trianglelefteq_\mathfrak{i} R$ are nothing but modules over R. So in this section we will generalize the Lasker-Noether-decomposition to the case of modules over a commutative ring R. In order to do so we

will have to introduce the notion of a prime ideal *associated* to a module M. This decomposition will be used to prove the uniqueness of the invariant factors, but the notion of an associated prime ideal is of importance in its own right.

(5.1) Definition:
Let $(R,+,\cdot)$ be a commutative ring, M be an R-module, $L \leq_{\mathfrak{m}} M$ a sub-module of M and consider some $p \in R$. Then we define the **p-primary** component $L(p)$ of L to be the subset of elements of L that are annihilated by some power of a, formally that is

$$L(p) \;:=\; \{\, x \in L \mid \exists\, n \in \mathbb{N} : p^n x = 0 \,\}$$

And we say that p **annihilates** L, iff $L = L(p)$, that is iff for any $x \in L$ there is some $n \in \mathbb{N}$ such that $p^n x = 0$. Note that different x may require different powers n of p.

(5.2) Remark:
In mathematical literature there are an awful lot of ambiguities concerning this topic. The primary component $L(p)$ is often denoted L_p but this can be confused with the localizations $\{1, p, p^2, \dots\}^{-1} L$ or even $(R \setminus pR)^{-1}R$. Hence we chose a different notation. Also some textbooks say that L is *primary* if $L = L(p)$ for some prime element $p \in R$. This notion only is suitable over PIDs however. Hence we will reserve the word *primary* for a more general notion, that has to be introduced yet and will work fine over general noetherian rings R. This notion will be taken from Bourbaki.

(5.3) Proposition: (viz. 1154)
Let $(R,+,\cdot)$ be a commutative ring, fix some $p \in R$, let M be an R-module and consider $L \leq_{\mathfrak{m}} M$ a sub-module of M. Then the following statements are true

(i) Clearly for any $a \in R$ we have $L(p) \subseteq L(ap)$.

(ii) The p-primary component $L(p)$ of L is a sub-module of L, formally: $L(p) \leq_{\mathfrak{m}} L \leq_{\mathfrak{m}} M$.

(iii) We find that p annihilates M if and only if p annihilates both L and the residue module M/L. That is the following two statements are equivalent:

 (a) p annihilates M

 (b) p annihilates both, L and M/L

(iv) If p annihilates finitely many sub-modules $L_1, \dots, L_r \leq_{\mathfrak{m}} M$ [that is if for any $i \in 1 \dots r$ we have $L_i(p) = L_i$], then p also annihilates their sum $L_1 + \cdots + L_r \leq_{\mathfrak{m}} M$, too.

(v) If N is another R-module and $\varphi : M \to N$ is a homomorphism of R-modules, then for any $p \in R$ we have the inclusion $\varphi(M(p)) \subseteq N(p)$. And if φ is injective we also have $\varphi^{-1}(N(p)) \subseteq M(p)$.

(5.4) Example: (viz. 1153)
Let $(R,+,\cdot)$ be an UFD, $s \in \mathbb{N}$ and for any $j \in 1\ldots s$ let $p(j) \in R$ be a prime element of R, such that the $p(j)$ are non-associated, that is for any $j, k \in 1\ldots s$ we suppose $p(j) \approx q(k) \implies j = k$. Also for any $j \in 1\ldots s$ let $1 \leq I(j) \in \mathbb{N}$ and for $i \in 1\ldots I(j)$ let $1 \geq n(i,j) \in \mathbb{N}$. Then we regard the R-module

$$M \;:=\; \bigoplus_{j=1}^{s} \bigoplus_{i=1}^{I(j)} R \Big/ p(j)^{n(i,j)} R$$

Note that the torsion part of any finitely generated module over a PID can be written in this *invariant factor form*, as we will see in section 5.2. Then for any prime $q \in R$ we either have $M(q) = 0$ iff $q \approx p(j)$ is untrue for all $j \in 1\ldots s$ and conversely, if $q \approx p(k)$ for some $k \in 1\ldots s$, then

$$M(q) \;=\; \bigoplus_{i=1}^{I(k)} R \Big/ p(k)^{n(i,k)} R$$

(5.5) Definition:
Let $(R,+,\cdot)$ be a commutative ring and M be an R-module. Recall that for any $x \in M$ we defined the **annihilator** of x to be the ideal of all $a \in R$ such that $ax = 0$, that is

$$\operatorname{ann}_R(x) \;:=\; \operatorname{kn}\big(R \to M \;:\; a \mapsto ax\big) \quad \trianglelefteq_{\mathrm{i}} \quad R$$

(i) The set of all proper annihilators of M is denoted by $\operatorname{Anns}_R(M)$. The set of annihilator ideals, that also are prime ideals called the **annihilator spectrum** of M and is denoted, by $\operatorname{Sann}_R(M)$. That is

$$\begin{aligned} \operatorname{Anns}_R(M) &:= \{\, \operatorname{ann}_R(x) \mid 0 \neq x \in M \,\} \quad \subseteq \quad \operatorname{Ideal}(R) \\ \operatorname{Sann}_R(M) &:= \operatorname{Anns}_R(M) \cap \operatorname{Spec}(R) \end{aligned}$$

If the base ring R is understood, we will usually omit the index R in all these notations and just write $\operatorname{ann}(x)$, $\operatorname{Anns}(M)$ and $\operatorname{Sann}(M)$ instead.

(ii) A prime annihilator ideal $\mathfrak{p} \in \operatorname{Sann}(M)$ of M is said to be an **isolated prime** iff it is minimal in $\operatorname{Sann}(M)$, that is iff for any $\mathfrak{q} \in \operatorname{Sann}(M)$ we have the implication

$$\mathfrak{q} \subseteq \mathfrak{p} \quad\Longrightarrow\quad \mathfrak{q} = \mathfrak{p}$$

And we denote the set of all isolated primes of M by $\operatorname{Sann}(M)_*$. A prime annihilator ideal $\mathfrak{p} \in \operatorname{Sann}(M)$ of M that is *not* minimal is said to be an **embedded prime** of M.

(iii) Finally we define the **support** of M to be the set of prime ideals of R that contain an annihilator $\operatorname{ann}(x)$ of some element $x \in M$, formally that is the following set

$$\operatorname{Supp}(M) \;:=\; \{\, \mathfrak{p} \in \operatorname{Spec}(R) \mid \exists\, x \in M \;:\; \operatorname{ann}(x) \subseteq \mathfrak{p} \,\}$$

(5.6) Example: (viz. 1154)

(i) If $(R,+,\cdot)$ is an integral domain and $M \leq_{\mathrm{m}} R$ is a non-zero sub-module (i.e. ideal) of R, then the R-module M has a single annihilator ideal: the zero-ideal 0. That is we get

$$\mathrm{Anns}_R(M) \;=\; \mathrm{Sann}_R(M) \;=\; \{0\}$$

(ii) More generally: If $(R,+,\cdot)$ is a non-zero, commutative ring and M is a *torsion-free* R-module, which is $0 = \mathrm{tor}(M) = \{\, x \in M \mid \exists\, a \in R : a \neq 0 \text{ and } ax = 0 \,\}$, then we distinguish two cases:

$$\mathrm{Sann}(M) \;=\; \begin{cases} \{0\} & \text{if } M \neq 0 \text{ and } R \text{ is an integral domain} \\ \emptyset & \text{if } M = 0 \text{ or } R \text{ is not an integral domain} \end{cases}$$

(iii) If $(R,+,\cdot)$ is a commutative ring and M a simple, non-zero module [i.e. $P \leq_{\mathrm{m}} M$ implies $P = 0$ or $P = M$], then $\mathrm{ann}(M) = \{\, a \in R \mid \forall\, x \in M : ax = 0 \,\}$ is a maximal ideal and this ideal is the one and only annihilator ideal of M. That is we get

$$\mathrm{Anns}_R(M) \;=\; \mathrm{Sann}_R(M) \;=\; \{\, \mathrm{ann}(M) \,\}$$

(iv) If $(R,+,\cdot)$ is a commutative ring and $\mathfrak{p} \in \mathrm{Spec}(R)$ is a prime ideal of R then $\mathfrak{p}$ is the one and only annihilator of $R/\mathfrak{p}$ considered as an R-module. Formally that is

$$\mathrm{Anns}_R\left(R\Big/\mathfrak{p}\right) \;=\; \mathrm{Sann}_R\left(R\Big/\mathfrak{p}\right) \;=\; \{\, \mathfrak{p} \,\}$$

Nota Thereby $\mathfrak{a} \in \mathrm{Anns}_R(R/\mathfrak{a})$ is true for any proper ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$, $\mathfrak{a} \neq R$ of R, but for the converse inclusion the property $ab \in \mathfrak{p},\ b \notin \mathfrak{p} \implies a \in \mathfrak{p}$ of a prime ideal is required.

(v) Consider any commutative ring $(R,+,\cdot)$ and any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ and recall the notation $\mathbb{V}(\mathfrak{a})$ for the set of prime ideals containing $\mathfrak{a}$, i.e. $\mathbb{V}(\mathfrak{a}) := \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p} \,\}$. If we now regard $R/\mathfrak{a}$ as an R-module, then we obtain the identity

$$\mathrm{Supp}_R\left(R\Big/\mathfrak{a}\right) \;=\; \mathbb{V}(\mathfrak{a})$$

Nota in particular for $\mathfrak{a} = 0$ this yields: If we regard R as an R-module, then every prime ideal of R already is contained in the support $\mathrm{Supp}_R(R) = \mathrm{Spec}(R)$ of R.

(5.7) Lemma: (viz. 1155)
Let $(R,+,\cdot)$ be any commutative ring and M be an R-module, then the following statements are true:

(i) If N is another R-module, $\iota : M \to N$ a monomorphism of R-modules and $x \in M$, then we find that $\mathrm{ann}(\iota(x)) = \mathrm{ann}(x) \trianglelefteq_{\mathrm{i}} R$. In particular this yields the following inclusions

$$\begin{aligned} \mathrm{Anns}_R(M) &\subseteq \mathrm{Anns}_R(N) \\ \mathrm{Sann}_R(M) &\subseteq \mathrm{Sann}_R(N) \\ \mathrm{Supp}_R(M) &\subseteq \mathrm{Supp}_R(N) \end{aligned}$$

Nota In particular, if $M \cong_{\mathsf{m}} N$ are isomorphic, then the above inclusions even are equalities. In other words: Isomorphic modules share the same support and annihilator spectra.

(ii) If $\mathfrak{p} \in \operatorname{Spec}(R)$ is a prime ideal of R and $x \in M$ an element of M, then $\mathfrak{p}$ is the annihilator of x if and only if there is an isomorphism of R-modules between $R/\mathfrak{p}$ and $Rx \leq_{\mathsf{m}} M$. Formally

$$\mathfrak{p} = \operatorname{ann}(x) \iff {}^{R}\!\Big/_{\mathfrak{p}} \cong_{\mathsf{m}} Rx$$

Nota Thereby for any annihilator $\mathfrak{a} = \operatorname{ann}(x) \trianglelefteq_{\mathsf{i}} R$ we obtain the isomorphism $R/\mathfrak{a} \xrightarrow{\sim} Rx : a \mapsto ax$ of R-modules, but for the converse implication we require a prime ideal $\mathfrak{p}$ of R.

(iii) Recall the definition of the *annihilator* $\operatorname{ann}(M) = \{\, a \in R \mid \forall\, x \in M : ax = 0 \,\}$ of M and for some $\mathfrak{a} \subseteq R$ the notation $\mathbb{V}(\mathfrak{a}) = \{\, \mathfrak{p} \in \operatorname{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p} \,\}$. Then the following subsets of the spectrum of R are equal and this subset is called the *support* $\operatorname{Supp}(M)$ of M

$$\begin{aligned}\operatorname{Supp}(M) &= \mathbb{V}\big(\operatorname{ann}(M)\big)\\ &= \{\, \mathfrak{p} \in \operatorname{Spec}(R) \mid M_{\mathfrak{p}} \neq 0 \,\}\\ &= \{\, \mathfrak{p} \in \operatorname{Spec}(R) \mid \exists\, x \in M \,:\, \operatorname{ann}(x) \subseteq \mathfrak{p} \,\}\end{aligned}$$

(iv) Recall the definition $\operatorname{zd}(M) := \{\, a \in R \mid \exists\, x \in M : x \neq 0 \text{ and } ax = 0 \,\}$ of the set of *zero-divisors* of M. This set is the union of all annihilator ideals of M, in formal terms

$$\bigcup \operatorname{Anns}(M) = \operatorname{zd}(M)$$

(v) If $\mathfrak{a} \in \operatorname{Anns}(M)$ is a maximal annihilator ideal [that is for any $\mathfrak{b} \in \operatorname{Anns}(M)$ with $\mathfrak{a} \subseteq \mathfrak{b}$ we already get $\mathfrak{a} = \mathfrak{b}$] then $\mathfrak{a}$ already is a prime ideal and hence $\mathfrak{a} \in \operatorname{Sann}(M)$. Formally this is

$$\Big(\operatorname{Anns}(M)\Big)^{*} \subseteq \operatorname{Sann}(M)$$

(5.8) Proposition: (viz. 1156)
Let $(R, +, \cdot)$ be a commutative ring and M be an R-module. Then we find the following statements concerning the annihilator spectrum of M

(i) If $P \leq_{\mathsf{m}} M$ is a sub-module of M, then the annihilator spectrum of M is contained in the annihilator spectrum of P and M/P, that is

$$\operatorname{Sann}(P) \subseteq \operatorname{Sann}(M) \subseteq \operatorname{Sann}(P) \cup \operatorname{Sann}\Big({}^{M}\!\Big/_{P}\Big)$$

More generally: If $0 \to L \to M \to N \to 0$ is an exact chain of R-modules then we obtain the following inclusions of the annihilator spectra

$$\operatorname{Sann}(L) \subseteq \operatorname{Sann}(M) \subseteq \operatorname{Sann}(L) \cup \operatorname{Sann}(N)$$

(ii) Let $P_i \leq_{\mathsf{m}} M$ be an arbitrary ($i \in I$) family of sub-modules of M that cover M, i.e. $M = \bigcup_i P_i$. Then the annihilator spectrum of M is the union of the of all the annihilator spectra of the P_i

$$\mathsf{Sann}(M) \;=\; \bigcup_{i \in I} \mathsf{Sann}(P_i)$$

(iii) Let $P_i \leq_{\mathsf{m}} M$ be an arbitrary ($i \in I$) family of sub-modules of M such that $\bigcap_i P_i = 0$. Then the annihilator spectrum of M is contained in the union of the of all the annihilator spectra of M/P_i

$$\mathsf{Sann}(M) \;\subseteq\; \bigcup_{i \in I} \mathsf{Sann}\left(M \Big/ P_i\right)$$

(iv) Let M_i be an arbitrary ($i \in I$) family of R-modules M_i. Then the annihilator spectrum of the direct sum of the M_i is the union of all the annihilator spectra of the M_i

$$\mathsf{Sann}\left(\bigoplus_{i \in I} M_i\right) \;=\; \bigcup_{i \in I} \mathsf{Sann}(M_i)$$

(v) If $\mathfrak{p} \in \mathsf{Spec}(R)$ is a prime ideal of R, then $\mathfrak{p}$ is in the annihilator spectrum of M if and only if there is a monomorphism ι of R-modules, that maps $R/\mathfrak{p}$ into M, that is

$$\mathfrak{p} \in \mathsf{Sann}(M) \iff \exists\, \iota : R \Big/ \mathfrak{p} \hookrightarrow M$$

(vi) If R is a non-zero, noetherian ring, then the annihilator spectrum of M is empty, if and only if M is the zero module, that is

$$\mathsf{Sann}(M) = \emptyset \iff M = 0$$

(vii) Recall $\mathsf{zd}(M) := \{\, a \in R \mid \exists\, x \in M : x \neq 0 \text{ and } ax = 0 \,\}$ and suppose $R \neq 0$ is non-zero, noetherian ring. Then $\mathsf{zd}(M)$ also is the union of all its associated prime ideals. Formally that is

$$\bigcup \mathsf{Sann}(M) \;=\; \mathsf{zd}(M) \;=\; \bigcup \mathsf{Anns}(M)$$

(viii) Let $\mathcal{S} \subseteq \mathsf{Sann}(M)$ be an arbitrary subset of the annihilator spectrum of M, then there is a sub-module $P \leq_{\mathsf{m}} M$ of M satisfying the properties

$$\begin{aligned} \mathsf{Sann}(P) &= \mathcal{S} \\ \mathsf{Sann}\left(M \Big/ P\right) \cap \mathsf{Sann}(P) &= \emptyset \\ \mathsf{Sann}(M) \setminus S &\subseteq \mathsf{Sann}\left(M \Big/ P\right) \end{aligned}$$

(5.9) Example:
If $(R, +, \cdot)$ is an integral domain and we consider R as an R-module, then for any $a \in R$ with $a \neq 0$ we have $\mathsf{ann}(a) = 0$ and thereby 0 is the only element of the annihliator spectrum

$$\mathsf{Sann}(R) \;=\; \{0\}$$

If R is any commutative ring and $p \in R$ is prime let us consider R/pR as an R-module. Then $a \in \operatorname{ann}(b + pR)$ is equivalent to $ab \in pR$. But as p is prime and $b \notin pR$ this means $a \in pR$. Hence for any $b + pR \neq 0 + pR$ we get

$$\begin{aligned} \operatorname{ann}(b + pR) &= pR \\ \operatorname{Sann}\left(R \Big/ pR\right) &= \{\, pR \,\} \end{aligned}$$

This example illustrates that the quotient module M/P may have annihilators that the base module M did not. In other words the inclusions in (i) above may be strict and need not be equalities

$$\operatorname{Sann}(R) \;=\; \{0\} \;\subset\; \{\, 0,\, pR \,\} \;=\; \operatorname{Sann}(pR) \cup \operatorname{Sann}\left(R \Big/ pR\right)$$

(5.10) Example:
Proposition (5.8.(vi)) is surprisingly strong and widely used. Alas it is untrue in the non-noetherian case and in fact this is the main reason, why the later theorems require the noetherian property. As a counter-example regard the polynomial ring in infinitely many variables $R := \mathbb{Z}[t_1, t_2, t_3, \dots]$ and pick up the following ideal in R

$$\mathfrak{a} \;:=\; \langle t_1^2,\, t_2^2,\, t_3^2,\, \dots \rangle_{\mathrm{i}}$$

That is $\mathfrak{a}$ is generated by the squares t_i^2 of the variables t_i. Then we will see, that the R-module $M := R/\mathfrak{a}$ does not have a single associated prime ideal and thereby

$$\operatorname{Sann}_R\left(R \Big/ \mathfrak{a}\right) \;=\; \emptyset$$

Prob consider any $x = f + \mathfrak{a} \in M$ with $x \neq 0$. We will prove that $\operatorname{ann}(x)$ is *not* prime: By definition $\operatorname{ann}(x) = \{\, g \in R \mid gx = 0 \,\} = \{\, g \in R \mid gf \in \mathfrak{a} \,\}$. Because of $x \neq 0$ we have $f \notin \mathfrak{a}$. As $f \in R$ only has finitely many summands there is some $n \in \mathbb{N}$ such that $f \in \mathbb{Z}[t_1, \dots, t_n]$. As $t_{n+1}^2 \in \mathfrak{a}$ we have $t_{n+1}^2 f \in \mathfrak{a}$ but neither t_{n+1} nor f are elements of $\mathfrak{a}$. Hence $\operatorname{ann}(x)$ is not a prime ideal and as $x \neq 0$ has been arbitrary this means $R/\mathfrak{a}$ does not have a single associated prime ideal.

(5.11) Example: (viz. 1162)

(i) Let $(R, +, \cdot)$ be a PID and M be a non-zero finitely generated R-module, such that $M = M(p)$ for some prime $p \in R$. Then pR is the one and only associated prime ideal of M, that is

$$\operatorname{Sann}(M) \;=\; \{\, pR \,\}$$

(ii) If $(R, +, \cdot)$ is a PID and $a \in R$ with $a \neq 0$, then the associated prime ideals of R/aR are precisely those pR where $p \in R$ is a prime divisor of a. Formally that is

$$\operatorname{Sann}_R\left(R \Big/ aR\right) \;=\; \{\, pR \mid p \in R \text{ prime}, \, p \mid a \,\}$$

(5.12) Proposition: (viz. 1159)
Let $(R,+,\cdot)$ be a commutative ring, $U \subseteq R$ be a multiplicatively closed set and M be an R-module. We regard $U^{-1}M$ as an $U^{-1}R$-module and thereby obtain the following properties:

(i) If $\mathfrak{p} = \mathrm{ann}(x) \in \mathrm{Sann}(M)$ is a prime annihilator (of some $0 \neq x \in M$) such that $\mathfrak{p} \cap U = \emptyset$, then the annihilator of $x/1 \in U^{-1}M$ also is a prime ideal, namely we get

$$U^{-1}\mathrm{ann}(x) \;=\; \mathrm{ann}\left(\frac{x}{1}\right) \;\in\; \mathrm{Sann}_{U^{-1}R}\big(U^{-1}M\big)$$

(ii) Thereby $\mathfrak{p} \mapsto U^{-1}\mathfrak{p}$ is an injective map from the annihilator spectrum of M into the annihilator spectrum of $U^{-1}M$. And if R is a noetherian ring, then this map even is bijective, that is

$$\{\,\mathfrak{p} \in \mathrm{Sann}_R(M) \mid \mathfrak{p} \cap U = \emptyset\,\} \;\longleftrightarrow\; \mathrm{Sann}_{U^{-1}R}\big(U^{-1}M\big) \;:\; \mathfrak{p} \mapsto U^{-1}\mathfrak{p}$$

(iii) The surjectivity in (ii) is due to: If $\mathfrak{p} \in \mathrm{Spec}(R)$ is a finitely generated prime ideal of R, such that $\mathfrak{p} \cap U = \emptyset$ and $U^{-1}\mathfrak{p} \in \mathrm{Sann}(U^{-1}M)$, then $\mathfrak{p} \in \mathrm{Sann}(M)$ is the annihilator of some element of M.

(iv) Let R be a noetherian ring and $\mathcal{S}$ be the subset of all prime annihilator ideals of M, that do not meet U. That is $\mathcal{S} := \{\,\mathfrak{p} \in \mathrm{Sann}(M) \mid \mathfrak{p} \cap U = \emptyset\,\}$. Then there is precisely one sub-module $P \leq_{\mathfrak{m}} M$ of M that satisfies $\mathrm{Sann}(P) = \mathrm{Sann}(M) \setminus \mathcal{S}$ and $\mathrm{Sann}(P) \cap \mathrm{Sann}(M/P) = \emptyset$ and this is the kernel of the canonical homomorphism from M to $U^{-1}M$

$$P \;=\; \mathrm{kn}\left(M \to U^{-1}M \;:\; x \mapsto \frac{x}{1}\right)$$

(5.13) Corollary: (viz. 1161)
Let $(R,+,\cdot)$ be a non-zero, noetherian ring and M be any R-module. If $\mathfrak{p} \in \mathrm{Supp}(M)$ is any ideal in the support of M, then there is an associated prime ideal $\mathfrak{a} \in \mathrm{Sann}(M)$ such that $\mathfrak{a} \subseteq \mathfrak{p}$. From this property we see, that $\mathrm{Sann}(M)$ is contained in $\mathrm{Supp}(M)$ and that the minimal elements of these sets coincide. In particular the intersections of all associated prime ideals resp. of all prime ideals in the support of M yield the same result. Altogether this is

$$\begin{aligned} \mathrm{Sann}(M) &\subseteq \mathrm{Supp}(M) \\ \bigcap \mathrm{Sann}(M) &= \bigcap \mathrm{Supp}(M) \\ \big(\mathrm{Sann}(M)\big)_* &= \big(\mathrm{Supp}(M)\big)_* \end{aligned}$$

(5.14) Theorem: (viz. 1163) **Noetherian Filtration:**
Let $(R,+,\cdot)$ be a non-zero, noetherian ring and M be a finitely generated R-module. Then there are finitely many sub-modules $M_i \leq_{\mathfrak{m}} M$ (where $i \in 0 \ldots n$) and prime ideals $\mathfrak{p}_i \in \mathrm{Spec}(R)$ (where $i \in 1 \ldots n$) such that the M_i and $\mathfrak{p}_i$ combine to yield the follwoing two properties

(1) $0 = M_0 \subset M_1 \subset \ldots \subset M_n = M$

(2) for any $i \in 1 \ldots n$ we have an isomophy of the form $M_i \big/ M_{i-1} \cong_{\mathfrak{m}} R \big/ \mathfrak{p}_i$

Thereby $n \geq \operatorname{rank}(M)$ and the annihilator spectrum of M is contained in the set of ideals of $\mathfrak{p}_1$ to $\mathfrak{p}_n$ which in turn is contained in the support of M. In particular $\operatorname{Sann}(M)$ is finite and we have the inclusions

$$\operatorname{Sann}(M) \quad \subseteq \quad \{\, \mathfrak{p}_1, \ldots, \mathfrak{p}_n \,\} \quad \subseteq \quad \operatorname{Supp}(M)$$

(5.15) Remark:
Let us regard $M = \mathbb{Z}$ as an $R = \mathbb{Z}$-module, for example. We have $\operatorname{Sann}(\mathbb{Z}) = \{0\}$, as $\mathbb{Z}$ is an integral domain and $\operatorname{Supp}(\mathbb{Z}) = \operatorname{Spec}(\mathbb{Z})$ is a given, by (5.6.(iv)). Obviously $0 \subset \mathbb{Z}$ is a noetherian filtration using $\mathfrak{p}_1 = 0$. But we also find a different noetherian filtration $0 \subset 5\mathbb{Z} \subset \mathbb{Z}$. Here we have $\mathfrak{p}_2 = 5\mathbb{Z}$ and $\mathfrak{p}_1 = 0 \trianglelefteq_{\mathfrak{i}} \mathbb{Z}$, which is legit, as $5\mathbb{Z}/0 \cong_{\mathfrak{m}} \mathbb{Z}/0$ are isomorphic, as modules. From this example we can glean a few limitations of this method

- The inclusions $\operatorname{Sann}(M) \subset \{\, \mathfrak{p}_1, \ldots, \mathfrak{p}_n \,\} \subset \operatorname{Supp}(M)$ may both be strict.
- The length n of the filtration is *not* uniquely determined and may well exceed the rank of M, as an R-module. However we also see $\operatorname{rank}(M) \leq \#\operatorname{Supp}(M)$.
- The support $\operatorname{Supp}(M)$ may contain infinitely many elements, even for rank 1 modules over a PID.

(5.16) Corollary: (viz. 1164)
Let $(R, +, \cdot)$ be a non-zero noetherian ring, $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ be an ideal in R and M be a non-zero, finitely generated R-module. Then we obtain the following three sets of equivalences

(i) For any $x \in M$ let us denote $\mathfrak{a}x := \{\, ax \mid a \in \mathfrak{a} \,\}$, then the following four statements are equivalent

 (a) $\mathfrak{a} \subseteq \operatorname{zd}(M)$
 (b) $\exists\, \mathfrak{p} \in \operatorname{Sann}(M) \,:\, \mathfrak{a} \subseteq \mathfrak{p}$
 (c) $\exists\, x \in M \,:\, x \neq 0$ and $\mathfrak{a}x = \{0\}$
 (d) $\forall\, a \in \mathfrak{a}\ \exists\, x \in M \,:\, x \neq 0$ and $ax = 0$

(ii) The following three statements are equivalent, as well

 (a) $\mathfrak{a} \subseteq \bigcap \operatorname{Sann}(M)$
 (b) $\operatorname{Sann}(M) \subseteq \mathbb{V}(\mathfrak{a})$
 (c) $\exists\, n \in \mathbb{N} \,:\, \mathfrak{a}^n M = 0$

(iii) For any $a \in R$ let us denote the *homothety* $\lambda_a : M \to M : x \mapsto ax$. To say that λ_a is *nilpotent* means $\lambda_a^n = 0 \in \operatorname{end}(M)$ for some $n \in \mathbb{N}$. If now $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$ is a prime ideal of R, then the following five statements are equivalent

 (a) $\operatorname{Sann}(M) = \{\, \mathfrak{p} \,\}$
 (b) $\forall\, x \in M$ we have: $x \neq 0 \implies \sqrt{\operatorname{ann}(x)} = \mathfrak{p}$
 (c) $\forall\, a \in R$ we have: λ_a is injective or nilpotent
 (d) $\forall\, a \in R$ we have: $a \in \operatorname{zd}(M) \iff \exists\, n \in \mathbb{N} \,:\, a^n M = 0$
 (e) $\forall\, a \in R$ we have: $a \in \operatorname{zd}(M) \iff \forall\, x \in M\ \exists\, n \in \mathbb{N} \,:\, a^n x = 0$

Nota that in this case we find $\mathfrak{p} = \{ a \in R \mid \lambda_a \text{ is nilpotent} \} = \{ a \in R \mid \exists n \in \mathbb{N} : a^n M = 0 \}$. And this set always is an ideal of R, but not necessarily prime, in general.

(5.17) Definition:
Let $(R, +, \cdot)$ be a commutative ring, $\mathfrak{p} \in \operatorname{Spec}(R)$ be a prime ideal of R and M be an R-module. Then we say that M is **$\mathfrak{p}$-primary**, iff $\mathfrak{p}$ is the one and only associated prime of M, formally iff

$$\operatorname{Sann}(M) \;=\; \{ \mathfrak{p} \}$$

And if $P \leq_{\mathfrak{m}} M$ is a sub-module of M then P is said to be **$\mathfrak{p}$-coprimary in** M iff the quotient module M/P is $\mathfrak{p}$-primary, that is iff $\mathfrak{p}$ is the one and only associated prime ideal of M/P

$$\operatorname{Sann}\left(M \Big/ P \right) \;=\; \{ \mathfrak{p} \}$$

Finally M is said to be **primary**, iff M is $\mathfrak{p}$-primary for some prime ideal $\mathfrak{p} \in \operatorname{Spec}(M)$. Likewise P is said to be **coprimary in** M, if L is coprimary in M for some prime ideal $\mathfrak{p} \in \operatorname{Spec}(M)$.

Nota if R is non-zero, noetherian and M is non-zero, finitely generated, then corollary (5.16.(iii)) boasts a rather extensive list of equivalences to M being a $\mathfrak{p}$-primary module.

(5.18) Example: (viz. 1166)
Let $(R, +, \cdot)$ be a non-zero, noetherian ring and $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ be an ideal of R, with $\mathfrak{a} \neq R$. Denote $\mathfrak{p} := \sqrt{\mathfrak{a}}$ then $\mathfrak{a}$ is primary, as an ideal of R if and only if $\mathfrak{a}$ is $\mathfrak{p}$-coprimary in R, as an R-module. Explicitly this is

$$\mathfrak{a} \text{ is a primary ideal} \quad\Longleftrightarrow\quad \operatorname{Sann}_R\left(R \Big/ \mathfrak{a} \right) \;=\; \{ \mathfrak{p} \}$$

(5.19) Remark:
This example is the reason why most textbooks (including Bourbaki) say that $P \leq_{\mathfrak{m}} M$ is $\mathfrak{p}$-primary, iff P is $\mathfrak{p}$-coprimary (in our sense). This is a problematic notion however, as it depends not only on P, but also on the parent module M. For this reason we follow the same lines, the CRing project does, hoping to further a modernization of mathematical nomenclature. Also we would like to thank the authors of the CRing project [https://math.uchicago.edu/∼amathew/cr.html] for sharing their insights. In classical literature what we call $\mathfrak{p}$-primary remains undefined or is called $\mathfrak{p}$-coprimary. Effectively the notions of primary and coprimary are interchanged in these textbooks.

(5.20) Proposition: (viz. 1166)
Let $(R, +, \cdot)$ be a commutative ring, $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$ be a prime ideal and M be an R-module. Also let P and $P_1, \ldots, P_n \leq_{\mathfrak{m}} M$ be sub-modules of M, then the following statements are true:

(i) If R is non-zero and noetherian, M is finitely generated and $P \neq 0$ is non-zero, then we get the implication: If M is $\mathfrak{p}$-primary, then P is $\mathfrak{p}$-primary, too.

(ii) If for any $k \in 1 \ldots n$ the sub-module P_k is $\mathfrak{p}$-primary (all to the same prime ideal $\mathfrak{p}$), then the sum $P_1 + \cdots + P_n \leq_{\mathfrak{m}} M$ of these sub-modules is $\mathfrak{p}$-primary, too.

(iii) If R is non-zero and noetherian, M is finitely generated and for any $k \in 1 \dots n$ the sub-module P_k of M is $\mathfrak{p}$-coprimary in M (all to the same prime ideal $\mathfrak{p}$), then the intersection $P_1 \cap \dots \cap P_n \leq_{\mathfrak{m}} M$ of these sub-modules is $\mathfrak{p}$-coprimary in M, too.

(iv) Consider a short exact chain $0 \to L \to M \to N \to 0$ of R-modules, then we get the following implication: If both L and N are $\mathfrak{p}$-primary, then M is $\mathfrak{p}$-primary, too.

(5.21) Definition:
Let $(R, +, \cdot)$ be a commutative ring and M be an R-module. Also let $P, Q \leq_{\mathfrak{m}} M$ be any two sub-modules of M, then we define the following notions:

(i) A sub-module $L \leq_{\mathfrak{m}} M$ is said to be **prime** iff any non-zero sub-module P of L has precisely the same annihilators, formally that is the following implication for any sub-module $P \leq_{\mathfrak{m}} L$:

$$P \neq 0 \implies \operatorname{ann}(P) = \operatorname{ann}(L)$$

(ii) A sub-module $P \leq_{\mathfrak{m}} M$ is said to be **irreducible**, iff it is not the intersection of two sub-modules strictly containing P. Formally that is iff for all sub-modules $U, V \leq_{\mathfrak{m}} M$ we get

$$P = U \cap V \implies P = U \text{ or } P = V$$

(5.22) Theorem: (viz. 1167)

(i) If $(R, +, \cdot)$ is a non-zero, noetherian ring, M is a finitely generated R-module and $P \leq_{\mathfrak{m}} M$ is a proper, irreducible sub-module of M then P already is coprimary in M. More explicitly, that is

$$P \neq M,\ P \text{ irreducible} \implies \exists\, \mathfrak{p} \in \operatorname{Spec}(R) : \operatorname{Sann}\left(M \Big/ P\right) = \{\mathfrak{p}\}$$

(ii) Let $(R, +, \cdot)$ be a commutative ring, M be a noetherian R-module and $L \leq_{\mathfrak{m}} M$ be a sub-module of M. Then L admits an **irreducible decomposition**, i.e. there are finitely many sub-modules $P_1, \dots, P_s \leq_{\mathfrak{m}} M$ satisfying the following two properties

(1) $L = P_1 \cap \dots \cap P_s$

(2) P_j is irreducible, for any $j \in 1 \dots s$

(iii) Let $(R, +, \cdot)$ be a non-zero, noetherian ring, M be a finitely generated R-module and $L \leq_{\mathfrak{m}} M$ be any sub-module of M. Then L admits a **reduced primary decomposition**, that is there is some $1 \leq s \in \mathbb{N}$ and for any $i \in 1 \dots s$ there are a sub-module $P_i \leq_{\mathfrak{m}} M$ and a prime ideal $\mathfrak{p}_i \in \operatorname{Spec}(R)$, such that the following four properties hold true:

(1) $L = P_1 \cap \dots \cap P_s$

(2) $\forall\, i \in 1 \dots s$ we get $L \neq \bigcap_{j \neq i} P_j$

(3) $\forall\, i \in 1 \dots s$ we get P_i is $\mathfrak{p}_i$-coprimary in M

(4) $\forall\, i, j \in 1 \dots s$ we get $\mathfrak{p}_i = \mathfrak{p}_j \implies i = j$

Nota hereby properties (1) and (3) constitute a *primary decomposition* of L. And in presence of (2) and (4) we speak of a *reduced* decomposition.

(iv) We continue with (iii): If $U \subseteq R$ is a multiplicatively closed set, then we regard $U^{-1}L$ and $U^{-1}P_i$ as $U^{-1}R$-sub-modules of $U^{-1}M$. And thereby $\{ U^{-1}P_i \mid i \in 1 \dots s, \mathfrak{p}_i \cap U = \emptyset \}$ is a reduced primary decomposition of $U^{-1}L$ where $U^{-1}P_i$ belongs to the prime ideal $U^{-1}\mathfrak{p}_i \in \operatorname{Spec}(U^{-1}R)$.

Nota this decomposition has some further useful properties: For any $i \in 1 \dots s$ with $\mathfrak{p}_i \cap U \neq \emptyset$ we even find $U^{-1}P_i = U^{-1}M$ and if $\mathfrak{p}_i \cap U = \emptyset$ we get $P_i = \kappa^{-1}(U^{-1}P_i)$, which explicitly reads as

$$P_i \;=\; \{ x \in M \mid \exists\, u \in U \,:\, ux \in P_i \}$$

(5.23) Corollary: (viz. 1170) **Primary Decomposition:**
Let $(R, +, \cdot)$ be a non-zero, noetherian ring, M be a finitely generated R-module and $L \leq_{\mathfrak{m}} M$ be any sub-module of M. Also let $P_1, \dots, P_s$ be a reduced primary decomposition of L and for $i \in 1 \dots s$ denote the prime ideal associated to M/P_i by $\mathfrak{p}_i$. This is (5.22.(iii)). Then we find further properties:

(i) The following map is an injective homomorphism of R-modules. Thereby, as any P_i is $\mathfrak{p}_i$-coprimary, we have $\operatorname{Sann}(M/P_i) = \mathfrak{p}_i$ for any $i \in 1 \dots n$

$$M \big/ L \hookrightarrow \bigoplus_{i=1}^{s} M \big/ P_i \;:\; x + L \mapsto (x + P_i)$$

(ii) The prime ideals $\mathfrak{p}_i$ are precisely the associated primes M/L. In particular the set $\{ \mathfrak{p}_1, \dots, \mathfrak{p}_s \}$ of the prime ideals occuring in the decomposition is uniquely determined

$$\operatorname{Sann}\left(M \big/ L \right) \;=\; \{ \mathfrak{p}_1, \dots, \mathfrak{p}_s \}$$

(iii) If $\mathfrak{p}_k$ is a minimal element of $\{ \mathfrak{p}_1, \dots, \mathfrak{p}_s \}$ [i.e. there is no $i \in 1 \dots s$ such that $\mathfrak{p}_i \subset \mathfrak{p}_k$] then P_k is uniquely determined, as it is given to be the following sub-module of M

$$P_k \;=\; \{ x \in M \mid \exists\, u \in R \setminus \mathfrak{p}_k \,:\, ux \in L \}$$

$$P_k \big/ L \;=\; \operatorname{kn}\left(M \big/ L \to \left(M \big/ L \right)_{\mathfrak{p}_k} \;:\; x + L \mapsto \frac{x + L}{1} \right)$$

(5.24) Example:

(i) Consider $R = \mathbb{Z}$ and $M = \mathbb{Z} \oplus \mathbb{Z}_7 \oplus \mathbb{Z}_{25}$, then M has the following associated prime ideals $\mathfrak{p}_k$ and corresponding $\mathfrak{p}_k$-coprimary ideals in M, given in the table below

k	$\mathfrak{p}_k = \operatorname{ann}(x)$	x	P_k
0	0	$(1, 0 + 7\mathbb{Z}, 0 + 25\mathbb{Z})$	$0 \oplus \mathbb{Z}_7 \oplus \mathbb{Z}_{25}$
1	$7\mathbb{Z}$	$(0, 1 + 7\mathbb{Z}, 0 + 25\mathbb{Z})$	$\mathbb{Z} \oplus 0 \oplus \mathbb{Z}_{25}$
2	$5\mathbb{Z}$	$(0, 0 + 7\mathbb{Z}, 5 + 25\mathbb{Z})$	$\mathbb{Z} \oplus \mathbb{Z}_7 \oplus 0$

Clearly $M = P_0 \cap P_1 \cap P_2 = 0$ is a reduced primary decomposition of the zero-module $L = 0$ is M. Note that $\{ \mathfrak{p}_0, \mathfrak{p}_1, \mathfrak{p}_2 \}$ is uniquely determined by $\mathrm{Sann}(M)$. Also, as $\mathfrak{p}_0 = 0$ is minimal, $\mathcal{P}_0$ also is uniquely determined, in fact $P_0 = \mathrm{tor}(M)$. Yet P_1 and P_2 are *not* uniquely determined, e.g. we could replace P_2 by P_2' where we let

$$P_2' \ := \ \{ (k, k + 7\mathbb{Z}, 0 + 25\mathbb{Z}) \mid k \in \mathbb{Z} \}$$

(ii) Again for $R = \mathbb{Z}$ we take a look, at $M = \mathbb{Z}^2 \oplus \mathbb{Z}_5 \oplus \mathbb{Z}_{25}$. Then M has two associated primes $\mathfrak{p}_0$ and $\mathfrak{p}_1$, only. As above, the following table also gives the corresponding $\mathfrak{p}_k$-coprimary ideals in M

k	$\mathfrak{p}_k = \mathrm{ann}(x)$	x	P_k
0	0	$(1, 0, 0 + 5\mathbb{Z}, 0 + 25\mathbb{Z})$	$0^2 \oplus \mathbb{Z}_5 \oplus \mathbb{Z}_{25}$
1	$5\mathbb{Z}$	$(0, 0, 0 + 5\mathbb{Z}, 5 + 25\mathbb{Z})$	$\mathbb{Z}^2 \oplus 0 \oplus 0$

Then $M/P_0 \ \cong_{\mathsf{m}} \ \mathbb{Z}^2$ which is torsion-free such that $\mathfrak{p}_0 = 0$ is the one and only associated prime of M/P_0. And $M/P_1 \ \cong_{\mathsf{m}} \ \mathbb{Z}_5 \oplus \mathbb{Z}_{25}$, which is annihilated by $5 \in \mathbb{Z}$ such that M/P_1 is $\mathfrak{p}_1$-coprimary in M where $\mathfrak{p}_1 = 5\mathbb{Z}$. We hence see, that the number s of coprimary components occuring in the decomposition be fewer than the rank of M.

(5.25) Example:
Generally if $(M, +, \cdot)$ is a PID, $s \in \mathbb{N}$ and for any $j \in 1 \ldots s$ let $p(j) \in R$ be a prime element of R, such that the $p(j)$ are non-associated, that is for any $j, k \in 1 \ldots s$ we suppose $p(j) \approx q(k) \implies j = k$. Also for any $j \in 1 \ldots s$ let $1 \leq I(j) \in \mathbb{N}$ and for $i \in 1 \ldots I(j)$ let $1 \geq n(i, j) \in \mathbb{N}$. Then we regard the R-module [the torsion part of *any* finitely generated R-module can be written in this form, by (5.32.(v))]

$$M \ := \ \bigoplus_{j=1}^{s} \bigoplus_{i=1}^{I(j)} R \Big/ p(j)^{n(i,j)} R$$

We have already seen in (5.4) that for any $k \in 1 \ldots s$ the p_k-primary component of M is given to be the following [we have also seen $M(q) = 0$ for any $q \in R$ prime, that is *not* associated to any of the p_k]

$$M(p_k) \ = \ \bigoplus_{i=1}^{I(k)} R \Big/ p(k)^{n(i,k)} R$$

In particular we find that $M = M(p_1) \oplus \cdots \oplus M(p_k)$ is the inner direct sum of $p_k R$-primary components, as we have seen $\mathrm{Sann}(M(p_k)) = \{ p_k R \}$ in (5.11.(i)). For any $k \in 1 \ldots s$ let us now denote

$$P_k \ := \ \widehat{M}_k \ = \ \bigoplus_{j \neq k} M(p_j)$$

Then $M/P_k \ \cong_{\mathsf{m}} \ M(p_k)$ and from this it is clear that we have found a reduced primary decomposition of the zero-sub-module $L = 0$ in M

$$P_1 \cap \cdots \cap P_s \ = \ 0$$

In particular (5.23) tells us that we have an embedding of the following form, [but as $M/P_k \cong_{\mathfrak{m}} M(p_k)$ again and $M = M(p_1) \oplus \cdots \oplus M(p_k)$ this even is an isomorphism in this case]

$$M = {}^{M}\big/_{L} \hookrightarrow \bigoplus_{j=1}^{s} {}^{M}\big/_{P_j} : x \mapsto (x + P_j)$$

As all the p_kR are minimal in $\{ p_jR \mid j \in 1 \ldots s \}$ here, the p_kR-coprimary components of M are uniquely determined. This becomes untrue, as soon, as we also gain 0 as an associated primary ideal of M, by adding a non-torsion part $N := \mathbb{Z}^f \oplus M$ to M. In this case

$$\mathrm{Sann}(N) = \{ 0, p_1R, \ldots, p_sR \}$$

so for convenience let $p_0 := 0 \in R$. We also have to modify all the P_k before, by adding $Q_k := \mathbb{Z}^f \oplus P_k$. If we also let $Q_0 := 0 \oplus M$, then Q_k is p_kR-coprimary in N, as $N/Q_0 \cong_{\mathfrak{m}} \mathbb{Z}^f$ and for any $k \in 1 \ldots s$ we still have $N/Q_k \cong_{\mathfrak{m}} M(p_k)$. Thus we have gained a reduced irreducible decomposition of 0 again

$$(0 \oplus M) \oplus \bigoplus_{j=1}^{s} {}^{\mathbb{Z}^f \oplus M}\big/_{\mathbb{Z}^f \oplus P_j} = 0 \leq_{\mathfrak{m}} \mathbb{Z}^f \oplus M$$

5.2 Invariant Factors

In this section we will present a complete classification of finitely generated modules over PIDs. Note that this encompasses finitely generated abelian groups, as these can be regarded as $\mathbb{Z}$-modules under the scalar multiplication $\mathbb{Z} \times G \to G : (k, g) \mapsto g^k$. So let us outline the ultimate goal of this section: First of all any finitely generated module M over a PID R can be decomposed into

$$M \quad \cong_{\mathsf{m}} \quad M \Big/ \mathsf{TOR}(M) \oplus \mathsf{TOR}(M)$$

This is due to the fact that $M/\mathsf{TOR}(M)$ is torsion-free and finitely generated and over a PID this implies that $M/\mathsf{TOR}(M)$ even is free. So the torsion-free part $M/\mathsf{TOR}(M)$ of M is free and hence of the form R^f for some $f \in \mathbb{N}$. It remains to study the torsion-part $\mathsf{TOR}(M)$. It will turn out, that this part is of the form

$$\mathsf{TOR}(M) \quad \cong_{\mathsf{m}} \quad \bigoplus_{i=1}^{r} R \Big/ d_i R$$

This is not so much of a surprise, as $R/\mathrm{ann}(x) \xrightarrow{\sim} Rx$ is true for any $x \in M$ and $\mathsf{TOR}(M)$ is finitely generated again. But if we do it right, we can arrange the *invariant factors* d_i in such a way, that they form an ascending chain under the division relation $d_1 \mid d_2$, $d_2 \mid d_3$ and so on until $d_{n-1} \mid d_n$. And it turns out that these d_i are unique up to associatedness.
We will also present two variations of this representation of M: By primary decomposition of the invariant factors and application of the Chinese remainder theorem, we also find a form using *elementary divisors*: That is there are (distinct) primes $p(j) \in R$ and powers $1 \leq n(i,j) \in \mathbb{N}$ such that the torsion-part is of the form

$$\mathsf{TOR}(M) \quad \cong_{\mathsf{m}} \quad \bigoplus_{j=1}^{s} \bigoplus_{i=1}^{I(j)} R \Big/ p(i)^{n(i,j)} R$$

It is this form from which we can also construct the primary decomposition of M, as we have already outlined in section 5.1, refer to (5.25) for details. But of course these external isomorphies define the inner structure of M. If M is a non-zero, finitely generated module over a PID, it can be written as an inner direct sum of cyclic sub-modules

$$M \quad = \quad \bigoplus_{i=1}^{n} Rm_i$$

such that $\mathrm{ann}(m_1) \supseteq \ldots \supseteq \mathrm{ann}(m_n)$. Thereby the chain of annihilators has the length $n = \mathrm{rank}(M)$ and is uniquely determined. This is another consequence of the invariant factor form. We will present a remark that describes in detail how to get from one form to the other.
Later on the chain of invariant ideals will play an important role in canonical form theory: If V is a finitely generated vector space over a field F and $\varphi : V \to V$ is linear, then V can be turned into an $F[t]$-module. But as $F[t]$ is a PID, we can decompose V into cyclic sub-modules and thereby study φ. But in order to get to that point we need some more tools, most notably the notion of a *primitive* element $p \in M$ and the *content* of an element $x \in M$.

(5.26) Definition: (viz. 1171)

(i) Let $(R,+,\cdot)$ be a commutative ring and M be an R-module. Then an element $p \in M$ is said to be **primitive** iff for any $x \in M$ and any $a \in R$ we get the implication

$$p = ax \implies a \in R^*$$

(ii) If $(R,+,\cdot)$ be a commutative ring, M is an R-module and $P \leq_{\mathsf{m}} M$ is a sub-module of M, then we recall the definition of the **hull** of P to be the set of all $x \in M$ that have a multiple in P, that is

$$\mathrm{Hull}(P) := \{\, x \in M \mid \exists\, a \in R : a \neq 0 \text{ and } ax \in P \,\}$$

If R is an integral domain, then $\mathrm{Hull}(P)$ is a sub-module of M that contains P and all torsion elements of M, i.e. we have $P + \mathrm{tor}(M) \subseteq \mathrm{Hull}(P) \leq_{\mathsf{m}} M$.

(iii) If $(R,+,\cdot)$ is an UFD and $M \neq 0$ is a non-zero free R-module with basis $\{\, m_i \mid i \in I \,\}$ then for any $x \in M$ we define the **content** of x to be the greatest common divisor of the coefficients of x

$$\mathrm{cont}(x) := \gcd\{\, a_i \mid i \in I \,\} \quad \text{where} \quad x = \sum_{i \in I} a_i m_i$$

Recall that thereby $c \in \mathrm{cont}(x)$ is equivalent, to $\mathrm{cont}(x) = cR^*$, as the greatest common divisor is is unique up to associatedness. And note that this is well defined, that is independent of the choice of the basis of M. If $\{\, n_i \mid i \in I \,\}$ is another basis of M and $x = \sum_i b_i n_i$ then we have $\gcd\{\, a_i \mid i \in I \,\} = \gcd\{\, b_i \mid i \in I \,\}$.

(5.27) Example:

(i) The 3-tuple $x = (4,6,0) \in \mathbb{Z}^3$ is not primitive, as it can be written as $x = 2p$ where $p = (2,3,0) \in \mathbb{Z}^3$. Clearly p is primitive, as we cannot pull out any common factor of the coefficients, as $1 \in \gcd\{\, 2,3,0 \,\}$. This example illustrates that p is primitive if and only if $\mathrm{cont}(p) = 1$, which we will prove next.

(ii) If F is a field and V is an F-vector space, then $p \in V$ is primitive if and only if $p \neq 0$ is non-zero.

Prob $0 \in V$ is not primitive, as $0 = 0x$ for any $x \in V$ and $0 \notin F^*$. Conversely if $p \neq 0$ then $p = ax$ implies $a \neq 0$ and hence $a \in F^*$. Admittedly this is somewhat artifical, but true nevertheless.

(iii) If R is a commutative ring and we regard $M = R$ as an R-module itself, then $p \in M$ is primitive, if and only if $p \in R^*$.

Prob clearly $p = p \cdot 1$ is generally true. But if p is primitive, this implies $p \in R^*$. And conversely if $p \in R^*$, then $p = ax$ yields $1 = (ax)p^{-1} = a(xp^{-1})$ such that $a \in R^*$.

(iv) If we regard $\mathbb{Q}$ as a $\mathbb{Z}$-module, then $\mathbb{Q}$ has no primitive elements at all, as always $u/v = 2(u/2v)$ but $2 \notin \mathbb{Z}^*$ is not a unit.

(5.28) Proposition: (viz. 1172)

(i) If $(R,+,\cdot)$ is a commutative ring, M is a noetherian R-module and $x \in M$ an element with $\mathrm{ann}(x) = 0$, then there is some primitive $p \in M$ and some $a \in R$ such that

$$x \;=\; ap$$

(ii) If $(R,+,\cdot)$ is an UFD and M a free R-module, then any $x \in M$ with $x \neq 0$ is primitive, if and only if $\mathrm{cont}(x) = 1$. Formally we find the equivalence of

$$x \text{ is primitive} \quad\Longleftrightarrow\quad 1 \in \mathrm{cont}(x)$$

In particular if we choose any $c \in \mathrm{cont}(x)$, then there is some primitive $p \in M$ such that $x \neq 0$ can be written in the following form

$$x \;=\; cp$$

(iii) If $(R,+,\cdot)$ is a PID, M is a free R-module and $p \in M$ is any fixed primitive element of M, then there is a basis $\{ m_i \mid i \in I \}$ of M that contains p, i.e. $p \in \{ m_i \mid i \in I \}$.

(iv) If $(R,+,\cdot)$ is a PID, M is free R-module and $P \leq_{\mathrm{m}} M$ is a finitely generated sub-module of M, then there are a basis $\mathcal{M} = \{ m_i \mid i \in I \}$ of M, a finite subset $\{ p_i \mid i \in 1 \ldots n \} \subseteq \mathcal{M}$ and a set of scalars $\{ d_i \mid i \in 1 \ldots n \} \subseteq R \setminus \{0\}$ that satisfy

(1) $\{ d_i p_i \mid i \in 1 \ldots n \}$ is a basis of P

(2) for any $i \in 2 \ldots n$ we have $d_{i-1} \mid d_i$

(5.29) Remark:

- Let us sketch the proof of (5.28.(iv)) how to find the invariant factors d_i. This is done iteratively, by the rank of P: If $P = 0$ then $n = 0$ and hence there are none. If $P \neq 0$, let $M_1 := M$ and $P_1 := P$ and consider the following set of ideals of R

$$\mathcal{A}_1 \;:=\; \{ \mathrm{cont}(x)R \mid x \in P_1,\, x \neq 0 \}$$

Thereby $\mathrm{cont}(x)R$ is the ideal generated by $\mathrm{cont}(x) \subseteq R$, but this is equivalent to $\mathrm{cont}(x)R = cR$ for an arbitrary $c \in \mathrm{cont}(x)$.

- As R is noetherian (even a PID) the set $\mathcal{A}_1$ of ideals has a maximal element $\mathrm{cont}(x_1)R \in \mathcal{A}_1^*$. Let $d_1 := \mathrm{cont}(x_1)$ and $x_1 = d_1 p_1$ for some primitive $p_1 \in M$. Then we find a basis $\mathcal{M}_1$ of M_1 containing p_1. If we let $\mathcal{M}_2 := \mathcal{M}_1 \setminus \{ p_1 \}$, $M_2 := \mathrm{Lh}(\mathcal{M}_2)$ and $P_2 := P_1 \cap M_2$ then

$$P_1 \;=\; Rx_1 \oplus P_2$$

- So we can commence with P_2 in the same way: Define $\mathcal{A}_2$, pick some $x_2 \in P_2$ such that $\mathrm{cont}(x_2)R$ is maximal in $\mathcal{A}_2$, write $x_2 = d_2 p_2$ and so on until $P_{n+1} = 0$. By construction $\{ p_1, \ldots, p_n \} \cup \mathcal{M}_{n+1}$ is a basis of M and $\{ x_1, \ldots, x_n \} = \{ d_1 p_1, \ldots, d_n p_n \}$ is a basis of P. And the respective maximality of $\mathrm{cont}(x_i)R \in \mathcal{A}_i$ ensures $d_{i-1} \mid d_i$.

(5.30) Example:
The following example will illustrate (5.28.(iv)): As the base module we choose $M := \mathbb{Z}^3$. Now let $x_1 := (2,4,0)$, $x_2 := (2,-2,0)$ and $x_3 := (4,20,0)$. Let $P := \mathrm{Lh}\{\, x_1, x_2, x_3 \,\}$ be the sub-module of M generated by x_1 to x_3. In other words P is given to be

$$P \;:=\; \mathrm{im}\begin{pmatrix} 2 & 2 & 4 \\ 4 & -2 & 20 \\ 0 & 0 & 0 \end{pmatrix} \;\leq_{\mathrm{m}}\; \mathbb{Z}^3$$

Clearly $\mathrm{cont}(x_1) = \mathrm{cont}(x_2) = 2$ and $\mathrm{cont}(x_3) = 4$. Thus $2\mathbb{Z}$ is the maximal ideal of $\mathcal{A}_1$ and we take $d_1 := 2$. In general there may be several ideals maximal in $\mathcal{A}_1$. In this case the natural choice is x_1 for an element with maximal content such that $p_1 = (1,2,0)$, as $d_1 p_1 = x_1$. We can append $\{\, p_1 \,\}$ to a basis $\{\, p_1, m_2, m_3 \,\}$ of M by taking $m_2 := (0,1,0)$ and $m_3 := (0,0,1)$. Then $M_2 = 0 \oplus \mathbb{Z}^2$ and

$$P_2 \;=\; P_1 \cap M_2 \;=\; \{\, (0, 4a - 2b + 20c, 0) \mid 2a + 2b + 4c = 0 \,\}$$

where a, b and $c \in \mathbb{Z}$. The condition $2a + 2b + 4c = 0$ can be rewritten as $b = -a - 2c$ and inserting this into P_2 we find the following presentation of P_2

$$P_2 \;=\; \{\, (0, 6(a + 4c), 0) \mid a, c \in \mathbb{Z} \,\} \;=\; 0 \oplus 6\mathbb{Z} \oplus 0$$

That is $d_2 = 6$ and $p_2 = (0,1,0) = m_2$. In this lucky case $\{\, p_2, m_3 \,\}$ is a basis of M_2 again such that $\{\, d_2 p_2 \,\}$ is a basis of P_2. Since $M_3 = 0^2 \oplus \mathbb{Z}$ and $P_3 = P_2 \cap M_3 = 0$ we are done. Altogether we have found a basis $\{\, p_1, p_2, m_3 \,\}$ and $\{\, d_1, d_2 \,\}$ such that $\{\, d_1 p_1, d_2 p_2 \,\}$ is a basis of P. Hereby $d_1 p_1 = (2,4,0) = x_1$ and $d_2 p_2 = (0,6,0)$.

By now we have all the ingredients needed for the proof of the classification of finitely generated modules over PIDs. Note however that the sequel of proves does not match the order in which the theorems are given. To us the invariant factor form seems to be the natural choice, but there are direct approaches to the forms of invariant ideals and elementary divisors, as well.
So let us first study modules that are in invariant factor form - these are well-behaved even over UFDs. After that we will prove that over a PID any finitely generated module is isomorphic to such a module. And the other two forms will be derived from the invariant factor form.

(5.31) Proposition: (viz. 1175)
Let $(R, +, \cdot)$ be an integral domain, f, $r \in \mathbb{N}$ and $\{\, d_1, \ldots, d_r \,\} \subseteq R^\bullet$ be non-zero, non-unit elements of the base ring such that for any $i \in 2 \ldots r$ we have the divisibility condition $d_{i-1} \mid d_i$. Then we get the following statements concerning the R-module

$$M \;:=\; R^f \oplus T \quad \text{where} \quad T \;:=\; \bigoplus_{i=1}^{r} R \Big/ d_i R$$

(i) $\mathrm{free}(M) \;=\; f$

(ii) $\mathrm{ann}(T) \;=\; d_r R$

(iii) $\mathrm{TOR}(M) \;=\; \{0\}^f \oplus T$

(iv) M is free if and only if $r = 0$

(v) M is a torsion-module if and only if $f = 0$

And if R even is an UFD we can also control the rank of this module M, as we find the equalities of

(vi) $\mathrm{rank}(T) \;=\; r$

(vii) $\mathrm{rank}(M) \;=\; f + r$

(5.32) Theorem: (viz. 1177)
Let $(R, +, \cdot)$ be a PID and M a finitely generated module over R. Then we find the following statements:

(i) **Invariant Ideals:** If $M \neq 0$ is non-zero and $n := \mathrm{rank}(M) < \infty$ is finite, then there are some $m_1, \ldots, m_n \in M \setminus \{0\}$ such that M is the inner direct sum

$$M \;=\; Rm_1 \oplus \cdots \oplus Rm_n$$

and $\mathrm{ann}(m_1) \supseteq \mathrm{ann}(m_2) \supseteq \ldots \supseteq \mathrm{ann}(m_n) = \mathrm{ann}(M)$. This descending chain of ideals in R is said to be the chain of *invariant ideals* of M. And in this case for any $i \in 2 \ldots n$ we also get

$$\mathrm{ann}(m_{i-1}) \;=\; \mathrm{ann}\left(M \Big/ Rm_i + \cdots + Rm_n \right)$$

(ii) The chain of invariant ideals of M is uniquely determined, that is: Suppose $m, n \in \mathbb{N}$ and let $p_1, \ldots, p_m$ and $q_1, \ldots, q_n \in M \setminus \{0\}$ be some vectors, such that M is the inner direct sums

$$\bigoplus_{i=1}^{m} Rp_i \;=\; M \;=\; \bigoplus_{j=1}^{n} Rq_j$$

and $\mathrm{ann}(p_1) \supseteq \ldots \supseteq \mathrm{ann}(p_m)$ and $\mathrm{ann}(q_1) \supseteq \ldots \supseteq \mathrm{ann}(q_n)$. Then we already have $m = n$ and for any $i \in 1 \ldots n$ we also get the equality of the annihilator ideals

$$\mathrm{ann}(p_i) \;=\; \mathrm{ann}(q_i)$$

(iii) **Invariant Factors:** If $M \neq 0$ is non-zero and finitely generated, then there are some $f, r \in \mathbb{N}$ and a set $\{ d_i \mid i \in 1 \ldots r \} \subseteq R$ of scalars, such that the following three properties are satisfied

(1) for any $i \in 1 \ldots r$ we have $d_i \in R^\bullet$

(2) for any $i \in 2 \ldots r$ we have $d_{i-1} \mid d_i$

(3) M is isomorphic, as an R-module, to the direct sum:

$$M \;\cong_{\mathfrak{m}}\; \bigoplus_{i=1}^{r} R \Big/ d_i R \oplus R^f$$

A set of scalars $\{ d_i \mid i \in 1 \dots r \} \subseteq R$ that satisfies the properties (1) to (3) above is called *invariant factors* of M. And thereby we get the additional properties

$$\begin{aligned} f &= \mathsf{free}(M) \\ f + r &= \mathsf{rank}(M) \\ r = 0 &\iff M \text{ is free} \\ f = 0 &\iff M \text{ is a torsion-module} \end{aligned}$$

(iv) If $M \neq 0$ is non-zero and finitely generated, then the invariant factors of M are *essentially* unique, in the following sense: If $g \in \mathbb{N}$ and $\{ e_j \mid j \in 1 \dots s \} \subseteq R$ is another set of invariant factors of M

$$\begin{aligned} M &\cong_{\mathsf{m}} \bigoplus_{i=1}^{r} R \Big/ d_i R \oplus R^f \\ M &\cong_{\mathsf{m}} \bigoplus_{j=1}^{s} R \Big/ e_j R \oplus R^g \end{aligned}$$

then we already have $f = g$ and $r = s$ and for any $i \in 1 \dots r$ there is some unit $u_i \in R^*$ such that

$$e_i = u_i d_i$$

(v) **Elementary Divisors:** If $M \neq 0$ is non-zero and finitely generated, then there are some $f, s \in \mathbb{N}$, a set $\{ p(j) \mid j \in 1 \dots s \} \subseteq R$ of prime elements of R and powers $n(i,j) \in \mathbb{N}$ (where $i \in 1 \dots I(j)$), such that for any $j, k \in 1 \dots s$ the following three properties are satisfied

(1) $p(j) \approx p(k) \implies j = k$

(2) $n(1,j) \geq n(2,j) \geq \cdots \geq n(I(j),j) \geq 1$

(3) M is isomorphic, as an R-module, to the following direct sum:

$$M \cong_{\mathsf{m}} \bigoplus_{j=1}^{s} \bigoplus_{i=1}^{I(j)} R \Big/ p(j)^{n(i,j)} R \oplus R^f$$

A set of prime elements $\{ p(j) \mid j \in 1 \dots s \} \subseteq R$ and powers $\{ (n(i,j) \mid j \in 1 \dots s, i \in 1 \dots I(j) \}$ that satisfies the properties (1) to (3) above are called *elementary divisors* of M.

(vi) If $M \neq 0$ is non-zero and finitely generated, then the elementary divisors of M are *essentially* unique, in the following sense: If $g \in \mathbb{N}$ and $\{ e_j \mid j \in 1 \dots s \} \subseteq R$ is another set of elementary divisors of M

$$\begin{aligned} M &\cong_{\mathsf{m}} \bigoplus_{j=1}^{s} \bigoplus_{i=1}^{I(j)} R \Big/ p(j)^{n(i,j)} R \oplus R^f \\ M &\cong_{\mathsf{m}} \bigoplus_{\ell=1}^{t} \bigoplus_{k=1}^{K(\ell)} R \Big/ q(\ell)^{m(k,\ell)} R \oplus R^g \end{aligned}$$

then we already have $f = g$ and $s = t$ and there is a permutation $\sigma : 1 \dots s \longleftrightarrow 1 \dots t$ such that

for any $j \in 1 \ldots s$ and any $i \in 1 \ldots I(j)$

(1) $p(j) \approx q(\sigma(j))$

(2) $I(j) = K(\sigma(j))$

(3) $n(i,j) = m(i,\sigma(j))$

(5.33) Remark:

- Theorem (iii) is an ultimate consequence of proposition (5.28): As M is finitely generated there is some epimorphism $\psi : R^n \twoheadrightarrow M$ where $n = \mathrm{rank}(M)$. Let $P := \mathrm{kn}(\psi)$ be kernel of that epimorphism, which is a sub-module of R^n. Then we can apply (5.28.(iv)) to P such that there is a basis $\{ p_1, \ldots, p_r, m_1, \ldots, m_f \}$ of R^n and $\{ d_1, \ldots, d_r \} \subseteq R$ such that $\{ d_i p_i \mid i \in 1 \ldots r \}$ is a basis of P. Then R^n/P can be written as a direct sum of R/d_iR. As $n = \mathrm{rank}(M)$ there are no $d_i \in R^*$. And any m_j that occurs in the basis of R^n but not among the $\{ p_1, \ldots, p_r \}$ adds an R to this direct sum. Then the first isomorphism theorem $R^n/P \xrightarrow{\sim} M$ can be twisted, as to give the desired isomorphy.

- If the base ring R even is an Euclidean domain (and not only a PID) we can omit the preparations of (5.28), as we can replace theorem (iv) by (4.88.(iii)). Here's how: If $n := \mathrm{rank}(M)$ and we pick up some generators $M = \mathrm{Lh}\{ x_1 \ldots, x_n \}$ then we have an epimorphism

$$\varrho \; : \; R^n \twoheadrightarrow M \; : \; (b_i) \mapsto \sum_{i=1}^{n} b_i x_i$$

Thereby $\mathrm{kn}(\varrho) \leq_{\mathsf{m}} R^n$ is a free module, as R^n is free and R is a PID. That is there is a basis $\{ a_1, \ldots, a_r \} \subseteq R^n$ of $\mathrm{kn}(\varrho)$. If we denote the matrix $A := (a_1\, a_2 \ldots a_r) \in \mathrm{mat}_{n,r}(R)$ with the columns $\mathrm{col}_i(A) = a_i$, then $\mathrm{kn}(\varrho) = \mathrm{Lh}\{ a_1, \ldots, a_r \} = \mathrm{im}(A)$. But we can use (4.88.(iii)) to turn A into the form

$$\begin{pmatrix} d_1 & & 0 \\ & \ddots & \\ 0 & & d_r \\ 0 & \ldots & 0 \\ \vdots & & \vdots \\ 0 & \ldots & 0 \end{pmatrix} = D = SAT = S \begin{pmatrix} | & & | \\ a_1 & \cdots & a_r \\ | & & | \end{pmatrix} T$$

where $S \in \mathrm{gl}_n(R)$, $T \in \mathrm{gl}_r(R)$ and $d_{i-1} \mid d_i$ for any $i \in 2 \ldots r$. Thereby the d_i are the invariant factors of M, so we have found an alternative way of computing these (for Euclidean domains). Let us argue, why: As $D = SAT$ we have $A = S^{-1}DT^{-1}$ and thereby $\mathrm{im}(A) = S^{-1}\mathrm{im}(D)$ by (4.45.(iii)). But $\mathrm{im}(D) = d_1R \oplus \cdots \oplus d_rR \oplus 0^f$ (where $f := n - r$) and thereby we have

$$\bigoplus_{i=1}^{r} R \Big/ d_iR \oplus R^f \; = \; R^n \Big/ \mathrm{im}(D) \; \xrightarrow{\sim} \; R^n \Big/ \mathrm{kn}(\varrho)$$

where the isomorphism is given by $b + \mathrm{im}(D) \mapsto S^{-1}b + \mathrm{kn}(\varrho)$. Thus we have found a decomposition of M with the d_i as invariant factors:

$$\bigoplus_{i=1}^{r} R \Big/ d_i R \oplus R^f \quad \xrightarrow{\sim} \quad M \ : \ b + \mathrm{im}(D) \mapsto \varrho\big(S^{-1}b\big)$$

(5.34) Remark:
Let $(R, +, \cdot)$ be a PID and M be a non-zero, finitely generated R-module. Then we find the following correspondences between these forms of M:

- *Invariant Factors to Invariant Ideals:* Consider M in the invariant factor form of (5.32.(iii)), let $n := r + f = \mathrm{rank}(M)$ and $d_j := 0$ for any $j > r$. Then $R/d_jR = R$ and $d_{i-1} \mid d_i$ is true for any $i \in 2 \ldots n$, such that the isomorphism takes the form

 $$\Phi \ : \ \bigoplus_{i=1}^{n} R \Big/ d_i R \quad \xrightarrow{\sim} \quad M$$

 For any $j \in 1 \ldots n$ let $g_j := (\delta_{i,j} + d_i R)$ be the canonical generators of the module on the left side. Then the $m_j := \Phi(g_j) \in M$ generate $M = Rm_1 \oplus \cdots \oplus Rm_n$ of M and $\mathrm{ann}(m_j) = \mathrm{ann}(g_j) = d_i R$ such that we have the chain $\mathrm{ann}(m_1) \ \supseteq \ \ldots \ \supseteq \ \mathrm{ann}(m_n)$ of invariant ideals.

- *Invariant Ideals to Invariant Factors:* If $M = Rm_1 \oplus \cdots \oplus Rm_n$ such that $\mathrm{ann}(m_1) \ \supseteq \ \ldots \ \supseteq \ \mathrm{ann}(m_n)$ then we let $d_i R = \mathrm{ann}(m_i)$ and $r := \max\{\, i \in 1 \ldots n \mid \mathrm{ann}(m_i) \neq 0 \,\}$. If we now regard the epimorphism

 $$\varrho \ : \ R^n \ \twoheadrightarrow \ M \ : \ (a_i) \mapsto \sum_{i=1}^{n} a_i m_i$$

 then $\mathrm{kn}(\varrho) = d_1 R \oplus \cdots \oplus \ldots d_r R \oplus 0^f$ where $f = n - r$. Thereby the d_i are the invariant factors of M and we find the isomorphism

 $$\Phi \ : \ \bigoplus_{i=1}^{r} R \Big/ d_i R \oplus R^f \quad \xrightarrow{\sim} \quad M \ : \ (a_i) + \mathrm{kn}(\varrho) \mapsto \sum_{i=1}^{n} a_i m_i$$

- *Invariant Factors to Elementary Divisors:* If M is in invariant factor form again (as above) and we look at the isomorphy

 $$\Phi \ : \ \bigoplus_{i=1}^{r} R \Big/ d_i R \oplus R^f \quad \xrightarrow{\sim} \quad M$$

 Then we use a decomposition of d_r into prime factors $d_r = \alpha_r p(1)^{n(1)} \ldots p(s)^{n(s)}$ where the $p(j) \in R$ are pairwise non-associated primes and $n(j) \geq 1$. Then, as $d_i \mid d_r$ all the d_i have the a prime decomposition of the form

 $$d_i \quad = \quad \alpha_i \prod_{j=1}^{s} p(j)^{\langle p(j) | d_i \rangle}$$

for any $i \in 1 \dots r$. Let $n(i,j) := \langle p(j) \mid d_{r+1-i} \rangle \in \mathbb{N}$ where $j \in 1 \dots s$ and $i \in 1 \dots r$ and let $I(j) := \#\{ i \in 1 \dots r \mid n(i,j) \neq 0 \}$. Then we found the elementary divisors of M, as

$$\bigoplus_{j=1}^{s} \bigoplus_{i=1}^{I(j)} R \Big/ p(j)^{n(i,j)} R \oplus R^f \quad \xrightarrow{\sim} \quad M$$

In a less formalistic, but easier to understand way, let us build up a table containing the powers of $p(j)$ occuring in the prime factorisation of d_i. Then then powers $n(i,j)$ of the elementary divisors occur in this table, in inverse order

	$p(1)$	$p(2)$	$\cdots$	$p(s)$
d_1	$n(r,1)$	$n(r,2)$	$\cdots$	$n(r,s)$
$\vdots$	$\vdots$	$\vdots$		$\vdots$
d_{r-1}	$n(2,1)$	$n(2,2)$	$\cdots$	$n(2,s)$
d_r	$n(1,1)$	$n(1,2)$	$\cdots$	$n(1,s)$

- *Elementary Divisors to Invariant Factors:* If conversely we have the elementary divisors of M, as in (5.32.(v)): $r := \max\{ I(j) \mid j \in 1 \dots s \}$ and $n(i,j) := 0$ for any $j \in 1 \dots s$ and $I(j) < i \leq r$. Then

$$d_i \quad := \quad \prod_{j=1}^{s} p(j)^{n(r+1-i,j)} \quad \in \quad R$$

are the invariant factors of M (that is: you can use the table above, to multiply up the d_i along the rows of this table) such that we find an isomorphism of the form

$$\bigoplus_{i=1}^{r} R \Big/ d_i R \oplus R^f \quad \xrightarrow{\sim} \quad M$$

5.3 Diagonalization

To begin with let us think of a little geometry: A linear map may dilate (and contract) vectors and even rotate around a certain axis. What a linear map cannot is shift, as $\varphi(0) = 0$ is fixed. E.g. consider

$$A := \begin{pmatrix} 0.5 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 2 \end{pmatrix}, \quad B := \begin{pmatrix} \cos(\alpha) & -\sin(\alpha) & 0 \\ \sin(\alpha) & \cos(\alpha) & 0 \\ 0 & 0 & 1 \end{pmatrix} \in \mathrm{mat}_3(\mathbb{R})$$

Clearly A shrinks any vector $x \in \mathbb{R}^3$ by half in the direction of e_1 (= the x-Axis) and doubles x in the direction of e_3 (= the z-Axis). The direction of e_2 (= the y-Axis) is unaffected. Thus if A is in diagonal form it is plain to see, which direction is dilated by which factor.

B is another interesting example: It rotates any vector $x \in \mathbb{R}^3$ around the e_3-Axis (= z-Axis) by the angle α [if we look down from the positive side of the z-Axis the rotation is counter-clockwise]. Thereby the e_3-coordinate of x remains unchanged. That is any cylinder with $\mathbb{R}e_3$ as its middle axis is invariant under the action of B. Here we see the property the rotation axis must have: It is invariant under the action of φ. That is we look out for vectors $x \in R^n$ such that

$$\varphi(x) \quad = \quad \lambda x$$

for some $\lambda \in R$. These vectors will be called *eigenvectors* of φ [*eigen* is a German word meaning *own* or *self*, so it could be translates as a vector belonging to φ]. The factor λ is the dilation factor of x and will be called *eigenvalue* of φ. It might be appealing to study eigenvectors simply for geometrical reasons, but the theory provides much more: First of all eigenvectors are the fundamental notion of canonical form theory - most notably the Jordan normal form. The Jordan normal form is the key when trying to solve a system of ordinary, linear differential equations (linear ODEs). For example chaos theory relies heavily on this.

In statistics consider the problem: Given data $(x_1, x_2, \ldots, x_n)$ for every single individual within a large group and of course these values x_j vary. There may be certain unknown variables u_i behind the scene, that control entire combinations of the x_j - e.g. a tall person usually has large feet and is heavier. But the colour of eyes is independent of height. An intelligent student will probably have better grades all around, a student who has to work for his living has less time for his studies and may have worse grades. Factor analysis now tries to find the combinations of variables x_j that belong to a common controlling variable u_i. These combinations will be the eigenvectors of the variance matrix of the x_j and the corresponding eigenvalues will be the weights to what extend the variance of this combination contributes to the variance of the entire set of data. In quantum mechanics a linear map φ models an observable such as location, energy or impulse. A vector x models the state the physical system is in - which is a probability distribution over the certain "pure" states. These pure states are the eigenvectors of φ, the eigenvalue λ is the result of measuring φ if the system is in that state.

We could go on with applications of this beautiful theory for quite some time, but by now it should be clear, that it is truly fundamental and closely linked to applications. For now we stick to the case of finitely many dimensions however, which covers most of its applications - but not quantum mechanics. General quantum mechanics requires the theory of unbound operators and also is genuinely stochastic which both is beyond the scope of this textbook.

(5.35) Definition:
Let $(R,+,\cdot)$ be an arbitrary ring, M be an R-module and consider $\varphi \in \mathrm{end}(M)$, that is a linear map $\varphi : M \to M$ from M to itself. Then a sub-module $P \leq_{\mathsf{m}} M$ is said to be **invariant** under φ iff

$$\varphi(P) \quad \subseteq \quad P$$

And a vector $x \in M$ is said to be an **eigenvector** of φ to the **eigenvalue** $\lambda \in R$, if we have the equation

$$\varphi(x) \quad = \quad \lambda\, x$$

The set of all eigenvectors to a given $\lambda \in R$ is called the **eigenspace** of φ to λ. And the set of all eigenvalues of φ is said to be the **spectrum** of φ. We will denote these sets by

$$\begin{array}{rcl} \mathrm{Eig}_\varphi(\lambda) & := & \mathrm{kn}\,(\varphi - \lambda \mathbb{1}_M) \\ & = & \{\, x \in M \mid \varphi(x) = \lambda x \,\} \\ \mathrm{Spec}(\varphi) & := & \Big\{\, \lambda \in R \mid \mathrm{Eig}_\varphi(\lambda) \neq 0 \Big\} \\ & = & \{\, \lambda \in R \mid \exists\, x \in M : x \neq 0 \text{ and } \varphi(x) = \lambda x \,\} \end{array}$$

(5.36) Example: (viz. 960)
Let $(R,+,\cdot)$ is an integral domain, M an R-module and $\varphi \in \mathrm{end}(M)$ be an R-module endomorphism. Suppose there is a basis $\{\, m_1, \ldots, m_n \,\}$ of M, such that for any $j \in 1 \ldots n$ there is some $a_j \in R$ such that $\varphi(m_j) = a_j m_j$ (such an endomorphism will later be called *diagonizable*). Then for any $\lambda \in R$

$$\mathrm{Eig}_\varphi(\lambda) \quad = \quad \mathrm{Lh}\{\, m_j \mid j \in 1 \ldots n,\, a_j = \lambda \,\}$$

In particular all the eigenspaces of a diagonizable endomorphism φ are finitely generated and free R-sub-modules of M again. Their dimension is given to be the number of a_j that equal λ

$$\mathrm{rank}\big(\mathrm{Eig}_\varphi(\lambda)\big) \quad = \quad \#\,\{\, j \in 1 \ldots n \mid a_j = \lambda \,\}$$

(5.37) Proposition: (viz. 960)
Let $(R,+,\cdot)$ be a commutative ring, M be an R-module and $\varphi \in \mathrm{end}(M)$ be a module-endomorphism on M. Then the following statements hold true:

(i) Let $I \neq \emptyset$ be any index set and for any $i \in I$ let $P_i \leq_{\mathsf{m}} M$ be a φ-invariant sub-module of M, then the sum and the intersection of the P_i are φ-invariant sub-modules of M, too

$$\begin{array}{rcl} \varphi\left(\sum\limits_{i\in I} P_i\right) & \subseteq & \sum\limits_{i\in I} P_i \\ \varphi\left(\bigcap\limits_{i\in I} P_i\right) & \subseteq & \bigcap\limits_{i\in I} P_i \end{array}$$

(ii) For any $\lambda \in R$ the eigenspace of φ to λ a sumbodule of M, that is invariant under φ, which means

$$\varphi\left(\mathrm{Eig}_\varphi(\lambda)\right) \quad \subseteq \quad \mathrm{Eig}_\varphi(\lambda)$$

And if M is torsion free [which is $ax = 0 \implies a = 0$ or $x = 0$], then any eigenspace $\mathrm{Eig}_\varphi(\lambda)$ even is a pure sub-module of M, that is for any $a \in R$ with $a \neq 0$ we get the implication

$$ax \in \mathrm{Eig}_\varphi(\lambda) \quad \implies \quad x \in \mathrm{Eig}_\varphi(\lambda)$$

Nota if R is a PID, then by (4.109.(ii)) this implies, that any eigenspace of φ is complemented, that is $M = \mathrm{Eig}_\varphi(\lambda) \oplus Q$ for some $Q \leq_{\mathsf{m}} M$. However, Q need not be φ-invariant again.

(iii) Let R be an integral domain and M be free and finitely generated. Then the spectrum of φ is precisely the set of roots of the polynomial function $R \to R : \lambda \mapsto \det(\varphi - \lambda \mathbb{1}_M)$, that is

$$\mathrm{Spec}(\varphi) \quad = \quad \{\, \lambda \in R \mid \det(\varphi - \lambda \mathbb{1}_M) = 0 \,\}$$

(iv) Let R be an integral domain and M be torsion-free, then eigenvectors to distinct eigenvalues are linearly independent: Given $\lambda_1, \ldots, \lambda_n \in R$ pairwise distinct elements [that is $\lambda_i = \lambda_j \implies i = j$] of R and $x_i \in \mathrm{Eig}_\varphi(\lambda_i)$ with $x_i \neq 0$ for any $i \in 1 \ldots n$ then $\{\, x_1, \ldots, x_n \,\}$ is linearly independent.

(v) More generally: If R is an integral domain, M is torsion-free and $\lambda_1, \ldots, \lambda_n \in R$ are pairwise distinct elements of R, again. Then we consider some subsets $U_i \subseteq \mathrm{Eig}_\varphi(\lambda_i)$ where $i \in 1 \ldots n$. If now all the U_i are linearly independent, then U is linearly independent as well:

$$U \quad := \quad \bigcup_{i=1}^{n} U_i \quad \subseteq \quad M$$

(5.38) Example:
Let $(R, +, \cdot)$ be an integral domain, fix $1 \leq n \in \mathbb{N}$ and consider the diagonal matrix D with entries $\lambda_1, \ldots, \lambda_n \in R$ and another matrix J which has $\lambda \in R$ on the diagonal and $1 \in R$ one step above

$$D \quad := \quad \begin{pmatrix} \lambda_1 & 0 & \cdots & 0 \\ 0 & \lambda_2 & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \cdots & 0 & \lambda_n \end{pmatrix}, \quad J \quad := \quad \begin{pmatrix} \lambda & 1 & & 0 \\ & \lambda & \ddots & \\ & \ddots & \ddots & 1 \\ 0 & & & \lambda \end{pmatrix}$$

Then the spectrum of D is precisely $\mathrm{Spec}(D) = \{\, \lambda_1, \ldots, \lambda_n \,\}$, whereas J only has λ in its spectrum $\mathrm{Spec}(J) = \{\, \lambda \,\}$. And if $\{\, e_1, \ldots, e_n \,\}$ is the usual Euclidean basis of R^n then for any $\alpha \in R$ the eigenspace of α is given to be

$$\begin{aligned} \mathrm{Eig}_D(\alpha) \quad &= \quad \mathrm{Lh}\{\, e_i \mid i \in 1 \ldots n,\, \lambda_i = \alpha \,\} \\ \mathrm{Eig}_J(\lambda) \quad &= \quad R\, e_1 \end{aligned}$$

These are the two classic examples: D shows how neatly the eigenspaces of a diagonal matrix are arranged and J is an example of a matrix that cannot be diagonalized. These matrices J will later be called *Jordan-blocks*.

Prob Clearly $De_i = \lambda_i e_i$ such that any $e_i \in \mathrm{Eig}_D(\lambda_i)$ is an eigenvectors of D to the eigenvalue λ_i, in particular $\lambda_i \in \mathrm{Spec}(D)$. Conversely the equation $Dx = \alpha x$ breaks down into n equations in R, namely $\lambda_i x_i = \alpha x_i$ and hence $(\lambda_i - \alpha)x_i = 0$. So if $\alpha \notin \{\lambda_1, \ldots, \lambda_n\}$ then (as R is an integral domain) $x_i = 0$ for any $i \in 1 \ldots n$ and hence $x = 0$. Thus the λ_i are all the eigenvalues D has. The same reasoning shows that $Dx = \alpha x$ implies $x \in \mathrm{Lh}\{ e_i \mid i \in 1 \ldots n, \lambda_i = \alpha \}$ and the converse inclusion is clear.
Prob Clearly $Je_1 = \lambda e_1$ such that e_1 is an eigenvector of J to the eigenvalue λ. Conversely the equation $Jx = \alpha x$ breaks down into the equations $\lambda x_n = \alpha x_n$ and $\lambda x_i + x_{i+1} = \alpha x_i$ for any $1 \leq i < n$. Thus if $\alpha \neq \lambda$ then (since R is an integral domain) we have $x_n = 0$. Then the $(n-1)$-th equation is $\lambda x_{n-1} = \alpha x_{n-1}$ such that $x_{n-1} = 0$ as well. By induction we find that $x = 0$, such that λ is the one and only eigenvalue of J. The matrix $\lambda \mathbb{1}_n - J = -N$ has the entries -1 on the upper off-diagonal only. Hence $(\lambda \mathbb{1}_n - J)x = -(x_2, x_3, \ldots, x_n, 0)$. From this we see, that the kernel of $\lambda \mathbb{1}_n - J$ is precisely $R\, e_1$ and this is the eigenspace of J to the eigenvalue λ.

(5.39) Example:
Consider any commutative ring R, e.g. $R = \mathbb{Z}$ and the free R-module $M := R^3$ of dimension 3. The endomorphism $\varphi(a,b,c) := (2a, c, 0)$ has the following representation as a matrix (in the euclidean basis)

$$A \;=\; \begin{pmatrix} 2 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}$$

Obviously $e_1 = (1,0,0)$ is an eigenvector of A, to the eigenvalue 2, as $Ae_1 = 2e_1$ and also e_2 is an eigenvector of A, to the eigenvalue 0, as $Ae_2 = 0e_2$ - generally $\mathrm{Eig}_\varphi(0) = \mathrm{kn}(\varphi)$. It is clear [e.g. be regarding the characteristic polynomial $c_\varphi(t) = t^2(t-2)$, see below] that 0 and 2 are the only eigenvalues of φ. Both eigenspaces are direct summands of M, as

$$R^3 \;=\; Re_1 \oplus Re_2 \oplus Re_3 \;=\; \mathrm{Eig}_\varphi(2) \oplus \mathrm{Eig}_\varphi(0) \oplus Re_3$$

However the complement Re_3 is *not* invariant under φ, as $Ae_3 = e_2 \in \mathrm{Eig}_\varphi(0)$. This example shows, that is well possible, that a vector outside an eigenspace can be sucked into an eigenspace (under φ). But once inside they remain trapped, regardless of how many times we apply φ.

(5.40) Remark:
If $(R, +, \cdot)$ is a commutative ring, $f \in R[t]$ is a polynomial and A an element of an R-algebra, in our case here $A \in \mathrm{mat}_n(R)$ a square matrix over R, then we defined the *evaluation* of f in A to be the following element of the R-algebra again:

$$f(A) \;=\; \sum_{k=0}^{\infty} f[k] A^k \;\in\; \mathrm{mat}_n(R)$$

This is well-defined, as f has finite degree d, such that in truth the sum is finite only. More explicitly, if $f(t) = a_d t^d + \cdots + a_1 t + a_0$ then $f(A)$ is given to be

$$f(A) \;=\; a_d A^d + \cdots + a_1 A + a_0 \mathbb{1}_n$$

And if M is an R-module, then $\mathrm{end}(M)$ also is an R-algebra, under the composition of maps, for multiplication. Hence we may evaluate $f \in R[t]$ is an R-module endomorphism $\varphi \in \mathrm{end}(M)$, as well

$$f(\varphi) \;=\; \sum_{k=0}^{\infty} f[k]\varphi^k \;\in\; \mathrm{end}(M)$$

By construction of $R[t]$ the evaluation $R[t] \to \mathrm{end}(M) : f \mapsto f(\varphi)$ is a homomorphism of R-algebras. For convenience, if $f(t) = a_d t^d + \cdots + a_1 t + a_0$ again, then

$$f(\varphi) \;=\; a_d \varphi^d + \cdots + a_1 \varphi + a_0 \mathbb{1}_M$$

Recall that $\mathrm{mat}_n(R) \xrightarrow{\sim} \mathrm{end}(R^n) : A \mapsto \varphi_A$ is an isomorphism of R-algebras, where $\varphi_A(x) = Ax$. The inverse of this isomorphism is the basis representation $\mathrm{end}(R^n) \to \mathrm{mat}_n(R) : \varphi \mapsto [\varphi]_{\mathcal{E}}$, where $\mathcal{E}$ is the Euclidean basis of R^n. It is clear, that for any $x \in M$ and $k \in \mathbb{N}$ we have $\varphi_A^k(x) = A^k x$ and thereby $f(\varphi_A)(x) = f(A)x$. Generally, as $A \mapsto \varphi_A$ is an R-algebra homomorphism, it is clear that

$$f(\varphi_A) \;=\; \varphi_{f(A)}$$

(5.41) Definition:
Let $(R, +, \cdot)$ be a commutative ring and M be a free, finitely generated R-module. If now $\varphi \in \mathrm{end}(M)$ is an endomorphism of modules, then we introduce the following notions:

(i) For a square matrix $A = (a_{i,j}) \in \mathrm{mat}_n(R)$ over R we regard the following square matrix (of the same size) over the polynomial ring $R[t]$

$$t\mathbb{1}_n - A \;=\; \begin{pmatrix} t - a_{1,1} & -a_{1,2} & \cdots & -a_{1,n} \\ -a_{2,1} & t - a_{2,2} & \ddots & \vdots \\ \vdots & \ddots & \ddots & -a_{n-1,n} \\ -a_{n,1} & \cdots & -a_{n,n-1} & t - a_{n,n} \end{pmatrix}$$

This is an $(n \times n)$-matrix over the polynomial ring $R[t]$ and thereby we define the **characteristic polynomial** $c_A(t)$ of A to be the determinant of this matrix

$$c_A(t) \;:=\; \det\big(t\mathbb{1}_n - A\big) \;\in\; R[t]$$

(ii) For an endomorphism $\varphi \in \mathrm{end}(M)$ we define the **characteristic polynomial** $c_\varphi(t)$ of φ using the following construction: Choose any ordered basis $\mathcal{M} \subseteq M$ of M and let $A := [\varphi]_{\mathcal{M}}$ be the matrix representation of φ, then $c_\varphi(t)$ is taken to be

$$c_\varphi(t) \;:=\; c_A(t) \;\in\; R[t]$$

Prob We need to check that this is well-defined, that is if $\mathcal{M}$ and $\mathcal{M}'$ are any two ordered bases and $A = [\varphi]_{\mathcal{M}}$ and $A' = [\varphi]_{\mathcal{M}'}$ are the respective matrix representations, then we need to show $c_A(t) = c_{A'}(t)$. Yet by (4.42.(iii)) there is an invertible matrix $T \in \mathrm{mat}_n(R)$ such that $A' = TAT^{-1}$. And since $t\mathbb{1}_n$ commutes with any matrix of $\mathrm{mat}_n(R[t])$ we find $T(t\mathbb{1}_n - A)T^{-1} = Tt\mathbb{1}_nT^{-1} - TAT^{-1} = t\mathbb{1}_n - A'$. And as T is invertible in $\mathrm{mat}_n(R[t])$ as well (with the same inverse) (4.55.(ii)) implies that the determinants are equal

$$\begin{aligned} c_{A'}(t) &= \det(t\mathbb{1}_n - A') = \det(T(t\mathbb{1}_n - A)T^{-1}) \\ &= \det(T) \cdot \det(t\mathbb{1}_n - A) \cdot \det(T)^{-1} \\ &= \det(t\mathbb{1}_n - A) = c_A(t) \end{aligned}$$

(iii) Let $\lambda \in R$ be any scalar, then we define the **algebraic multiplicity** of λ in $\varphi \in \mathrm{end}(M)$ to be the largest natural number $m \in \mathbb{N}$ such that $(t-\lambda)^m$ divides the charakteristic polynomial of φ

$$\mathrm{AM}_\varphi(\lambda) := \max\Big\{ k \in \mathbb{N} \mid (t-\lambda)^k \mid c_\varphi(t) \Big\}$$

(iv) For any scalar $\lambda \in R$ we also define the **geometric multiplicity** of λ in $\varphi \in \mathrm{end}(M)$ to be the rank of the eigenspace $\mathrm{Eig}_\varphi(\lambda) = \{ x \in M \mid \varphi(x) = \lambda x \}$ of φ to the eigenvalue λ

$$\mathrm{GM}_\varphi(\lambda) := \mathrm{rank}\Big(\mathrm{Eig}_\varphi(\lambda)\Big)$$

(v) Let R be an integral domain and M an arbitrary R-module: The **minimal polynomial** of $\varphi \in \mathrm{end}(M)$ is the uniquely determined polynomial that satisfies the following three properties - refer to (5.40) for details on $f(\varphi)$ and note, that generally φ might not have a minimal polynomial, at all

(1) $m_\varphi(\varphi) = 0$

(2) m_φ is monic

(3) $\forall f \in R[t] : f(\varphi) = 0 \implies m_\varphi \mid f$

Prob Suppose $m_1(t)$ and $m_2(t)$ satisfy the above three properties. In particular, as $m_2(\varphi) = 0$ we have $m_1 \mid m_2$. Likewise $m_1 \mid m_2$ and as R is an integral domain this yields $m_1 = am_2$ for some $a \in R[t]^* = R^*$. But as both are monic we can compare coefficients to find $m_1 = m_2$.

(5.42) Proposition: (viz. 976)
If $(R, +, \cdot)$ is an integral domain, M is an R-module and $\varphi \in \mathrm{end}(M)$ is an endomorphism of M, then we get the following statements concerning the minimal polynomial of φ

(i) The set $\{ f \in R[t] \mid f(\varphi) = 0 \}$ is an ideal of $R[t]$, called the *null ideal* of φ. In fact it is the kernel of the evaluation homomorphism $R[t] \to \mathrm{end}(M) : f \mapsto f(\varphi)$, that is

$$\{ f \in R[t] \mid f(\varphi) = 0 \} = \mathrm{kn}\big(f \mapsto f(\varphi)\big) \trianglelefteq_{\mathrm{i}} R[t]$$

(ii) If M is free and finitely generated and the null ideal of φ is a principal ideal then there also is a monic polynomial $m_\varphi \in R[t]$ that generates it, and in this case m_φ is the minimal polynomial of φ

$$m_\varphi R[t] \;=\; \{\, f \in R[t] \mid f(\varphi) = 0 \,\}$$

(iii) There are several equivalent formulations of whether a polynomial $m \in R[t]$ is the minimal polynomial $m = m_\varphi$ of φ: That is the following three statements are equivalent

(a) The polynomial m satisfies: (1) m is monic, (2) $m(\varphi) = 0$ and (3) for any $f \in R[t]$ we find that $f(\varphi) = 0$ implies $m \mid f$.

(b) The polynomial m satisfies: (1) m is monic, (2) $m(\varphi) = 0$ and (3) for any $f \in R[t]$ with $f \neq 0$ we find that $f(\varphi) = 0$ implies $\deg(m) \leq \deg(f)$.

(c) The polynomial m satisfies: (1) m is monic and (2) m generates the null ideal of φ, formally that is: $mR[t] = \{\, f \in R[t] \mid f(\varphi) = 0 \,\}$.

(iv) The null ideal $\mathfrak{v}_\varphi := \{\, f \in R[t] \mid f(\varphi) = 0 \,\}$ is a prime ideal of the polynomial ring $R[t]$ and if m is the minimal polynomial of φ, then m is a prime element of the polynomial ring $R[t]$.

(v) If $P \leq_{\mathsf{m}} M$ is a φ-invariant sub-module, that is $\varphi(P) \subseteq P$ again, and $\varphi \mid P : P \to P$ denotes the restriction of φ to P, then - supposed the minimal polynomials of φ and $\varphi \mid P$ exist - we find the following divisibility relation

$$m_{\varphi|P} \;\mid\; m_\varphi$$

(5.43) Example: (viz. 962)

(i) If $A = a\mathbb{1}_n$, that is A is the matrix belonging to $\varphi(x) = ax$ for some $a \in R$, then the minimal polynomial of A is $m_A(t) = t - a$, as clearly $m_A(A) = 0$ already. And for the characteristic polynomial of A we find $c_A(t) = (t-a)^n$, as the multi-linearity of the determinant yields

$$\det(t\mathbb{1}_n - a\mathbb{1}_n) \;=\; \det\big((t-a)\mathbb{1}_n\big) \;=\; (t-a)^n \det(\mathbb{1}_n) \;=\; (t-a)^n$$

(ii) More generally: If $A = \mathrm{dia}(a_1, \ldots, a_n)$ is a diagonal matrix, let λ_i be the distinct elements among the a_j. That is $\{\, \lambda_1, \ldots, \lambda_r \,\} = \{\, a_1, \ldots, a_n \,\}$ and $\lambda_i = \lambda_j$ is true for $i = j$ only. Also let $k(i)$ be the number of occurrences of λ_i among the a_j, that is $k(i) := \#\big\{\, j \in 1 \ldots n \mid a_j = \lambda_i \,\big\}$. If R is a commutative ring, then we find c_A and if R even is a noetherian integral domain we also find m_A

$$\begin{aligned} c_A(t) &= \prod_{i=1}^{r} (t - \lambda_i)^{k(i)} \\ m_A(t) &= \prod_{i=1}^{r} (t - \lambda_i) \end{aligned}$$

(iii) If $T = (t_{i,j}) \in \mathrm{tri}_n(R)$ is an upper (or lower) triangular matrix, then the characteristic polynomial of T splits into the linear factors $t - t_{ii}$, where $t_{i,i}$ is an element on the diagonal of T

$$c_T(t) \;=\; \prod_{i=1}^{n} (t - t_{i,i})$$

(iv) An easy example is the general 2×2 matrix A, that has the rows (a, b) and $(c, d) \in R^2$. For this matrix the characteristic polynomial is

$$\det \begin{pmatrix} t-a & -b \\ -c & t-d \end{pmatrix} \;=\; (t-a)(t-d) - bc \;=\; t^2 - (a+d)t + ad - bc$$

(v) If $A \in \mathrm{mat}_n(R)$ is any square matrix and A^* is the transpose of A, then both A and A^* share the same characteristic polynomial, since

$$\begin{aligned} c_{A^*}(t) &= \det(t\mathbb{1}_n - A^*) \;=\; \det((t\mathbb{1}_n - A)^*) \\ &= \det(t\mathbb{1}_n - A) \;=\; c_A(t) \end{aligned}$$

(vi) For a monic polynomial $f \in R[t]$ of degree $n := \det(f)$ let us introduce the **companion matrix** of f to be the following $n \times n$ square matrix

$$\mathrm{comp}(f) \;:=\; \begin{pmatrix} 0 & 0 & \cdots & 0 & -f[0] \\ 1 & 0 & \cdots & 0 & -f[1] \\ 0 & 1 & \cdots & 0 & -f[2] \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 1 & -f[n-1] \end{pmatrix} \;\in\; \mathrm{mat}_n(R)$$

For example let us present the companion matrix of the polynomial $f(t) = t^2 + at + b$ and compute its characteristic polynomial

$$\begin{aligned} \mathrm{comp}(f) &= \begin{pmatrix} 0 & -b \\ 1 & -a \end{pmatrix} \\ \det \begin{pmatrix} t & b \\ -1 & t+a \end{pmatrix} &= t(t+a) + b \;=\; t^2 + at + b \end{aligned}$$

Note that the Euclidean basis $\{ e_1, e_2, \ldots, e_n \}$ is cycled in the following way: $\mathrm{comp}(f)e_k = e_{k+1}$ for any $1 \leq k < n$ and $\mathrm{comp}(f)e_n = -(f[0], f[1], \ldots, f[n-1])$. But more importantly both, the characteristic polynomial and the minimal polynomial of $\mathrm{comp}(f)$ are f again:

$$c_{\mathrm{comp}(f)}(t) \;=\; m_{\mathrm{comp}(f)}(t) \;=\; f(t)$$

(5.44) Lemma: (viz. 963) **Cayley-Hamilton Theorem**

(i) Let $(R, +, \cdot)$ be commutative ring and $A \in \mathrm{mat}_n(R)$ be an $n \times n$ matrix over R. Then the characteristic polynomial $c_A(t) = \det(t\mathbb{1}_n - A) \in R[t]$ is a monic polynomial of degree n over R, whose coefficients are given to be

$$c_A(t) \;=\; t^n - \mathrm{tr}(A)t^{n-1} + \cdots + (-1)^n \det(A) \;\in\; R[t]$$

More generally the k-th coefficient $c_A[k]$ of $c_A(t)$ where $k \in 0 \ldots n-1$ is given to be $(-1)^k$ times the sum of all *prinicipal minors* of A of size $r = n - k$. That is we have the formula:

$$c_A(t) \;=\; t^n + \sum_{r=1}^{n} (-1)^r \left(\sum_{\alpha \in \mathrm{Asc}(r,n)} \det\big(A[\alpha \mid \alpha]\big) \right) t^{n-r}$$

(ii) If we regard $A \in \mathrm{mat}_n(R)$ as an endomorphism $A : R^n \to R^n$ by virtue of $A(x) = Ax$, then A satisfies its own characteristic polynomial, that is we have

$$c_A(A) \;=\; \sum_{k=0}^{n} c_A[k] A^k \;=\; 0 \;\in\; \mathrm{mat}_n(R)$$

(iii) If $(R, +, \cdot)$ is a commutative ring, M a free, finitely generated R-module and $\varphi \in \mathrm{end}(M)$ an R-module endomorphism of M, then φ satisfies its own characteristic polynomial

$$c_\varphi(\varphi) \;=\; \sum_{k=0}^{n} c_\varphi[k] \varphi^k \;=\; 0 \;\in\; \mathrm{end}(M)$$

(iv) If $(R, +, \cdot)$ is a commutative ring again, M is any finitely generated R-module and $\varphi : M \to M$ is an R-module endomorphism, then there is a polynomial $f(t) \in R[t]$ of $\deg(f) = \mathrm{rank}(M)$ such that φ satisfies f, formally that is

$$f(\varphi) \;=\; \sum_{k=0}^{\mathrm{rank}(M)} f[k] \varphi^k \;=\; 0 \;\in\; \mathrm{end}(M)$$

(v) If $(R, +, \cdot)$ is a commutative ring, $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is an ideal of R, M is any finitely generated R-module and $\varphi : M \to M$ is an R-module endomorphism such that $\varphi(M) \subseteq \mathfrak{a}M$, then φ is integral over $\mathfrak{a}$. That is there are $n \geq 1$ and $a_0, \ldots, a_{n-1} \in \mathfrak{a}$ such that

$$\varphi^n + a_{n-1}\varphi + \cdots + a_1 \varphi + a_0 \mathbb{1} \;=\; 0 \;\in\; \mathrm{end}(M)$$

(5.45) Remark:

(i) The proof of the general formula in (5.44.(i)) is a technical ordeal. It is far easier to only prove the reduced formula $c_A(t) = t^n - \mathrm{tr}(A) + \cdots \pm \det(A)$ only, which can be done by induction on n. And actually the only property truly needed is the fact that $c_A(t)$ is a polynomial of degree n with $c_A(0) = \det(A)$. So the reader is actually better off to prove this by induction, as an exercise, than to work through the proof here.

(ii) The proof of (5.44.(ii)) also is more or less technical and relies heavily on Cramer's rule. But why do we need to prove this anyway? Isn't it obvious that $c_A(A) = \det(A\mathbb{1}_n - A) = \det(0) = 0$? Well yes, of course $\det(A\mathbb{1}_n - A) = \det(0) = 0 \in R$. What Cayley-Hamilton tell us, is that if we evaluate the polynomial c_A in A we obtain the zero-matrix $c_A(A) = 0 \in \mathrm{mat}_n(R)$ and this is quite a different story, as there are many matrices with zero-determinant, that are non-zero themselves!

(iii) From now on we have to be aware, that we have two different ways of evaluating a polynomial $f \in R[t]$: First of all we can compute $f(a) \in R$ for any $a \in R$, as we did before. But secondly we can now compute $f(\varphi) \in \mathrm{end}(M)$ for any $\varphi \in \mathrm{end}(M)$. A special case is $A \in \mathrm{mat}_n(R)$ where $M = R^n$. Not to distinguish between these two different notions may lead to misconceptions like the one we described in (ii). In particular $c_A(B)$ is *not* $\det(B\mathbb{1}_n - A)$ [unless $n = 1$], as the first is an element of $\mathrm{mat}_n(R)$ and the latter is an element of R.

(iv) Part (iv) of the Cayley-Hamilton theorem is proved indenpendently from part (iii). Of course, if M also is free, then we are done, by pointing out $f = c_\varphi$. But in (iv) we did not require M to be free. So we loose the information which polynomial f turns φ to 0, but still, there is one.

(v) If $c_A(0) = \det(A) \in R^*$ is invertible, then A is invertible. Using the Cayley-Hamilton theorem we always have the following equation

$$\begin{aligned} 0 &= c_A(A) = A^n + \sum_{r=1}^{n-1} c_A[r] A^r + \det(A)\mathbb{1}_n \\ &= A\left(A^{n-1} + \sum_{r=1}^{n-1} c_A[r] A^{r-1}\right) + \det(A)\mathbb{1}_n \end{aligned}$$

Thus if $\det(A)$ is invertible, this equation may be used to show, that the inverse even is a polynomial (of degree $n-1$) in A, namely we can compute A^{-1} by virtue of

$$A^{-1} = \frac{1}{\det(A)}\left(A^{n-1} + \sum_{r=0}^{n-2} c_A[r+1] A^r\right)$$

(5.46) Proposition: (viz. 977)

(i) Let $(R, +, \cdot)$ be a commutative ring, M an R-module and $\varphi \in \mathrm{end}(M)$ an R-module endomorphism. If now $x \in M$ such that $\varphi(x) = \lambda x$ for some $x \in R$, then for any polynomial $f \in R[t]$ we get

$$f(\varphi)(x) = f(\lambda)\, x$$

(ii) If $(E, +, \cdot)$ is a field and V is a finitely generated E-vector space, then any E-vector space endomorphism $\varphi \in \mathrm{end}(V)$ has a (uniquely determined) minimal polynomial m_φ.

(iii) If $(R, +, \cdot)$ is a normal domain (e.g. an UFD), M a finitely generated, free R-module and $\varphi \in \mathrm{end}(M)$ an endomorphism of R-modules, then φ has a (uniquely determined) minimal polynomial m_φ.

(iv) Let $(R, +, \cdot)$ be an integral domain, M a free, finitely generated R-module and $\varphi \in \mathrm{end}(M)$ be an R-module endomorphism. Then the characteristic polynomial c_φ and minimal polynomial m_φ (if it exists) share the same roots in R. That is for any $\lambda \in R$ we get the equivalences

(a) $\lambda \in \mathrm{Spec}(\varphi)$

(b) $c_\varphi(\lambda) = 0$

(c) $m_\varphi(\lambda) = 0$

(d) $\det(\varphi - \lambda \mathbb{1}_M) = 0$

(v) Let $(R, +, \cdot)$ be a PID, M a free, finitely generated R-module and $\varphi \in \mathrm{end}(M)$ be an R-module endomorphism. Then for any $\lambda \in \mathrm{Spec}(\varphi)$ the dimension of the eigenspace of φ to λ lies in between 1 and the algebraic multiplicity of λ

$$1 \leq \mathrm{GM}_\varphi(\lambda) \leq \mathrm{AM}_\varphi(\lambda)$$

(5.47) Remark: (■)
In fact (5.46.(iii)) can be extended a little: If R is a normal domain (that is an integral domain, that is integrally closed in its quotient field), then any square matrix over R has a minimal polynomial and vice versa. That is for an integral domain R the following three statements are equivalent:

(a) R is a normal domain

(b) For any $A \in \mathrm{mat}_n(R)$ the ideal $\{ f \in R[t] \mid f(A) = 0 \}$ of $R[t]$ is principal

(c) For any $A \in \mathrm{mat}_n(R)$ the ideal $\{ f \in R[t] \mid f(A) = 0 \}$ of $R[t]$ is generated by a monic polynomial

That (a) implies (c) is (iii) and has also been shown by W. C. Brown in his paper Null Ideals and spanning Ranks of Matrices (1998), whereas (b) implies (a) has been proved by S. Frisch in Integrally closed Domains, Minimal Polynomials and Null Ideals of Matrices (2004) and (c) implies (b) is trivial.

(5.48) Proposition: (viz. 984)
Let $(R, +, \cdot)$ be commutative ring and L, M and N be finitely generated, free R-modules. Then we get the following statements

(i) If $\varphi \in \mathrm{end}(M)$ is an endomorphism on M and $\Phi : M \xrightarrow{\sim} N$ is an isomorphism of R-modules then the characteristic polynomial of the transferred endomorphism $\psi := \Phi\varphi\Phi^{-1} \in \mathrm{end}(N)$ is unchanged

$$c_\psi(t) = c_\varphi(t)$$

If now $f \in R[t]$ is any polynomial, then $f(\psi) = \Phi f(\varphi)\Phi^{-1}$ and hence ψ has a minimal polynomial if and only if φ has a minimal polynomial. And in this case we also get:

$$m_\psi(t) = m_\varphi(t)$$

(ii) If $\varphi \in \mathrm{end}(M)$ and $P \leq_\mathrm{m} M$ is a free sub-module of M such that $\varphi(P) \subseteq P$ and M/P is free, too, then we denote the maps

$$\begin{array}{rcll} \varphi \mid P & : & P \to P & : x \mapsto \varphi(x) \\ \overline{\varphi} & : & M\big/_P \to M\big/_P & : x + P \mapsto \varphi(x) + P \end{array}$$

Thereby the characteristic polynomial of φ splits into the characteristic polynomials of $\varphi \mid P$ and $\overline{\varphi}$ and in particular the characteristic polynomial of the restriction $\varphi \mid P$ divides $c_\varphi(t)$

$$c_\varphi(t) = c_{\varphi|P}(t) \cdot c_{\overline{\varphi}}(t)$$

(iii) If $\varphi \in \mathrm{end}(M)$ again and M is the inner direct sum $M = P_1 \oplus \cdots \oplus P_r$ where for any $i \in 1 \ldots r$ the sub-module $P_i \leq_{\mathfrak{m}} M$ is free, finitely generated and $\varphi(P_i) \subseteq P_i$ then we denote the restrictions $\varphi_i := \varphi \mid P_i$ again. And thereby the characteristic polynomial of φ splits into

$$c_\varphi(t) \;=\; \prod_{i=1}^{r} c_{\varphi_i}(t)$$

(iv) *Theorem of Fitting*: If M is a free R-module of $\dim(M) = n$ and $\varphi \in \mathrm{end}(M)$ an endomorphism of M and $f_1, \ldots, f_n \in R[t]$ are any polynomials such that $f_i(\varphi) = 0$ for any $i \in 1 \ldots n$, then the characteristic polynomial of φ divides the product of the f_i, formally

$$c_\varphi \;\mid\; f_1 \cdot \ldots \cdot f_n$$

(v) Let $\lambda \in \mathrm{end}(L)$, $\mu \in \mathrm{end}(M)$ and $\nu \in \mathrm{end}(N)$. Further let $\varphi : L \to M$ and $\psi : M \to N$ be homomorphisms of R-modules. Suppose that the following diagram is commutative and that its rows are exact, then we get: $c_\mu(t) \;=\; c_\lambda(t) \cdot c_\nu(t)$

$$\begin{array}{ccccccccc}
0 \to & L & \xrightarrow{\varphi} & M & \xrightarrow{\psi} & N & \to & 0 \\
 & \downarrow \lambda & \circlearrowleft & \downarrow \mu & \circlearrowleft & \downarrow \nu & & \\
0 \to & L & \underset{\varphi}{\longrightarrow} & M & \underset{\psi}{\longrightarrow} & N & \to & 0
\end{array}$$

(vi) If $(S, +, \cdot)$ is another commutative ring and $\alpha : R \to S$ is a homomorphism of rings, then we turn S into an R-algebra using $as := \alpha(a)s$ for $a \in R$ and $s \in S$. If now $\varphi \in \mathrm{end}(M)$ then we regard the change of base rings $M_S := S \otimes M$ and $\varphi_S := S \otimes \varphi \in \mathrm{end}(M_S)$. If now

$$\widetilde{\alpha} \;:\; R[t] \;\to S[t] \;:\; \sum_{k=0}^{\infty} a_k t^k \;\mapsto\; \sum_{k=0}^{\infty} \alpha(a_k) t^k$$

Then the characteristic polynomial of the endomorphism φ_S changed to S is just the characteristic polynomial of φ mapped under $\widetilde{\alpha}$

$$c_{\varphi_S}(t) \;=\; \widetilde{\alpha}\left(c_\varphi(t)\right)$$

(5.49) Corollary: (viz. 992)
Let $(R, +, \cdot)$ is an integral domain and M is a free, finitely generated R-module of dimension $n := \dim(M)$. Consider an R-module endomorphism $\varphi \in \mathrm{end}(M)$ that has a minimal polynomial (e.g. if R is an UFD). Then the minimal polynomial divides the characteristic polynomial, which in turn divides the n-th power of the minimal polynomial

$$m_\varphi \;\mid\; c_\varphi \quad \text{and} \quad c_\varphi \;\mid\; m_\varphi^n$$

In particular the minimal polynomial m_φ and characteristic polynomial c_φ share the same prime factors: That is for any prime element $p \in R[t]$ we have $p \mid m_\varphi \iff p \mid c_\varphi$.

(5.50) Definition:
Let $(R,+,\cdot)$ be a commutative ring $1 \leq n \in \mathbb{N}$ and $A \in \mathrm{mat}_n(R)$ be a square matrix over R. Then A is said to be a **diagonal matrix**, iff for any $i \neq j \in 1 \ldots n$ we have $a_{i,j} = 0$. In other words there are some $\lambda_1, \ldots, \lambda_n \in R$ [namely $\lambda_i = a_{i,i}$] such that A is given to be

$$A \quad = \quad \begin{pmatrix} \lambda_1 & 0 & \cdots & 0 \\ 0 & \lambda_2 & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \cdots & 0 & \lambda_n \end{pmatrix}$$

And A is said to be **diagonizable** iff there an invertible matrix $T \in \mathrm{gl}_n(R)$ such that TAT^{-1} is a diagonal matrix. Let now M be a free, finitely generated R-module, then an endomorphism $\varphi \in \mathrm{end}(M)$ is said to be **diagonizable** iff there is some ordered basis $\mathcal{M} \subseteq M$ of M such that the matrix representation $[\varphi]_{\mathcal{M}}$ of φ is a diagonal matrix.

$$\exists\, \mathcal{M} \subseteq M \text{ ordered basis of } M, \text{ such that } [\varphi]_{\mathcal{M}} \text{ is a diagonal matrix}$$

An entire set $\{ \varphi_i \mid i \in I \} \subseteq \mathrm{end}(M)$ of endomorphisms of M is said to be **simultaneously diagonizable** iff there is some ordered basis $\mathcal{M}$ of M, such that all matrix representations $[\varphi_i]_{\mathcal{M}}$ are diagonal matrices

$$\exists\, \mathcal{M} \subseteq M \text{ ordered basis of } M, \text{ such that } \forall\, i \in I \,:\, [\varphi_i]_{\mathcal{M}} \text{ is a diagonal matrix}$$

(5.51) Remark:
If $(R,+,\cdot)$ is an integral domain, M is a free, finitely generated R-module and $\varphi \in \mathrm{end}(M)$ a diagonizable endomorphism of M, the we will see next, that there is an R-basis $\{ m_1, \ldots, m_n \}$ of M, such that for any $j \in 1 \ldots n$ there is some $a_j \in R$, such that $\varphi(m_j) = a_j m_j$. Clearly, the matrix representation of φ in the ordered basis $\mathcal{M} := (m_1, \ldots, m_n)$ is diagonal

$$[\varphi]_{\mathcal{M}} \quad = \quad \begin{pmatrix} a_1 & 0 & \cdots & 0 \\ 0 & a_2 & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \cdots & 0 & a_n \end{pmatrix}$$

We have studied this situation before: In example (5.36) we have seen that for any $\lambda \in R$ the eigenspace of φ to λ is the following free, finitely generated sub-module of M

$$\mathrm{Eig}_{\varphi}(\lambda) \quad = \quad \mathrm{Lh}\{ m_j \mid j \in 1 \ldots n,\, a_j = \lambda \}$$

And in example (5.43.(ii)) we continued: Let λ_i be the distinct elements among the a_j again. That is $\{ \lambda_1, \ldots, \lambda_r \} = \{ a_1, \ldots, a_n \}$ and $\lambda_i = \lambda_j$ is true for $i = j$ only. Then by in (5.38) we know that

$$\mathrm{Spec}(\varphi) \quad = \quad \{ \lambda_1, \ldots, \lambda_r \}$$

And if $k(i)$ is the number of occurrences of λ_i among the a_j, that is $k(i) := \#\{ j \in 1 \ldots n \mid a_j = \lambda_i \}$, then

(for a general commutative ring R) we found the characteristic polynomial of φ to be

$$c_\varphi(t) \;=\; \prod_{i=1}^{r}(t-\lambda_i)^{k(i)}$$

And if R even is a noetherian integral domain, then in (5.43.(ii)) we have also been able to prove, that the minimal polynomial of φ is the much same, only without multiplicities

$$m_\varphi(t) \;=\; \prod_{i=1}^{r}(t-\lambda_i)$$

(5.52) Theorem: (viz. 988)
Let $(R,+,\cdot)$ be a commutative ring, M be a free, finitely generated R-module. Also let $\varphi \in \mathrm{end}(M)$ be an R-module endomorphism and $\mathrm{Spec}(\varphi) = \{\lambda_1,\ldots,\lambda_r\} \subseteq R$ be the spectrum of φ. Then the following statements are equivalent - recall that in this case φ is said to be *diagonizable*:

(a) There is a basis $\{m_1,\ldots,m_n\} \subseteq M$ (for some $n \in \mathbb{N}$) of M, such that for any $i \in 1\ldots n$ there is some $\lambda_i \in R$, such that $\varphi(m_i) = \lambda_i m_i$.

(b) There is an ordered basis $\mathcal{M} \subseteq M$ of M, such that the matrix representation $[\varphi]_{\mathcal{M}}$ of φ in $\mathcal{M}$ is a diagonal matrix, formally: $\exists\,\lambda_1,\ldots,\lambda_n \in R : [\varphi]_{\mathcal{M}} = \mathrm{dia}(\lambda_1,\ldots,\lambda_n)$.

(c) For any ordered basis $\mathcal{M} \subseteq M$ of M the matrix representation $[\varphi]_{\mathcal{M}}$ of φ in $\mathcal{M}$ is a diagonizable matrix, formally: $\exists\,\lambda_1,\ldots,\lambda_n \in R : [\varphi]_{\mathcal{M}} \approx \mathrm{dia}(\lambda_1,\ldots,\lambda_n)$.

If R even is an integral domain, then we may append this list of equivalences: In this case (d) and (e) are equivalent to the above statements (a) to (c), as well, where:

(d) For any $i \in 1\ldots r$ the eigenspace $\mathrm{Eig}_\varphi(\lambda_i)$ is a free sub-module of M and M is the sum of the eigenspaces of φ

$$M \;=\; \sum_{i=1}^{r}\mathrm{Eig}_\varphi(\lambda_i)$$

(e) For any $i \in 1\ldots r$ the eigenspace $\mathrm{Eig}_\varphi(\lambda_i)$ is a free sub-module of M and M is an inner direct sum of the eigenspaces of φ

$$M \;=\; \bigoplus_{i=1}^{r}\mathrm{Eig}_\varphi(\lambda_i)$$

By (5.51), if R is an integral domain, then (a) implies property (h) and (h) implies (f). Also, if R is a noetherian, normal domain, then (a) also implies (g). If R even is a field, the converse implications are true, as well: In case R is a field (f) to (h) are equivalent to the above statements (a) to (e), where:

(f) The sum of the dimensions of all the eigenspaces of φ equals the dimension of M, that is we have

$$\dim(M) \;=\; \sum_{i=1}^{r}\mathrm{GM}_\varphi(\lambda_i)$$

(g) The minimal polynomial of φ splits into distinct linear factors over R. These linear factors are then

given to be $t - \lambda_i$, where the λ_i are the distinct eigenvalues of φ. Altogether we get

$$m_\varphi \;=\; \prod_{i=1}^{r}(t-\lambda_i)$$

(h) The characteristic polynomial of φ splits over R and for any eigenvalue λ_i of φ the algebraic multiplicities $\mathrm{AM}_\varphi(\lambda_i) = k(i)$ and geometric multiplicities $\mathrm{GM}_\varphi(\lambda_i) = \dim(\mathrm{Eig}_\varphi(\lambda_i))$ coincide

$$c_\varphi(t) \;=\; \prod_{i=1}^{r}(t-\lambda_i)^{k(i)} \quad \text{where} \quad k(i) \;=\; \dim\bigl(\mathrm{Eig}_\varphi(\lambda_i)\bigr)$$

criteria to be diagonizable AW 4.4.30 bis 4.4.32 und 4.4.40 und 4.4.49 how to diagonalize a matrix + example simultaneous diagonalization AW 4.3.36 spectral projections

5.4 Normal Forms

The theory of diagonalization is powerful and beautiful. Yet not every matrix is diagonalizable, not even over $\mathbb{C}$. Hence we need to look at other useful representations of an endomorphism as a matrix. In general (over a field) we find the *rational canonical form*. This is a block diagonal form, in which every block is the companion matrix of a polynomial. In case the characteristic polynomial splits the rational canonical form turns into the *Jordan normal form*.
The rational canonical form is closely related to the invariant factor theorem. In fact, if E is a field, then $E[t]$ is a PID, such that a finitely generated module M over $E[t]$ can be decomposed into invariant factors. We will find both the minimal polynomial and the characteristic polynomial in terms of these factors. But in order to do so, we first have to turn M into a module over the polynomial ring:

(5.53) Definition: (viz. 973)
Let $(R,+,\cdot)$ be a commutative ring, $(M,+,\diamond)$ be an R-module and fix an R-module-endomorphism $\varphi \in \mathrm{end}(M)$. Then we turn M into a module $(M_\varphi,+,\curlywedge)$ over the polynomial ring $R[t]$ using the following construction: The base set of M_φ is just M again: $M_\varphi := M$. Also the addition $+$ on M_φ is just the addition $+$ of M. The new ingredient is another scalar multiplication $\curlywedge$ on M_φ defined by

$$\curlywedge \;:\; R[t] \times M_\varphi \to M_\varphi \;:\; (f,x) \mapsto f(\varphi)(x) \;=\; \sum_{k=0}^{\infty} f[k]\varphi^k(x)$$

Again we write $fx := f \curlywedge x = f(\varphi)(x)$. More explicitly: If $f \in R[t]$ is any polynomial over R, written as $f = a_n t^n + \cdots + a_1 t + a_0 \in R[t]$ and $x \in M_\varphi$ is any element of M_φ, then the scalar multiplication is

$$fx \;=\; f(\varphi)(x) \;=\; a_n\varphi^n(x) + \cdots + a_1\varphi(x) + a_0 x$$

Nota even though $M_\varphi = M$ is the same set and the addition $+$ is identical we have to distinguish M and M_φ because of the different base ring and scalar multiplication. And as we only write M_φ in place of $(M_\varphi,+,\curlywedge)$ we have no other option, as to adapt the name of the base set.

(5.54) Remark:
The above definition might look a little artificial, but in fact it is a most ingenious construction that links module theory to linear algebra. In fact the entire theory of canonical forms of an endomorphism (e.g. Jordan canonical form) will arise by applying the invariant factor theorem to this module. Hence it is worthwhile to linger here for a moment to reflect on what we just defined:

As we have seen in (3.71.(vii)) $(\mathrm{end}(M),+,\circ)$ is a (non-commutative) ring under the point-wise addition $\varphi+\psi : x \mapsto \varphi(x)+\psi(x)$ and the composition $\circ$ of maps as multiplication $\varphi\psi : x \mapsto \varphi(\psi(x))$. Thereby $R \subseteq \mathrm{end}(M)$ can be considered a sub-ring, using the embedding $a \hookrightarrow a\mathbb{1}_M$. If now $f = a_n t^n + \cdots + a_1 t + a_0 \in R[t]$ is any polynomial over R, then we can evaluate f in φ

$$f(\varphi) \;=\; a_n\varphi^n + \cdots + a_1\varphi + a_0\mathbb{1}_M \;\in\; \mathrm{end}(M)$$

Thereby $f(\varphi)$ is a well-defined endomorphism of M again. And the scalar multiplication on M_φ has then been defined by the action of $f(\varphi)$ on M, that is we have

$$fx \;=\; f(\varphi)(x) \;=\; a_n\varphi^n(x) + \cdots + a_1\varphi(x) + a_0x$$

Note that the image of the ring-homomorphism $R[t] \to \mathrm{end}(M) : f \mapsto f(\varphi)$ is the commutative sub-ring $R[\varphi]$ of $\mathrm{end}(M)$. And also we see that $fx = 0$ if and only if $f(\varphi)(x) = 0$ and thereby the annihilator of $x \in M_\varphi$ is the set of all polynomials f such that $f(\varphi)(x) = 0$, formally

$$\mathrm{ann}(x) \;=\; \{\, f \in R[t] \mid f(\varphi)(x) = 0 \,\}$$

And thereby the annihilator of the entire module M_φ is the set of all polynomials f such that $f(\varphi) = 0$ is the zero map $M \to M : x \mapsto 0$, formally again

$$\mathrm{ann}(M_\varphi) \;=\; \{\, f \in R[t] \mid f(\varphi) = 0 \,\}$$

(5.55) Proposition: (viz. 974)
Let $(R, +, \cdot)$ be a commutative ring and consider two R-modules M and N. Also let $\mu \in \mathrm{end}(M)$ and $\nu \in \mathrm{end}(N)$ be two endomorphisms on these. Then the following statements are true:

(i) The $R[t]$-sub-modules of M_μ are precisely the μ-invariant R-sub-modules of M. That is for any subset $P \subseteq M$ we find the equivalence

$$P \;\leq_{\mathsf{m}}\; M_\mu \quad\Longleftrightarrow\quad P \;\leq_{\mathsf{m}}\; M \text{ and } \mu(P) \;\subseteq\; P$$

(ii) The $R[t]$-linear maps from M_μ to N_ν are precisely the R-linear maps φ from M to N that commute with μ and ν. More formally we find, that

$$\mathrm{mhom}_{R[t]}(M_\mu, N_\nu) \;=\; \{\, \varphi \in \mathrm{mhom}_R(M,N) \mid \varphi\mu \;=\; \nu\varphi \,\}$$

(iii) Let $\varepsilon \in \mathrm{end}(M)$ be another endomorphism on M and $\Phi : M \to M$ be a map from M to itself. Then Φ is an isomorphism from M_ε to M_φ if and only if Φ is an automorphism of M that commutes with ε and φ. That is the following equivalence golds true

$$\Phi : M_\mu \xrightarrow{\sim} M_\varepsilon \quad\Longleftrightarrow\quad \Phi : M \xrightarrow{\sim} M \text{ with } \varepsilon = \Phi\mu\Phi^{-1}$$

(5.56) Proposition: (viz. 974)
Let $(R, +, \cdot)$ be a commutative ring, M be an arbitrary R-module and fix an R-module endomorphism $\varphi \in \mathrm{end}(M)$. Then we obtain the following statements:

(i) For any $x \in M$ the subset $R[t]x \subseteq M_\varphi$ is a φ-invariant sub-module of M (and of M_φ) for which we get the inclusion $Rx \subseteq R[t]x \leq_{\mathsf{m}} M_\varphi$. Explicitly $R[t]x$ is given to be

$$R[t]\,x \;=\; \mathrm{Lh}_R\{\, \varphi^k(x) \mid k \in \mathbb{N} \,\}$$

(ii) If $x \in M_\varphi$ and $f \in R[t]$ is a monic polynomial of degree $n := \deg(f)$ with $fx = 0$, then $R[t]x$ even is finitely generated, as an R-module, since

$$R[t]x \;=\; \mathrm{Lh}_R\{\, \varphi^k(x) \mid 0 \le k < n \,\}$$

(iii) If $P \;\le_{\mathrm{m}}\; M$ is an φ-invariant sub-module of M and $x \in P$, then $R[t]x \subseteq P$. And if P is generated as $P = \mathrm{Lh}\{\, p_i \mid i \in I \,\}$ then P is also generated by

$$P \;=\; \sum_{i\in I} R[t]\, p_i$$

(iv) If M is a finitely generated R-module, then M_φ is a finitely generated $R[t]$-torsion module and the rank of M_φ does not exceed the rank of M, formally

$$\mathrm{rank}_{R[t]}(M_\varphi) \;\le\; \mathrm{rank}_R(M)$$

(5.57) Proposition: (viz. 979)
Let $(R, +, \cdot)$ be a commutative ring and M be free R-module of finite dimension $n = \dim(M) < \infty$. If now $\varphi \in \mathrm{end}(M)$ is an endomorphism of M, then the following statements are true:

(i) For any $x \in M$ the following four statements are equivalent - and in this case x is said to be a **cyclic** vector for φ

(a) $M_\varphi \;=\; R[t]\, x$

(b) $M \;=\; \mathrm{Lh}_R\{\, \varphi^k(x) \mid k \in \mathbb{N} \,\}$

(c) $M \;=\; \mathrm{Lh}_R\{\, \varphi^k(x) \mid 0 \le k < n \,\}$

(d) $\{\, \varphi^k(x) \mid 0 \le k < n \,\}$ is a basis of M

(ii) If $x \in M$ is a cyclic vector of M_φ and we denote the ordered basis $\mathcal{M} = (x, \varphi(x), \ldots, \varphi^{n-1}(x))$ then there is a monic polynomial $f \in R[t]$ of degree n such that $fx = 0$ and

$$[\varphi]_{\mathcal{M}} \;=\; \mathrm{comp}(f)$$

(iii) If $\mathcal{M} = (x_1, x_2, \ldots, x_n)$ is an ordered basis of M such that $[\varphi]_{\mathcal{M}} = \mathrm{comp}(f)$ for some monic polynomial $f \in R[t]$ then we find the following isomorphy of $R[t]$-modules

$$R[t] \,\big/\, fR[t] \;\xrightarrow{\sim}\; M_\varphi \;:\; g + fR[t] \;\mapsto\; gx_1$$

(iv) Combining the three items above, we find the equivalence of the following properties (a) to (c). Thereby the polynomials f in (b) and (c) have to be the same.

(a) There is some $x \in M$ such that $x \in M_\varphi$ is a cyclic vector.

(b) There is an ordered basis $\mathcal{M}$ of M and a monic polynomial $f \in R[t]$ such that $[\varphi]_{\mathcal{M}} = \mathrm{comp}(f)$.

(c) There is an some monic polynomial $f \in R[t]$ of degree $\deg(f) = n$ such that we have an isomorphy of the following $R[t]$-modules

$$R[t] \Big/ {}_{fR[t]} \;\cong_{\mathfrak{m}}\; M_\varphi$$

(5.58) Corollary: (viz. 981)
Rational canonical Form: Let $(E, +, \cdot)$ be a field and V be a finite-dimensional E-vector-space. Also fix an endomorphism $\varphi \in \mathrm{end}(V)$ of V. Then we pick up the invariant ideals of the $E[t]$-module V_φ: That is there some elements $x_1, \ldots, x_r \in V$ such that

(1) $V \;=\; E[t]x_1 \oplus \cdots \oplus E[t]x_r$ and

(2) $\mathrm{ann}(x_1) \;\supseteq\; \ldots \;\supseteq\; \mathrm{ann}(x_r)$

For any $i \in 1 \ldots r$ pick up the monic generator $f_i \in E[t]$ of the annihilator ideal $\mathrm{ann}(x_i) = f_i E[t]$ and say $n(i) := \deg(f_i)$. Then $n(i) = \dim(E[t]x_i) \geq 1$, as well and we get the following statements:

(i) $f_1 \mid f_2$ and $f_2 \mid f_3$ and so on until $f_{r-1} \mid f_r$

(ii) $f_r = m_\varphi$ is the minimal polynomial of φ

(iii) $f_1 \cdot \ldots \cdot f_r = c_\varphi$ is the characteristic polynomial of φ

(iv) For any $i \in 1 \ldots r$ the E-subspace $E[t]x_i$ has the ordered basis $\mathcal{V}_i := (x_i, \varphi(x_i), \ldots, \varphi^{n(i)-1}(x_i))$. And if we take $\mathcal{V} := (\mathcal{V}_1, \ldots, \mathcal{V}_r)$ this is an ordered basis of V and the matrix representation of φ in this basis is the block-diagonal matrix of the companion matrices of the f_i, that is

$$[\varphi]_{\mathcal{V}} \;=\; \mathrm{comp}(f_1) \oplus \cdots \oplus \mathrm{comp}(f_r)$$

(5.59) Remark:
We continue with a field E, a finite-dimensional E-vector space V and a fixed endomorphism $\varphi \in \mathrm{end}(V)$. Suppose the characteristic polynomial c_φ splits, that is, there are some $\lambda_1, \ldots, \lambda_s \in E$ and powers $1 \leq n(1), \ldots, n(s) \in \mathbb{N}$ such that c_φ can be written, as

$$c_\varphi(t) \;=\; \prod_{j=1}^{s} (t - \lambda_j)^{n(j)}$$

As in (5.58) let $f_1, \ldots, f_r \in E[t]$ be the invariant factors of V_φ. By the above corollary we have $f_r = m_\varphi$ and $c_\varphi = f_1 \ldots f_r$ and generally the ascending chain of divisibilities $f_1 \mid f_2 \mid \ldots \mid f_r = m_\varphi \mid c_\varphi$. If c_φ splits, then the same is true for all its divisors. That is

$$f_i(t) \;=\; \prod_{j=1}^{s} (t - \lambda_j)^{k(i,j)}$$

for some $0 \leq k(i,j) \leq n(j)$. In particular m_φ has the algebraic multiplicities $1 \leq k(j) = k(r,j)$. The divisibilities dictate $k(1,j) \leq \cdots \leq k(r,j)$ and as the invariant factors f_1 to f_{r-1} have to fill the gap

between m_φ and c_φ we find the following equations for any $j \in 1 \ldots s$:

$$n(j) - k(j) \;=\; \sum_{i=1}^{r-1} k(i,j)$$

So what are these invariant factors f_i for $1 \leq i < r$?

(5.60) Proposition: (viz. 982)
Let $(R, +, \cdot)$ be any commutative ring and M be an R-module. Then we use *change of base rings* (3.158) and regard the R-module and $R[t]$-module $M_{R[t]} := R[t] \otimes M$.

(i) By (3.146.(v)) any element of $M_{R[t]}$ can be written in the following form, where $d \in \mathbb{N}$ and $x_k \in M$. And this representation is *unique* in the sense that the x_k thereby are uniquely determined

$$\sum_{k=0}^{d} t^k \otimes x_k$$

(ii) If M is a free R-module having the R-basis $\{ m_1, \ldots, m_n \}$ then by (3.160.(i)) $M_{R[t]}$ is a free $R[t]$-module, having the $R[t]$-basis $\{ \mathbf{1} \otimes m_1, \ldots, \mathbf{1} \otimes m_n \}$.

Now fix any endomorphism $\varphi \in \mathrm{end}(M)$ of R-modules. Then we introduce two well-defined homomorphisms $\Delta_\varphi : M_{R[t]} \to M_{R[t]}$ and $\pi_\varphi : M_{R[t]} \to M_\varphi$ of $R[t]$-modules by linear expansion of

$$\begin{aligned} \Delta_\varphi\big(f \otimes x\big) \;&:=\; (tf) \otimes x + f \otimes \varphi(x) \\ \pi_\varphi\big(f \otimes x\big) \;&:=\; fx \;=\; f(\varphi)(x) \end{aligned}$$

(iii) These maps now form an exact chain of homomorphisms of $R[t]$-modules (or R-modules, whatever you prefer). That is the following chain of π_φ after Δ_φ is exact

$$0 \;\to\; M_{R[t]} \;\to\; M_{R[t]} \;\to\; M_\varphi \;\to\; 0$$

(iv) Thereby, if $\{ m_i \mid i \in I \} \subseteq M$ generates M as an R-module, then $\{ t \otimes m_i - \mathbf{1} \otimes \varphi(m_i) \mid i \in I \}$ generates the kernel $\mathrm{kn}(\pi_\varphi) \leq_{\mathfrak{m}} M_{R[t]}$ as an $R[t]$-module.

(v) If M is a free, finitely generated R-module, then so is $M_{R[t]}$ by (ii). And in this case we find the characteristic polynomial of φ to be the determinant of Δ_φ

$$\det\big(\Delta_\varphi\big) \;=\; c_\varphi(t) \;\in\; R[t]$$

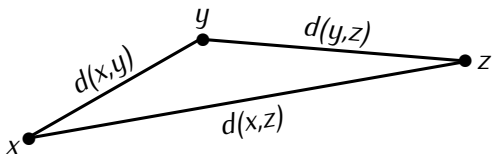
5.6 Solving linear ODEs

Chapter 6



Functional Analysis

There are two ways of generalizing linear algebra of finite-dimensional vector-spaces: For one you can replace the base field by a (commutative) ring. This is what we did before in module theory. It turned out, that modules have a very rich structure and we have been able to classify finitely generated modules over PIDs.
The second generalisation you can think of is regarding non-finite vector-spaces. From a purely algebraic view, this is nothing new - the vector space still is of the form $E^{\oplus I}$ for some index set I with $|(|I)$ equal to its dimension. But that's not the end of the story: As always dropping a finiteness condition we need to replace it by some topology, in order to proceed. And we want to continue towards the spectral theory of bounded operators.
While unbounded operators are far more interesting in applications (quantum mechanics) they give rise to a theory that is based on measure, probability and integration theory. This has to be dealt with in a textbook similar to this one here. So what we do here is restrict ourselves to the base field of the real and complex numbers and venture on into the borderlands between linear algebra and analysis.

6.1 Metrics and Topologies

Both of these notions - metrics and topologies - are used to describe a notion of nearby or farther away, respectively. While metrics formalize the notion of distance in a very obvious way, topologies are a more abstract but very general concept. Truth is, both of these notions are native to analysis, as they are the prerequisites needed to define convergence. But it turned out, that topology is a very useful tool in algebra, too and there are instances, where you cannot proceed without.
We have tried to present an introduction into general topology in a very convincing way: We first introduce metrics and their properties and derive all the notions we use from topology from this case. In doing so, we try to enlighten the ideas, that lie at the bottom of the constructions in general topology.
So we want to measure distances: Say x and y are points in some space X. What properties do we expect from a function $d(x,y)$, that measures the distance between these points? Well, if $x = y$, then clearly $d(x,y) = 0$, otherwise not. Actually it is open to discussion, whether $d(x,y) = 0$ should imply $x = y$. We might want to drop this requirement, if our way of measuring a distance is less accurate, than the proximity of x and z. This happens in integration theory, where two functions can differ on a set of measure zero. But we will see, that this makes little difference.

The second property the distance $d(x,y)$ should satisfy is $d(x,y) = d(y,x)$. If this would not be satisfied, then the space in question would be non-isotropic: It would make a difference to go from x to y or the other way around. The last property is taken from plane geometry: Let fix x and z and place another point y somewhere in space. If y lies somewhere on the line xz from x to z, then $d(x,z) = d(x,y) + d(y,z)$. If y is somewhere else, then x, y and z form a triangle. And the side xz is shorter than the total of xy and yz. Therefore we get $d(x,z) < d(x,y) + d(y,z)$ in this case. In general we do not need the concept of a line in X, but we still retain the *triangle inequality* $d(x,z) \leq d(x,y) + d(y,z)$.

(6.1) Definition:
Let $X \neq \emptyset$ be any non-empty set. Then a function $d : X \times X \to \mathbb{R}$ is said to be a **metric** of X if it satisfies the following four properties for any x, y and $z \in X$

(M1) $d(x,y) \geq 0$

(M2) $d(x,y) = 0 \iff x = y$

(M3) $d(x,y) = d(y,x)$

(M4) $d(x,z) \leq d(x,y) + d(y,z)$

And in this case the ordered pair (X,d) is said to be a **metric space**. For any $r \in \mathbb{R}$ with $r > 0$ and any $x \in X$ let us then define the **open ball** of **radius** r to be the following subset $B_r(x)$ of X

$$B_r(x) := \{\, y \in X \mid d(x,y) < r \,\}$$

In case we want to emphasize the space X or metric d, under which the open ball $B_r(x)$ is taken, we also write $B_r(X,x)$ or $B_r(d,x)$ for this set. A general subset $U \subseteq X$ is said to be **open** iff any point $x \in U$ is contained in an open ball around x, that lies completely in U, formally

$$\forall\, x \in U \;\; \exists\, r > 0 \;:\; B_r(x) \subseteq U$$

(6.2) Example:

(i) On any non-empty set $X \neq \emptyset$, we can install the *trivial metric* by taking $d(x,x) := 0$ for any $x \in X$ and $d(x,y) := 1$ for any x, $y \in X$ with $x \neq y$. But as we can do this with any set, we cannot glean any information from it, which makes this metric rather worthless.

(ii) Probably the most well-known example is $X = \mathbb{R}^n$ or $X = \mathbb{C}^n$ respectively, introduced in (4.114). In this case we obtain the so-called *euclidean metric* on X by taking

$$d(x,y) := \sqrt{\sum_{k=1}^{n} (y_k - x_k)\,(\overline{y}_k - \overline{x}_k)}$$

where $x = (x_1, \ldots, x_n)$ and $y = (y_1, \ldots, y_n) \in X$. Note that in case of $X = \mathbb{R}^n$ the sum runs over $(y_k - x_k)^2$ such that $d(x,y)$ is the pythagorean distance in n-dimensional space. This is a special case of the following situation: Any inner product on a complex vector-space V induces a norm and any norm induces a metric. This metric here is inherited from the inner product

$$\langle x \mid y \rangle \;=\; \sum_{k=1}^{n} x_k \overline{y}_k$$

(iii) Let $X := \mathbb{Z}$ and fix any prime number $p \in \mathbb{Z}$. Recall, that for any $a \in \mathbb{Z}$ with $a \neq 0$ we defined $\langle a \mid p \rangle = \max\{\, n \in \mathbb{N} \mid p^n \mid a \,\}$ and this is well-defined, as $\mathbb{Z}$ is an UFD. Then we obtain a metric d_p, called the *p-adic metric* on $\mathbb{Z}$, if for any $a, b \in \mathbb{Z}$ we let

$$d_p(a,b) \;:=\; \begin{cases} 0 \text{ if } a = b \\ \dfrac{1}{\langle b-a \mid p \rangle} \text{ if } a \neq b \end{cases}$$

Thereby properties (M1) to (M3) are immediately clear. For (M4) it is fairly easy to see, that for any three numbers a, b and $c \in \mathbb{Z}$ we have $\langle c-a \mid p \rangle \geq \min\{\, \langle b-a \mid p \rangle, \langle c-b \mid p \rangle \,\}$ and thereby $d_p(a,c) \leq \max\{\, d_p(a.b), d_p(b,c) \,\}$. This is an even stronger property, than (M4).

(6.3) Remark: (viz. 1185)
If $d : X \times X \to X$ satisfies (M1), (M3) and (M4) but only $x = y \implies d(x,y) = 0$, then d is said to be a **pseudo-metric** on X. In this case we obtain an equivalence relation on X, by letting

$$x \sim y \quad :\Longleftrightarrow \quad d(x,y) \,=\, 0$$

As always, if $Q := X/\sim$ denotes the quotient set of X under this relation, then mapping X to Q under $X \twoheadrightarrow Q : x \mapsto [x] = \{\, u \in X \mid d(u,x) = 0 \,\}$ is a natural way of how to replace X by Q. And in this case we obtain a well-defined metric on Q by letting

$$Q \times Q \;\to\; \mathbb{R} \;:\; \big([x],[y]\big) \;\mapsto\; d(x,y)$$

(6.4) Proposition: (viz. 1185)

(i) Consider a metric space (X,d) and x, $y \in X$ any two points in X. Also let $r > 0$, such that $y \in B_r(x)$. If we now take $\varepsilon := (r - d(x,y))/2$, then $B_\varepsilon(y) \subseteq B_r(x)$. In particular: If $P = B_r(x)$ is any open ball of X, then P already is an open subset of X.

(ii) Consider a metric space (X,d) and let $x \neq y \in X$ be two distinct points in X. Then there exist open subsets U, $V \subseteq X$, such that (1) $x \in U$, (2) $y \in V$ and (3) $U \cap V = \emptyset$.

(iii) Let (X,d) be a metric space, $X \neq \emptyset$ and consider any point $x \in X$ and $n \in \mathbb{N}$. For $n = 0$ we take $F_0(x) := X$ and for $n \geq 1$ let $F_n(x)$ be the open ball of radius $1/n$ around x. That is we define

$$F_n(x) \;:=\; B_{\frac{1}{n}}(x) \;=\; \left\{ y \in X \;\middle|\; d(x,y) < \frac{1}{n} \right\}$$

The collection $\mathcal{F}(x) := \{ F_n(x) \mid n \in \mathbb{N} \}$ is called the **local filter** of x. And the union of all local filters of X is called the **base of balls** $\mathcal{F} := \{ F_n(x) \mid x \in X, n \in \mathbb{N} \}$ of X. Then we get all of the following properties, for any $x \in X$ and $n \in \mathbb{N}$

(1) $x \in F_n(x)$ and the set $F_n(x) \subseteq X$ is open

(2) $\mathcal{F}(x)$ is a descending chain, that is $F_{n+1}(x) \subseteq F_n(x)$

(3) The intersection of $\mathcal{F}(x)$ is $\bigcap_n F_n(x) = \{ x \}$

(4) If $U \subseteq X$ is an open set and $x \in U$, then there is some $n \in \mathbb{N}$, such that $F_n(x) \subseteq U$

(5) If $x, y \in X$ with $x \neq y$, then there is some $n \in \mathbb{N}$ such that $F_n(x) \cap F_n(y) = \emptyset$

(6) We have $X \in \mathcal{F}$ and for any $x \in X$ and any $F, G \in \mathcal{F}$ such that $x \in F \cap G$ there is some $E \in \mathcal{F}$ such that $x \in E$ and $E \subseteq F \cap G$

(6.5) Definition:

(i) Let X be an arbitrary, non-empty set. Then an function x of the form $x : \mathbb{N} \to X$ is said to be a **sequence** in X. It is usual to denote $x_n := x(n)$ and $(x_n) := x$ in this case. Also, if $P \subseteq X$ is an arbitrary subset of X, then we write $(x_n) \subseteq P$ to abbreviate

$$\forall\, n \in \mathbb{N} \quad : \quad x_n \in P$$

(ii) If (x_n) and (y_n) both are sequences in X, then (x_n) is said to be a **sub-sequence** of (y_n) iff if there is some map $k : \mathbb{N} \to \mathbb{N}$ such that the following properties (1) to (3) are satisfied. And we abbreviate this by writing $(x_n) \subseteq (y_n)$.

(1) for any $n \in \mathbb{N}$ we get $n \leq k(n)$

(2) for any $m, n \in \mathbb{N}$ we get $m < n \implies k(m) < k(n)$

(3) for any $n \in \mathbb{N}$ we get $x_n = y_{k(n)}$

Nota It is obvious, then $\subseteq$ is both reflexive [that is $(x_n) \subseteq (x_n)$] and transitive [if $(x_n) \subseteq (y_n)$ and $(y_n) \subseteq (z_n)$ then $(x_n) \subseteq (z_n)$, as well], but it is *no* partial- order however, as it is *not* not anti-symmetric.

(iii) Let X be an arbitrary, non-empty set again. Then a binary relation $\to$ between the set $\mathcal{F}(\mathbb{N}, X)$ of sequences in X and elements of X is said to be a **convergence relation** on X, iff it satisfies the following three properties

(1) If (x_n) becomes *eventually constant*, that is there are some $N \in \mathbb{N}$ and some $x \in X$ such that for any $n \geq N$ we have $x_n = x$, then we have $(x_n) \to x$.

(2) The relation $\to$ is *right-unique*, that is for any sequence (x_n) and any $x, y \in X$ we get: If both $(x_n) \to x$ and $(x_n) \to y$ then already $x = y$.

(3) If (y_n) is a sequence in X, such that $(y_n) \to y$ for some $y \in Y$ and $(x_n) \subseteq (y_n)$ is a subsequence of (y_n), then we have $(x_n) \to y$, as well.

(6.6) Definition: (viz. 1186)
Let (X, d_X) be a metric space and $(x_n) \subseteq X$ be a sequence in X (refer to (6.5) above, for a definition and notations). Also let $x \in X$ be any element, then we say that (x_n) **converges** to x (and denote this by $(x_n) \to x$) iff satisfies the following property: If we draw an open ball around x - no matter how small - then from some index on the tail of (x_n) is contained in that open ball, entirely. Formally that is

$$\forall\, \varepsilon > 0 \;\; \exists\, n(\varepsilon) \in \mathbb{N} \;:\; \forall\, n \geq n(\varepsilon) \;:\; x_n \;\in\; B_\varepsilon(x)$$

Let (Y, d_Y) be another metric space and $f : X \to Y$ be a function. Then we say that f is **continuous** iff it satisfies one of the following three equivalent properties

(a) If $V \subseteq Y$ is open, then $f^{-1}(V) \subseteq X$ is open

(b) For any $x \in X$, $\varepsilon > 0$ there is some $\delta > 0$ such that $y \in B_\delta(X, x)$ implies $f(y) \in B_\varepsilon(Y, f(x))$.

(c) If $(x_n) \subseteq X$ is a sequence and $x \in X$ is a point such that $(x_n) \to x$ converges to x, then the image $(f(x_n)) \to f(x)$ converges to $f(x)$, as well.

(6.7) Definition:
If $X \neq \emptyset$ is a non-empty set and d and D are any two metrics on X, then d is said to be **coarser** or **laxer** than D (and in this case D is said to be **finer** or **stricter** than d), iff there is some $M \in \mathbb{R}$ with $M > 0$ such that for any x, $y \in X$ we get

$$d(x, y) \;\; \leq \;\; M \cdot D(x, y)$$

In this case we write $d \leq D$. Now d and D are said to be **equivalent** if both $d \leq D$ and $D \leq d$, written as $d \sim D$. In other words, there are m, $M > 0$ such that for any x, $y \in X$ we get

$$m \cdot D(x, y) \;\; \leq \;\; d(x, y) \;\; \leq \;\; M \cdot D(x, y)$$

Nota It is clear that $\sim$ is an equivalence relation on the set of all metrics on X. Also $\leq$ is a reflexive, transitive order on the set of all metrics on X and if $d \leq D$ and $D \leq d$, then clearly $d \sim D$.

(6.8) Proposition: (viz. 1187)
Let X be a non-empty set and d and D be two metrics on X, such that $d \leq D$, that is d is laxer than D. Then we get the following three properties:

(i) If for any x, $y \in X$ we have $d(x, y) \leq M \cdot D(x, y)$ for some $M > 0$, then for any $r > 0$ the open balls with respect to D are contained in open balls with respect to d. To be precise

$$B_{r/M}(D, x) \;\; \subseteq \;\; B_r(d, x)$$

(ii) Let $\mathcal{T}_d := \{\, U \subseteq X \mid \forall\, x \in U \, \exists\, r > 0 : B_r(d, x) \subseteq U \,\}$ be collection of all open subsets of X, with respect to the metric d. Likewise let $\mathcal{T}_D$ be the collection of all sets $U \subseteq X$, that are open with respect to the metric D. Then we get

$$\mathcal{T}_d \;\; \subseteq \;\; \mathcal{T}_D$$

(iii) If $(x_n) \subseteq X$ is any sequence in X that is convergent $(x_n) \to_D x$ with respect to the metric D for some $x \in X$, then (x_n) also is convergent $(x_n) \to_d x$ to x, with respect to the metric d, formally

$$(x_n) \to_D x \quad \Longrightarrow \quad (x_n) \to_d x$$

Topological Spaces

A metric d on a set X gives rise to open balls, which in turn give rise to the notions of convergence and of open subsets. We now want to regard both of these notions in a more general setting. Let us write down some properties we have found for open sets in metric spaces and try to pry further properties from them. This is what mathematicians do all the time and here this will be especially fruitful.

(6.9) Definition:

Let X be any set and let $\mathcal{T} \subseteq \mathcal{P}(X)$ be an arbitrary collection of subsets of X. Then $\mathcal{T}$ is said to be a **topology** of X and the ordered pair $(X, \mathcal{T})$ is said to be a **topological space**, iff $\mathcal{T}$ contains $\emptyset$ and X and is closed under finite intersections and arbitrary unions. That is $\mathcal{T}$ satisfies the following four properties

(T1) $\emptyset \in \mathcal{T}$

(T2) $X \in \mathcal{T}$

(T3) $U, V \in \mathcal{T} \implies U \cap V \in \mathcal{T}$

(T4) $\mathcal{U} \subseteq \mathcal{T} \implies \bigcup \mathcal{U} \in \mathcal{T}$

In this case the $U \in \mathcal{T}$ are said to be the **open** subsets of X. And a subset $C \subseteq X$ is said to be **closed**, iff its complement is an open set. As we consider $\mathcal{T}$ to be fixed on X, we denote this by writing

$$\begin{aligned} U \subseteq X \text{ open} \quad &:\Longleftrightarrow \quad U \in \mathcal{T} \\ C \subseteq X \text{ closed} \quad &:\Longleftrightarrow \quad X \setminus C \in \mathcal{T} \end{aligned}$$

For any $x \in X$ we finally denote the $\mathcal{T}(x) := \{ U \subseteq X \text{ open} \mid x \in U \}$ and call this the **neighbourhood system** of x. More generally, for an arbitrary subset $P \subseteq X$, we denote:

$$\mathcal{T}(P) \;:=\; \{ U \subseteq X \text{ open} \mid P \subseteq U \}$$

(6.10) Remark:

Let $(X, \mathcal{T})$ be a topological space and denote $\mathcal{Z} := \{ X \setminus U \mid U \in \mathcal{T} \}$ the collection of its closed subsets. Then $\mathcal{Z}$ is a family of subsets, that inherits properties dual to (T1) to (T4). In fact we get $\emptyset$ and $X \in \mathcal{Z}$ again and $\mathcal{Z}$ is closed under finite intersections and arbitrary intersections. That is for any $C, D \in \mathbb{Z}$, we also have $C \cup D \in \mathcal{Z}$ and for any subset $\mathcal{C} \subseteq \mathcal{P}(X)$ we get

$$\mathcal{C} \neq \emptyset \quad \Longrightarrow \quad \bigcap \mathcal{C} \in \mathcal{Z}$$

Prob clearly $\emptyset = X \setminus X$ and $X = X \setminus \emptyset$ are closed subsets of X. And if $C = X \setminus U$ and $D = X \setminus V \in \mathcal{Z}$, then $C \cap D = (X \setminus U) \cap (X \setminus V) = X \setminus (U \cap V)$ and as $U \cap V \in \mathcal{T}$ this means C, $D \in \mathcal{Z}$ again. Likewise if $\mathcal{C} = \{ C_i \mid i \in I \}$ for some $C_i = X \setminus U_i$, then $\bigcap \mathcal{C} = \bigcap_i C_i = \bigcap_i (X \setminus U_i) = X \setminus (\bigcup_i U_i)$ which is closed again, as $\bigcup U_i = \bigcup \{ U_i \mid i \in I \} \in \mathcal{T}$, since all the $U_i \subseteq X$ have been open.

(6.11) Example:

(i) Any set X carries two trivial topologies: For one the set $\{ \emptyset, X \}$ is a topology on X. It resembles the case that everything is clumped together, if $x \in X$ is a point, then X is the only open set that contains it. It is called the *indiscrete topology* on X, as it is the opposite of the next example.

(ii) On the other hand the set of *all* subsets $\mathcal{T} = \mathcal{P}(X)$ forms a topology on X - this is called the *discrete topology* on X and it resembles the situation there are absolutely no connections between any points x in X. As $\{x\}$ is an open set, every point $x \in X$ stands for itself and is not connected to any other point of X. Every two points of X even share the same distance, no matter what points you take. This is the topology induced by the trivial metric in (6.2.(i)): As any point $x \in X$ is is an open ball $\{x\} = B_{1/2}(x)$ any set $P \subseteq X$ is open, as P is the union of all its points.

(iii) If (X, d) is a metric space, then we find a topology on X, by declaring that a subset $U \subseteq X$ is open, iff every point $x \in U$ already has an open ball around it, that is contained in U. That is

$$U \subseteq X \text{ open} \quad :\Longleftrightarrow \quad \forall\, x \in U \;\; \exists\, r > 0 \;:\; B_r(x) \subseteq U$$

This is a special case of (6.12.(iii)), as the open balls in a metric space are a base of a topology. The latter has been proved as property (6) in (6.4.(iii)). Nota We use the convention, that any metric space is endowed this this topology, without specifically mentioning it.

(6.12) Lemma: (viz. 1188)

(i) Let $(X, \mathcal{T})$ be a topological space and $S \subseteq X$ be any subset. Then S inherits a topology $\mathcal{T} \cap S$ (called the *relative topology* of $\mathcal{T}$) by taking the open sets

$$\mathcal{T} \cap S \;:=\; \{ U \cap S \mid U \subseteq X \text{ open} \}$$

Nota and we use the convention, that any subset S of a topological space $(X, \mathcal{T})$ is automatically endowed with its relative topology, without specifically mentioning it.

(ii) Consider an arbitrary set X and a collection $\mathcal{Z} \subseteq \mathcal{P}(X)$ of subsets of X, that satisfies the following four properties [that are dual to properties (T1) to (T4) of a topology]

(C1) $\emptyset \in \mathcal{Z}$

(C2) $X \in \mathcal{Z}$

(C3) $C, D \in \mathcal{Z} \implies C \cup D \in \mathcal{Z}$

(C4) $\emptyset \neq \mathcal{C} \subseteq \mathcal{Z} \implies \bigcap \mathcal{C} \in \mathcal{Z}$

Then $\mathcal{Z}$ are the closed sets of a topology on X. That is we obtain a topology $\mathcal{T}$ on X by taking the complements of the sets of $\mathcal{Z}$ as open sets in X, formally

$$\mathcal{T} \;:=\; \{\, X \setminus C \mid C \in \mathcal{Z} \,\}$$

(iii) Consider an arbitrary set X and a collection $\mathcal{B} \subseteq \mathcal{P}(X)$ of subsets of X. Then $\mathcal{B}$ is said to be a **base** of a topology, iff it satisfies the following two properties

(B1) $X = \bigcup \mathcal{B}$

(B2) For any $x \in X$ and any $B, C \in \mathcal{B}$ such that $x \in B \cap C$ there is some $A \in \mathcal{B}$ such that $x \in A$ and $A \subseteq B \cap C$.

Then we obtain a topology $\mathcal{T}$ on X (called the topology *induced* by $\mathcal{B}$) by defining, that a subset $U \subseteq X$ is open, iff (a) any point $x \in U$ is contained in a base set $B \in \mathcal{B}$ that in turn is contained in U again or equivalently, iff (b) U is the union of some collection of base sets B_i (where I may be empty, finite or infinite). Formally that is

$$\begin{aligned} U \subseteq X \text{ open} \quad &:\Longleftrightarrow \quad \forall\, x \in U \;\; \exists\, B \in \mathcal{B} \;:\; x \in B \subseteq U \\ &\Longleftrightarrow \quad \exists\, \{\, B_i \mid i \in I \,\} \subseteq \mathcal{B} \text{ such that } U = \bigcup_{i \in I} B_i \end{aligned}$$

Nota If conversely $\mathcal{T} \subseteq \mathcal{P}(X)$ already is a topology on X and $\mathcal{B} \subseteq \mathcal{T}$ satisfies (one of) these properties (a) or (b), then we also get (B1), due to (T2) and (B2) due to (T3).

(iv) Let X be an arbitrary set and $I \neq \emptyset$ be a non-empty index-set. Suppose for any $i \in I$ we are given a topology $\mathcal{T}_i$ on X. Then their intersection $\mathcal{T} := \bigcap \mathcal{T}_i$ is a topology on X, as well.

Nota this allows us to define the topology on X generated by *any* subset of $\mathcal{P}(X)$, but it is much preferable to start with a basis of a topology, as in this case we get an explicit description of the topology, as we did in (iii).

(v) Let X and Y be any sets, where $(Y, \mathcal{T}_Y)$ is a topological space and consider a function $f : X \to Y$. Then we obtain a topology $f^{-1}(\mathcal{T}_Y)$ on X (called the *pull-back* of $\mathcal{T}_Y$) by defining

$$f^{-1}(\mathcal{T}_Y) \;:=\; \left\{ f^{-1}(V) \mid V \subseteq Y \text{ open} \right\}$$

(vi) Let I be any non-empty index set and for any $i \in I$ consider a topological space $(X_i, \mathcal{T}_i)$. Then we find a topology $\prod_i \mathcal{T}_i$ on the cartesian product set $\prod_i X_i$ (called the *box topology* of the $\mathcal{T}_i$) by defining that a subset V is open, iff any point $(x_i) \in V$ is contained in a set of the form $U := \prod_i U_i$ where $U_i \subseteq X_i$ is open for any $i \in I$, such that U is contained in V again, formally

$$V \subseteq \prod_{i \in I} X_i \text{ open} \quad :\Longleftrightarrow \quad \forall\, (x_i) \in V \;\; \exists\, (U_i) \;:\; U_i \subseteq X_i \text{ open and } (x_i) \in \prod_{i \in I} U_i \subseteq V$$

Nota and we use the convention, that the product space $\prod_i X_i$ is automatically endowed with the box topology $\prod_i \mathcal{T}_i$, without specifically mentioning it.

(6.13) Remark:
The relative topology of (6.12.(i)) makes the relation "is an open subset of" transitive. That is if $(X, \mathcal{T})$ is a topological space, $V \subseteq X$ is open and $U \subseteq V$ is open [in the sense of $(V, \mathcal{T} \cap V)$], then $U \subseteq X$ is open, as well. The same is true for the "is a closed subset of" relation. If $D \subseteq X$ is closed and $C \subseteq D$ is closed, then $C \subseteq X$ is closed, too.

Prob By definition $U \subseteq V$ is open, iff there is some $U' \subseteq X$ such that $U = U' \cap V$. As V is open and the intersection of two open sets is open again, we find $U \subseteq X$ to be an open subset of X. Likewise $C \subseteq D$ is closed, iff $C = D \setminus U$ for some $U \subseteq D$ open. That is $U = U' \cap D$ again and hence $C = D \setminus (U' \cap D) = D \setminus U' = D \cap (X \setminus U')$. Thus $C \subseteq X$ is closed, as D and $X \setminus U'$ are closed and the intersection thereby is closed, too.

(6.14) Remark:
In (6.12.(vi)) there is an alternate topology on the cartesian product $\prod_i X_i$ called the *product topology*. It is defined by using the following set as the base for the product topology

$$\mathcal{B} \;=\; \left\{ \prod_{i \in I} U_i \;\middle|\; \begin{array}{l} \forall\, i \in I : U_i \subseteq X_i \text{ open} \\ \#\{\, i \in I \mid U_i \neq X_i \,\} < \infty \end{array} \right\}$$

It is obvious that $\mathcal{B}$ is closed under finite intersections and thereby satisfies properties (1) and (2) in (6.12.(iii)). Thus V is an open set in the product topology iff it satisfies

$$V \subseteq \prod_{i \in I} X_i \text{ open} \quad :\Longleftrightarrow \quad \forall\, (x_i) \in V \;\; \exists \prod_{i \in I} U_i \in \mathcal{B} \text{ such that } (x_i) \in \prod_{i \in I} U_i \subseteq V$$

From this it is clear that in case of a finite set I the box topology equals the product topology. If I is infinite however, then the product topology only is a subset of the box topology (the box topology is *finer* than the product topology).

(6.15) Definition:
Let $(X, \mathcal{T})$ be a topological space and consider any subset $P \subseteq X$. Then we define the **interior** of P to be the largest open subset of X, that is contained in P, formally

$$P^\circ \;:=\; \bigcup \{\, U \subseteq X \text{ open} \mid U \subseteq P \,\} \;=\; \{\, x \in P \mid \exists\, U \subseteq X \text{ open} : x \in U \subseteq P \,\}$$

We will prove the equality of these sets (and all the other properties mentioned in this definition) in remark (6.16) below. Likewise we define the **closure** of P to be the smallest closed subset of X that contains P. That is we define

$$\overline{P} \;:=\; \bigcap \{\, C \subseteq X \text{ closed} \mid P \subseteq C \,\} \;=\; X \setminus \big(X \setminus P\big)^\circ$$

Then we have $P^\circ \subseteq P \subseteq \overline{P}$ and thereby we may define the **border** of P to be the closure of P without its interior - which is a closed subset of X. Formally again

$$\partial P \;:=\; \overline{P} \setminus P^\circ$$

(6.16) Remark: (viz. 1187)
Let $(X, \mathcal{T})$ be any topological space, and $P \subseteq X$ be any subset of X, then the identities for P° and $\overline{P}$ in definition (6.15) are true and we additionally obtain

(i) $P^\circ \subseteq X$ is open

(ii) $\overline{P} \subseteq X$ is closed

(iii) $\partial P \subseteq X$ is closed

(iv) $U \subseteq X$ is open, iff $U = U^\circ$

(v) $C \subseteq X$ is closed, iff $C = \overline{C}$

(vi) $P^\circ \subseteq P \subseteq \overline{P}$

(vii) $\overline{P} = P^\circ \cup \partial P$

(viii) If $C \subseteq X$ is closed and $P \subseteq C$, then $\overline{P} \subseteq C$

(ix) If for any $x \in V$ there is some $U \in \mathcal{T}(x)$ with $U \subseteq V$, then $V \subseteq X$ is open

(x) Let $S \subseteq X$ be any subset and regard S in the relative topology $\mathcal{T} \cap S$. If now $P \subseteq S$ is any subset we take $\mathrm{cl}_S(P)$ to be the closure of P in the relative topology $\mathcal{T} \cap S$ and $\mathrm{cl}_X(P)$ to be the closure of $P \subseteq X$ in the topology $\mathcal{T}$. And thereby we get

$$\mathrm{cl}_S(P) \;=\; \mathrm{cl}_X(P) \cap S$$

Nota the like statement for the interior of P is false, in general. As a counterexample regard $P = \{\, (x,0) \mid 0 \leq x < 1 \,\} \subseteq S$ where $S = \{\, (x,0) \mid x \in \mathbb{R} \,\}$ and $X = \mathbb{R}^2$. If we regard P as a subset of S, then the interior of P is given to be $\mathrm{it}_S(P) = \{\, (x,0) \mid 0 < x < 1 \,\}$ whereas for $P \subseteq X$ the interior is $\mathrm{it}_X(P) = \emptyset$.

Finiteness conditions are of great importance in algebra and analysis. The most common finiteness condition in topology is *compactness*. There is an entire world of notions and theorems concerning compactness and its relations to other properties, but as we are concerned with algebra, not analysis, we only introduce those notions we truly need.

(6.17) Definition:
Let $(X, \mathcal{T})$ be a topological space. Then a subset $K \subseteq X$ is said to be **compact** iff every open cover of K has a finite sub-cover. Formally: If $\{\, U_i \mid i \in I \,\} \subseteq \mathcal{T}$ is an arbitrary collection of open sets, then we get the following implication

$$K \subseteq \bigcup_{i \in I} U_i \quad \Longrightarrow \quad \exists\, \Omega \subseteq I \text{ finite, such that } K \subseteq \bigcup_{i \in \Omega} U_i$$

And a subset $P \subseteq X$ is said to be **precompact**, iff its closure $\overline{P} \subseteq X$ is a compact set. The topological space $(X, \mathcal{T})$ is said to be **compact**, iff the entire space X is compact. And $(X, \mathcal{T})$ is said to be **locally compact**, iff for every point $x \in X$ there is an open neighbourhood $U \in \mathcal{T}(x)$ such that $\overline{U}$ is a compact set.

(6.18) Proposition: (viz. 1190)

(i) If $(X, \mathcal{T})$ is a compact topological space and $C \subseteq X$ is a closed subset, then C is compact, as well.

(ii) If $(X, \mathcal{T})$ is any topological space and $K_1, \ldots, K_n \subseteq X$ are finitely many compact subsets of X, then the union $K_1 \cup \cdots \cup K_n$ of these sets is compact again.

(6.19) Definition:
Let $(X, \mathcal{T})$ be a topological space, then a function of the form $\mathcal{F} : \mathbb{N} \times X \to \mathcal{P}(X)$, that assigns any pair $(n, x) \in \mathbb{N} \times X$ a subset $F_n(x) := \mathcal{F}(n, x) \subseteq X$ is said to be a **system of local filters**, iff it satisfies the following four properties for any $n \in \mathbb{N}$ and any $x \in X$

(F1) $F_n(x) \in \mathcal{T}(x)$ is an open neighbourhood

(F2) The $F_n(x)$ form a descending chain: $F_{n+1}(x) \subseteq F_n(x)$

(F3) If $U \in \mathcal{T}(x)$, then there is some $n \in \mathbb{N}$ such that $F_n(x) \subseteq U$

(F4) For any $x, y \in X$ with $x \neq y$ there is an $n \in \mathbb{N}$, such that $F_n(x) \cap F_n(y) = \emptyset$

In this case the collection $\mathcal{F}(x) := \{ F_n(x) \mid n \in \mathbb{N} \} \subseteq \mathcal{T}$ is said to be the *local filter* of $\mathcal{F}$ at $x \in X$. Now, if $\mathcal{F}$ is a system of local filters, then we define a convergence relation [this will be proved in (6.21.(iii)] on X: If $(x_n) \subseteq X$ is a sequence and $x \in X$ is a point, then we define

$$(x_n) \to_{\mathcal{F}} x \quad :\Longleftrightarrow \quad \forall\, m \in \mathbb{N}\ \exists\, n(m) \in \mathbb{N}\ :\ \forall\, n \geq n(m)\ :\ x_n \in F_m(x)$$

Nota In a system of local filters $\mathcal{F}$ the sets $\mathcal{F}(x)$ are *not* filters in the sense of definition (6.22), not even prefilters, but chains ordered under inclusion $\subseteq$. And as such $\mathcal{F}(x)$ is what is called a *basis* of the neighbourhood filter $\mathcal{N}(x)$. That is $\mathcal{F}(x)$ gives rise to $\mathcal{N}(x)$ under the construction in (6.23.(iii)).

(6.20) Example:

(i) If (X, d) is a metric space, then we obtain a system of local filters on X, by taking $F_n(x) := B_{1/n}(x)$ as we have seen in (6.4.(iii)), properties (1), (2), (4) and (5). And the convergence relation on X, as a metric space, is precisely the convergence relation of this system of local filters. It can be rewritten as

$$\forall\, \varepsilon > 0\ \exists\, n(\varepsilon) \in \mathbb{N}\ :\ \forall\, n \geq n(\varepsilon)\ :\ d(x_n, x) < \varepsilon$$

(ii) Let $(R, +, \cdot)$ be a commutative ring and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be an ideal, such that $\bigcap_n \mathfrak{a}^n = 0$. Then we obtain a system of local filters on R by letting $F_n(x) := x + \mathfrak{a}^n$. The topology on R thereby is called the **$\mathfrak{a}$-adic** topology, which is defined to be

$$U \subseteq R \text{ open} \quad :\Longleftrightarrow \quad \forall\, u \in U\ \exists\, n \in \mathbb{N}\ :\ u + \mathfrak{a}^n \subseteq U$$

Prob Clearly $x \in x + \mathfrak{a}^n$ and if $u \in x + \mathfrak{a}^n$ then $u - x \in \mathfrak{a}^n$. Thus $u + \mathfrak{a}^n = x + (u - x) + \mathfrak{a}^n = x + \mathfrak{a}^n$ such that $F_n(u) = F_n(x)$. In particular $F_n(x)$ is open and we have (F1). Now (F2) is clear from $\mathfrak{a}^{n+1} \subseteq \mathfrak{a}^n$ and (F3) is just the definition of the topology. For (F4) we consider $x \neq y$ and take $n \in \mathbb{N}$ such that $y - x \notin \mathfrak{a}^n$ which is possible, as $\bigcap \mathfrak{a}^n = 0$. If we then had $z \in (x + \mathfrak{a}^n) \cap (y + \mathfrak{a}^n)$ then $z - x \in \mathfrak{a}^n$ and $z - y \in \mathfrak{a}^n$ and thereby $y - x = (z - x) - (z - y) \in \mathfrak{a}^n$ too, a contradiction. Thus $(x + \mathfrak{a}^n) \cap (y + \mathfrak{a}^n) = \emptyset$, which is property (F4).

The next proposition studies the connection between topologies and systems of local filters. (6.21.(i)) tells us, that it is possible to reconstruct the topology $\mathcal{T}$ of X from the system of local filters $\mathcal{F}$. By (6.21.(vi)) we can even reconstruct the topology from the convergence relation induced by $\mathcal{F}$. However not all topological spaces admit a system of local filters and hence "topology" is the more general concept. (6.21.(ii)) classifies, which topologies admit a system of local filters - and which don't.

We need to fix a system of local filters on X to construct a convergence relation. However in (6.21.(iv)) it turns out, that the convergence relation actually does not depend on the specific system of filters $\mathcal{F}$ chosen. In this sense the convergence relation only depends on the underlying topology $\mathcal{T}$ on X. You might want to think of this in the following way: The absolute value of distance may be different, but the topology already determines, what is close by and what is far away and thereby convergence.
We will encounter this again in the setting of normed spaces. In a finite-dimensional normed space, all norms are equivalent and hence they all induce the same convergence relation. However, there are a multitude of norms out there, that induce different metrics.

(6.21) Lemma: (viz. 1190)

(i) If $(X, \mathcal{T})$ is a topological space and $\mathcal{F}$ is a system of local filters of X, then for an arbitrary subset $U \subseteq X$, the following two statements are equivalent

 (a) $U \subseteq X$ is open

 (b) For any $x \in U$ there is some $n \in \mathbb{N}$, such that $F_n(x) \subseteq U$

(ii) A topological space $(X, \mathcal{T})$ admits a system of local filters $\mathcal{F}$, if and only if the topology satisfies both of the following two properties

 (1) $(X, \mathcal{T})$ is a *Hausdorff-space*, that is for any two points $x, y \in X$ with $x \neq y$ there are open subsets $U, V \subseteq X$ such that $x \in U$ and $y \in V$, but $U \cap V = \emptyset$.

 (2) $(X, \mathcal{T})$ admits *countable neighbourhood bases*: For any $x \in X$ there is a set $\mathcal{B}(x) \subseteq \mathcal{T}(x)$ such that $\mathcal{B}(x)$ is countable and for any $U \in \mathcal{T}(x)$ there is some $B \in \mathcal{B}(x)$ such that $B \subseteq U$.

(iii) If $(X, \mathcal{T})$ is a topological space and $\mathcal{F}$ is a system of local filters of X, then we obtain a convergence relation $\to_{\mathcal{F}}$ on X by defining - for any sequence $(x_n) \subseteq X$ and point $x \in X$

$$(x_n) \to_{\mathcal{F}} x \quad :\Longleftrightarrow \quad \forall\, m \in \mathbb{N}\ \exists\, n(m) \in \mathbb{N} \,:\, \forall\, n \geq n(m) \,:\, x_n \in F_m(x)$$

(iv) If $(X, \mathcal{T})$ is a topological space and $\mathcal{E}$ and $\mathcal{F}$ are any two systems of local filters on X, then theses convergence relations are identical. That is for any sequence $(x_n) \subseteq X$ and $x \in X$, we get

$$(x_n) \to_{\mathcal{E}} x \iff (x_n) \to_{\mathcal{F}} x$$

Nota as the convergence relations actually do not depend on the specific system of local filters used, we will often omit the index $\mathcal{F}$ and write $(x_n) \to x$ only.

(v) If $(X, \mathcal{T})$ is a topological space, $\mathcal{F}$ is a system of local filters of X and $P \subseteq X$ is any subset, then closure of P is precisely the set of limits of convergent sequences in P, formally that is

$$\overline{P} = \left\{ x \in X \;\middle|\; \begin{array}{l} \exists\, (x_n) \subseteq P \text{ such that} \\ (x_n) \to_{\mathcal{F}} x \end{array} \right\}$$

(vi) If $(X, \mathcal{T})$ is a topological space, $\mathcal{F}$ is a system of local filters of X and $C \subseteq X$ is any subset, then the following two statements are equivalent

(a) $C \subseteq X$ is closed

(b) For any $(x_n) \subseteq C$ with $(x_n) \to_{\mathcal{F}} x$ we get $x \in C$

6.2 Continuous Maps

Filters are the next level of generalisation, when it comes to convergence. They are the right way to deal, with non-Hausdorff spaces. The general idea is, that the neighbourhood system $\mathcal{T}(x)$ is centred at x, that is in a Hausdorff space $(X,\mathcal{T})$ we always have $\bigcap \mathcal{T}(x) = \{ x \}$. In general this need not be true - just look at the indiscrete topology. The prototype of a filter is the neighbourhood filter $\mathcal{N}(x)$, introduced in (6.23.(i)). It also satisfies $\bigcap \mathcal{N}(x) = \{ x \}$ in a Hausdorff space. In general topology a filter $\mathcal{F}$ is said to converge $\mathcal{F} \to x$ against $x \in X$, iff $\mathcal{N}(x) \subseteq \mathcal{F}$, as in this case $\bigcap \mathcal{F} \subseteq \bigcap \mathcal{N}(x)$ which is thought to be the closest you can get towards a limit. As we will not need these concepts however, we will only scratch the surface, here.

(6.22) Definition:
Let X be any non-empty set, then a collection $\mathcal{F} \subseteq \mathcal{P}(X)$ of subsets of X is said to be a **prefilter**, iff it satisfies the following three properties

(1) $\mathcal{F} \neq \emptyset$ is non-empty

(2) for any $F \in \mathcal{F}$ we have $F \neq \emptyset$

(3) if $F \subseteq \mathcal{F}$ and $P \subseteq X$ is a arbitrary subset of X, then $F \subseteq P \implies P \in \mathcal{F}$ already

The latter property (3) is also known as the *upward closure property* of $\mathcal{F}$. And a prefilter that contains X and is also closed under finite intersections is said to be a **filter**. That is a filter $\mathcal{F}$ also satisfies

(1') $X \in \mathcal{F}$

(4) for any $E, F \in \mathcal{F}$ we have $E \cap F \in \mathcal{F}$, as well

(6.23) Proposition: (viz. 1192)

(i) If $(X,\mathcal{T})$ is any topological space and $x \in X$ is a point in X, then we obtain a filter $\mathcal{N}(x)$ - the so-called **neighbourhood-filter** of x - by letting

$$\mathcal{N}(x) \;:=\; \{ N \subseteq X \mid \exists\, U \in \mathcal{T}(x) : U \subseteq N \}$$

(ii) If $f : X \twoheadrightarrow Y$ is any surjective function between the sets X and Y and $\mathcal{F}$ is a (pre)filter on X, then the image $f(\mathcal{F}) := \{ f(F) \mid F \in \mathcal{F} \}$ is a (pre)filter on Y, again.

Nota This proposition includes: Given an arbitrary function $f : X \to Y$ we get a surjective function $f : X \twoheadrightarrow f(X)$. Thereby $f(\mathcal{F})$ is a (pre)filter on the image $f(X)$, but not necessarily on Y.

(iii) If X is any set, $x \in X$ is any point in X and $\mathcal{B} \subseteq \mathcal{P}(X)$ is a collection of subsets of X that satisfies (1) $\mathcal{B} \neq \emptyset$, (2) for any $B \in \mathcal{B}$ we get $x \in B$ and (3) for any $B, C \in \mathcal{B}$ there is some $A \in \mathcal{B}$ such that $A \subseteq B \cap C$, then we obtain a filter $\mathcal{F}$ on X, by letting

$$\mathcal{F} \;:=\; \{ F \subseteq X \mid \exists\, B \in \mathcal{B} : B \subseteq F \}$$

Nota if $\mathcal{F} = \{ F_n(x) \mid x \in X, n \in \mathbb{N} \}$ is a system of local filters on $(X, \mathcal{T})$ and $\mathcal{F}(x)$ is the local filter at $x \in X$, that is $\mathcal{F}(x) = \{ F_n(x) \mid n \in \mathbb{N} \}$, then it is plain to see that this construction yields the neighbourhood filter in (i). That is we get

$$\mathcal{N}(x) \;=\; \{ N \subseteq X \mid \exists\, n \in \mathbb{N} : F_n(x) \subseteq N \}$$

Continuous Maps

Homomorphisms φ respect the algebraic structure of the objects involved. E.g. we require $\varphi(x+y) = \varphi(x) + \varphi(y)$. Continuous functions f are the analogue of homomorphisms in topological spaces, as they respect the topological structure of the spaces involved. However the image of a function is hard to control, the preimage is far easier. Thus the standard definition of f being continuous requires $f^{-1}(V)$ to be an open set for any open set V. Yet there are lots of reformulations of this, (f) is probably the one that appeals best to the intuition of "nearby points remain nearby, when mapped under f".

(6.24) Definition: (viz. 1193)
Let $(X, \mathcal{T}_X)$ and $(Y, \mathcal{T}_Y)$ be any two topological spaces and consider a function $f : X \to Y$. Then f is said to be **continuous** ($\mathcal{T}_X$-$\mathcal{T}_Y$-continuous, to be precise), iff it satisfies one of the following seven equivalent properties (a) to (g)

(a) for any $V \subseteq Y$ open, we get $f^{-1}(V) \subseteq X$ open

(b) for any $D \subseteq Y$ closed, we get $f^{-1}(D) \subseteq X$ closed

(c) for any subset $Q \subseteq Y$, we get $f^{-1}\big(Q^\circ\big) \subseteq f^{-1}(Q)^\circ$

(d) for any subset $Q \subseteq Y$, we get $\overline{f^{-1}(Q)} \subseteq f^{-1}\big(\overline{Q}\big)$

(e) for any subset $P \subseteq X$, we get $f\big(\overline{P}\big) \subseteq \overline{f(P)}$

(f) for any $x \in X$ and $V \in \mathcal{T}\big(f(x)\big)$ there is some $U \in \mathcal{T}(x)$ such that $f(U) \subseteq V$

(g) For any $x \in X$ let us denote $\mathcal{N}(x) := \{ M \subseteq X \mid \exists\, U \in \mathcal{T}(x) : U \subseteq M \}$ the neighbourhood filter of $x \in X$ and $\mathcal{N}(f(x)) := \{ N \subseteq f(X) \mid \exists\, V \in \mathcal{T}(f(x)) : V \cap f(X) \subseteq N \}$ the neighbourhood filter of $f(x) \in f(X) \subseteq Y$. Then for any (pre)filter $\mathcal{F}$ on X we get the implication

$$\mathcal{N}(x) \subseteq \mathcal{F} \implies \mathcal{N}\big(f(x)\big) \subseteq f(\mathcal{F}) := \{ f(F) \mid F \in \mathcal{F} \}$$

(6.25) Proposition: (viz. 1195)
Let $(X, \mathcal{T}_X)$ and $(Y, \mathcal{T}_Y)$ be topological spaces and $f : X \to Y$ be any function. Also let $\mathcal{E} \subseteq \mathcal{T}_X$ be a local system of filters on X and $\mathcal{F} \subseteq \mathcal{T}_Y$ be a local system of filters on Y. Then the following three statements are equivalent

(a) $f : X \to Y$ is continuous

(b) for any $n \in \mathbb{N}$ and any $x \in X$ there is some $m \in \mathbb{N}$ such that $f(E_m(x)) \subseteq F_n(f(x))$

(c) for any $(x_n) \subseteq X$ and $x \in X$ we get $(x_n) \to_{\mathcal{E}} x \implies (f(x_n)) \to_{\mathcal{F}} f(x)$

It is worthwhile to compare the above proposition (6.25) to the case of metric spaces (6.6): We see that we have just found a direct generalization of continuous maps between metric spaces, to the case of topological spaces, that are hausdorff and have countable neighbourhood bases - these are precisely the topological spaces, that admit a system of local filters, according to (6.21.(ii)).

(6.26) Definition:
A map $\Phi : X \to Y$ is said to be a **homeomorphism** iff (1) it is bijective, (2) it is continuous and (3) the inverse map $\Phi^{-1} : Y \to X$ is continuous, too. Two topological spaces are said to be **homeomorphic**, iff there is a homeomorphism f from X to Y. In this case we write

$$(X, \mathcal{T}_X) \approx (Y, \mathcal{T}_Y) \quad :\Longleftrightarrow \quad \exists\, \Phi : X \to Y \text{ homeomorphism}$$

Nota the property of being homeomorphic is analogous to the concept of being isomorphic in algebra: If X and Y are homeomorphic, then the homeomorphism Φ transfers any topological property from X to Y and vice versa. Hence these spaces have identical topological properties, like being hausdorff, being compact, admitting a system of local filters and so on - you name it.

(6.27) Definition:
Let $(X, \mathcal{T}_X)$ and $(Y, \mathcal{T}_Y)$ be any topological spaces and consider any map $f : X \to Y$ between them. Then f is said to be **open**, iff it satisfies one of the following two equivalent properties

(a) for any $U \subseteq X$ open, the image $f(U) \subseteq Y$ is open

(b) for any $x \in X$ and any $U \in \mathcal{T}(x)$ we have $f(U) \in \mathcal{T}(f(x))$

Analogously, for any $x \in X$, let $\mathcal{Z}(x) := \{\, C \subseteq X \text{ closed} \mid x \in C \,\}$ denote the collection of closed sets containing x. Then f is said to be **closed**, iff it satisfies one of the following two equivalent properties

(a) for any $C \subseteq X$ closed, the image $f(U) \subseteq Y$ is closed

(b) for any $x \in X$ and any $C \in \mathcal{Z}(x)$ we have $f(C) \in \mathcal{Z}(f(x))$

Prob the direction (a) $\implies$ (b) is clear: If $U \in \mathcal{T}(x)$, then by (a) $f(U) \subseteq Y$ is open again. And whenever $x \in U$, then $f(x) \in f(U)$ is granted. Conversely for (b) $\implies$ (a): If $U = \emptyset$, then $f(U) = \emptyset$ is open again. And if $U \neq \emptyset$ then $U \in \mathcal{T}(x)$ for some $x \in X$. Thus by (b) $f(U) \in \mathcal{T}(f(x))$ and in particular $f(U)$ is open. For closed maps we can argue in exactly the same way.

(6.28) Example:

(i) Consider the function $f : \mathbb{R} \to \mathbb{R}$ where $f(x) := \mathrm{int}(x) = \max\{\, k \in \mathbb{Z} \mid k \leq x \,\}$. Then f is closed as its image is a subset of $\mathbb{Z} \subseteq \mathbb{R}$ which consists of discrete points. But it is not continuous, the preimage of $]0.5, 1.5[$ is $[1, 2[$ which is neither open nor closed.

(ii) The map $\pi_1 : \mathbb{R}^2 \to \mathbb{R} : (x, y) \to x$ is continuous and open (this will be proved below), but not closed. The hyperbola $H := \{\, (x, y) \in \mathbb{R}^2 \mid xy = 1 \,\}$ is closed in $\mathbb{R}^2$, as it is the preimage of $\{1\}$ of the continuous function $f(x, y) := xy$. But $\pi_1(H) = \mathbb{R}^*$ which is an open subset of $\mathbb{R}$.

(6.29) Proposition: (viz. 1195)

(i) If $(X, \mathcal{T}_X)$ and $(Y, \mathcal{T}_Y)$ are any topological spaces and $y_0 \in Y$ is a fixed point, then the constant map $X \to Y : x \mapsto y_0$ is continuous.

(ii) Let X be a non-empty set and $\mathcal{T}_1$ and $\mathcal{T}_2$ be topologies on X. We regard the identity $\mathbb{1}_X : X \to X$ as a map from $(X, \mathcal{T}_1)$ to $(X, \mathcal{T}_2)$, then $\mathbb{1}_X$ is $\mathcal{T}_1$-$\mathcal{T}_2$-continuous, if and only if $\mathcal{T}_2 \subseteq \mathcal{T}_1$.

(iii) If $(X, \mathcal{T}_X)$, $(Y, \mathcal{T}_Y)$ and $(Z, \mathcal{T}_Z)$ are topological spaces and $f : X \to Y$ and $g : Y \to Z$ are continuous functions, then the composition $gf : X \to Z$ is continuous again.

(iv) Let $(X, \mathcal{T}_X)$ and $(Y, \mathcal{T}_Y)$ be topological spaces, where $\mathcal{T}_Y$ is induced by the basis $\mathcal{B} \subseteq \mathcal{P}(Y)$, as defined in (6.12.(iii)). If now $f : X \to Y$ is a function, such that $f^{-1}(B) \subseteq X$ is open for any $B \subseteq \mathcal{B}$, then f already is continuous.

(v) Let $(X, \mathcal{T}_X)$ and $(Y, \mathcal{T}_Y)$ be topological spaces, where $\mathcal{T}_X$ is induced by the basis $\mathcal{A} \subseteq \mathcal{P}(X)$, as defined in (6.12.(iii)). If now $f : X \to Y$ is a function, such that $f(A) \subseteq Y$ is open for any $A \subseteq \mathcal{A}$, then f already is open.

(vi) Let $(X, \mathcal{T}_X)$ and $(Y, \mathcal{T}_Y)$ be topological spaces, where $\mathcal{T}_X$ is induced by the basis $\mathcal{A} \subseteq \mathcal{P}(X)$, as defined in (6.12.(iii)). If now $f : X \hookrightarrow Y$ is an injective function, such that $f(X \setminus A) \subseteq Y$ is closed for any $A \subseteq \mathcal{A}$, then f already is closed.

(vii) If $(X, \mathcal{T}_X)$ and $(Y, \mathcal{T}_Y)$ are topological spaces and $\Phi : X \to Y$ is any function, then the following three properties of Φ are equivalent

(a) Φ is a homeomorphism

(b) Φ is bijective, continuous and open

(b) Φ is bijective, continuous and closed

(viii) If $(X, \mathcal{T}_X)$ and $(Y, \mathcal{T}_Y)$ are any topological spaces, $K \subseteq X$ is a compact set and $f : X \to Y$ is a continuous map, then the image $f(K) \subseteq Y$ is a compact set, as well.

(ix) Let I be a non-empty index set and for any $i \in I$ let $(X_i, \mathcal{T}_i)$ be a topological space. We bestow the cartesian product $\prod_i X_i$ with the box or product topology (your choice). Then for any $j \in I$ the canonical projection π_j is both continuous and open

$$\pi_j \,:\, \prod_{i \in I} X_i \twoheadrightarrow X_j \,:\, (x_i) \mapsto x_j$$

(x) Let I be a non-empty index set and for any $i \in I$ let $(X_i, \mathcal{T}_i)$ be a topological space. We bestow the cartesian product $\prod_i X_i$ with the product topology. Fix any $j \in I$ and for any $i \in I$ with $i \neq j$ some $a_i \in X_i$. Then the embedding ι_j of X_j into the cartesian product is continuous, where

$$\iota_j \,:\, X_j \hookrightarrow \prod_{i \in I} X_i \,:\, x_j \mapsto \left(\begin{cases} x_j \text{ if } i = j \\ a_i \text{ if } i \neq j \end{cases} \right)$$

(xi) *Universal property of the product topology*: Let I be a non-empty index set and for any $i \in I$ let $(Y_i, \mathcal{T}_i)$ be a topological space. We bestow the cartesian product $\prod_i Y_i$ with the product topology. Also let $(X, \mathcal{T})$ be a topological space and for any $i \in I$ let $f_i : X \to Y_i$ be a continuous function. Then the product function $\prod_i f_i$ is continuous again, where

$$\prod_{i \in I} f_i \ : \ X \to \prod_{i \in I} X_i \ : \ x \mapsto \big(f_i(x)\big)$$

(6.30) Proposition: (viz. 1199)
Gluing Lemma: Let $(X, \mathcal{T}_X)$ and $(Y, \mathcal{T}_Y)$ be topological spaces and consider an arbitrary index set I. Suppose for any $i \in I$ we are given a subset $X_i \subseteq X$ such that X is covered by the X_i

$$X \ = \ \bigcup_{i \in I} X_i$$

Further suppose that for any $i \in I$ we are given continuous maps $f_i : X_i \to Y$ (where X_i is regarded in the relative topology $\mathcal{T}_X \cap X_i$) such that for any $i, j \in I$ we get

$$f_i\big|_{X_i \cap X_j} \ = \ f_j\big|_{X_i \cap X_j}$$

Then the functions f_i can be patched together to a single, well-defined function $f : X \to Y$ such that for any $i \in I$ we get $f_i = f\big|_{X_i}$ by virtue of

$$f \ : \ X \to Y \ : \ x \mapsto f_i(x) \quad \text{where} \quad x \in X_i$$

We now distinguish two variants: If (i) $X_i \subseteq X$ is open for any $i \in I$ or (ii) if I is finite and $X_i \subseteq X$ is closed for any $i \in I$ then the patchwork function f is continuous.

(6.31) Proposition: (viz. 1198)

(i) Let I be any non-empty index set and for any $i \in I$ consider a topological space $(X_i, \mathcal{T}_i)$. For any $i \in I$ let $f_i : X_i \to Y$ be an arbitrary map, to some fixed set Y. Then we can install a topology $\mathcal{T}_Y$ on Y, called the *final topology*, on Y by defining

$$V \subseteq Y \text{ open} \quad :\Longleftrightarrow \quad \forall\, i \in I \, : \, f_i^{-1}(V) \subseteq X_i \text{ open}$$

And thereby all the $f_i : X_i \to Y$ become continuous maps. Also, if $(Z, \mathcal{T}_Z)$ is another topological space and $g : Y \to Z$ is any map, then the following two statements are equivalent

(a) $g : Y \to Z$ is continuous

(b) $\forall\, i \in I$ the composition $gf_i : X_i \to Z$ is continuous

(ii) A special case of (i) is the *quotient topology*: If $(X, \mathcal{T})$ is any topological space and $\sim$ is an equivalence relation on X, then we can install a topology on the quotient set $X/\sim$ by defining

$$V \subseteq Y \text{ open} \quad :\Longleftrightarrow \quad \{\, x \in X \mid [x] \in V \,\} \subseteq X \text{ open}$$

That is the final topology induced by the canonical map $\varrho : x \mapsto [x]$, in particular ϱ is continuous. Also for any subset $P \subseteq X$ we get $\varrho^{-1}(\varrho(P)) = \bigcup \{ [p] \mid p \in P \}$. And thereby, for any $x \in X$ the equivalence class $[x] \subseteq X$ is open, iff the one-point set $\{ [x] \} \subseteq X/\sim$ is open:

$$[x] \subseteq X \text{ open} \iff \{ [x] \} \subseteq X/\sim \text{ open}$$

Nota A subset $P \subseteq X$ is said to be *saturated*, iff it is the union of some equivalence classes, i.e. iff $P = \bigcup \{ [p] \mid p \in P \}$. In this case we get $\varrho^{-1}(\varrho(P)) = P$. Therefore: If any open set $U \subseteq X$ already is saturated, then ϱ is an open map.

Connected Components

The aim of general topology is to generalize the concept of "nearby" in spaces in which there is no metric available. The concept if being "connected" is quintessential for this: Intuitively speaking a connected set is "all in one piece," without any separations or gaps. This is the formally correct way to speak of cohesion within a space and we will see that the propositions we derive match this intuition.

(6.32) Definition:

Let $(X, \mathcal{T})$ be any topological space and consider the subsets $X_i \subseteq X$ (where $i \in 1 \ldots n$) in the induced topology. Then X is said to be the **topological sum** of the X_i (which we denote by $X = X_1 \oplus \cdots \oplus X_n$) iff the X_i partition X and a subset $U \subseteq X$ is open if and only if any $U \cap X_i \subseteq X_i$ is open. Formally that is the X_i satisfy the following three properties

(1) $X = X_1 \cup \cdots \cup X_n$

(2) $\forall\, i \neq j \in 1 \ldots n \; : \; X_i \cap X_j = \emptyset$

(3) $\forall\, U \subseteq X$ we get $U \subseteq X$ open $\iff \big(\forall\, i \in 1 \ldots n : U \cap X_i \subseteq X_i \text{ open} \big)$

(6.33) Proposition: (viz. 1199)

(i) Suppose the topological space $(X, \mathcal{T})$ can be written as the topological sum $X = X_1 \oplus \cdots \oplus X_n$ for some subsets $X_i \subseteq X$. Then the X_i are both, open *and* closed subsets of X.

(ii) Let $(X, \mathcal{T})$ be any topological space and consider some subsets A, $B \subseteq X$, then we obtain the equivalence of the following statements

(a) $X = A \oplus B$

(b) $X = A \cup B$ and $\overline{A} \cap B = \emptyset = A \cap \overline{B}$

(c) A, $B \subseteq X$ are open and closed, $A \cap B = \emptyset$ and $A \cup B = X$

(iii) Consider some topological space $(X, \mathcal{T})$ containing the sets A, X_1 and $X_2 \subseteq X$ and for $i \in \{ 1, 2 \}$ let $A_i := X_i \cap A$. If X is the topological sum $X = X_1 \oplus X_2$ then A also is the topological sum $A = A_1 \oplus A_2$. Formally this is the implication

$$X = X_1 \oplus X_2 \implies A = A_1 \oplus A_2$$

(iv) Let $(X, \mathcal{T}_X)$ and $(Y, \mathcal{T}_Y)$ be any two topological spaces and consider a continuous map $f : X \to Y$. Further let $Y_1, Y_2 \subseteq Y$ be any subsets and for $i \in \{1,2\}$ let us denote $X_i := f^{-1}(Y_i)$. If now Y is the topological sum $Y = Y_1 \oplus Y_2$ then X also is the topological sum $X = X_1 \oplus X_2$. Formally this is the implication

$$Y = Y_1 \oplus Y_2 \quad \Longrightarrow \quad X = X_1 \oplus X_2$$

(6.34) Definition: (viz. 1200)
Let $(X, \mathcal{T})$ be an arbitrary topological space, then X is said to be **connected**, iff it satisfies one of the following equivalent conditions (a) to (d). A subset $C \subseteq X$ is said **connected**, iff it is connected in the relative topology, i.e. iff $(C, \mathcal{T} \cap C)$ is a connected topological space.

(a) The only subsets of X that are both, open and closed, are the trivial ones: $\emptyset$ and X.

(b) X cannot be decomposed as a non-trivial topological sum. That is for any two subsets $X_1, X_2 \subseteq X$ we get the implication $X = X_1 \oplus X_2 \implies X_1 = X$ or $X_2 = X$.

(c) If X is the union of *separated* subsets A and $B \subseteq X$ (that is $X = A \cup B$ and $\overline{A} \cap B = \emptyset = A \cap \overline{B}$) then we already get $A = X$ or $B = X$.

(d) If $A \subseteq X$ is a subset of X such that $A \neq \emptyset$ and $A \neq X$, then A has non-empty border $\partial A \neq \emptyset$.

(6.35) Proposition: (viz. 1200)
Let $(X, \mathcal{T}_X)$ be an arbitrary topological space and consider any two connected subsets C and $D \subseteq X$. Then we obtain the following statements

(i) If $A, B \subseteq X$ are any two subsets, with $C \subseteq A \cup B$ and $\overline{A} \cap B \cap C = \emptyset = A \cap \overline{B} \cap C$, then we already get $C \subseteq A$ or $C \subseteq B$.

(ii) If C and $D \subseteq X$ are connected subsets, such that the intersection $C \cap D \neq \emptyset$ is nonempty, then the union $C \cup D \subseteq X$ is connected, too.

(iii) More generally let $\mathcal{C} \subseteq \{ C \subseteq X \mid C \text{ connected} \}$ be a non-empty collection of connected subsets of X, that have non-empty intersection. Then their union is connected again

$$\mathcal{C} \neq \emptyset \text{ and } \bigcap \mathcal{C} \neq \emptyset \quad \Longrightarrow \quad \bigcup \mathcal{C} \subseteq X \text{ connected}$$

(iv) Consider a connected subset $C \subseteq X$ and an arbitrary subset $A \subseteq X$. Then we obtain the following implication

$$C \subseteq A \subseteq \overline{C} \quad \Longrightarrow \quad A \text{ connected}$$

(v) If $(Y, \mathcal{T}_Y)$ is any other topological space, $f : X \to Y$ is a continuous map and $C \subseteq X$ is a connected set in X, then the image $f(C) \subseteq Y$ is connected, too.

(6.36) Definition: (viz. 1201)
Let $(X, \mathcal{T})$ be an arbitrary topological space, then we obtain an equivalence relation $\sim$ on X by defining

$$x \sim y \quad :\Longleftrightarrow \quad \exists\, C \subseteq X \text{ connected } : \{ x, y \} \subseteq C$$

for any x, $y \in X$. The equivalence classes under this relation are said to be the **connected components** of X. And for any $x \in X$ we denote the connected component containing x by

$$\text{CNC}(x) \;:=\; [x] \;=\; \bigcup \{\, C \mid C \subseteq X \text{ connected } x \in C \,\}$$

We denote the quotient set of X under $\sim$ (that is the set of all connected components of X) by $\text{CNC}(X)$

$$\text{CNC}(X) \;:=\; X \big/ _{\sim} \;=\; \{\, \text{CNC}(x) \mid x \in X \,\}$$

(6.37) Proposition: (viz. 1201)
Let $(X, \mathcal{T})$ be a non-empty topological space and consider an arbitrary subset $A \subseteq X$ and a connected subset $X \subseteq X$. Then we obtain the statements

(i) If $K \in \text{CNC}(X)$ is a connected component of X, then K already is a closed, connected subset of X.

(ii) The connected components of X are precisely the maximal connected subsets of X. That is $K \subseteq X$ is a connected component iff it is a connected subset of X, such that for any other connected subset $C \subseteq X$ we get $K \subseteq C \implies K = C$. Put formally, that is

$$\text{CNC}(X) \;=\; \{\, C \subseteq X \mid C \text{ connected} \,\}^*$$

(iii) If $C \subseteq X$ is a connected subset, then there is a connected component $K \in \text{CNC}(X)$ such that $C \subseteq K$. And if $C \neq \emptyset$, then this K even is uniquely determined, formally

$$C \neq \emptyset, \text{ connected} \quad \Longrightarrow \quad \exists!\, K \in \text{CNC}(X) \,:\, C \subseteq K$$

(iv) In particular if X only has finitely many connected components, say $\text{CNC}(X) = \{\, K_1, \ldots, K_n \,\}$ for some $n \in \mathbb{N}$, then the connected components decompose X into a topological sum

$$X \;=\; K_1 \oplus \cdots \oplus K_n$$

Topological Groups
This is a textbook on algebra, not on general topology, so let's get back to algebra. The link between algebra and topology are topological groups - that are groups that also carry a topology and the group operations respect the topology. The theory is quite powerful: It takes little effort to generate topological groups, that are very well-behaved.

(6.38) Definition:
Let $(G,\circ)$ be any group and $\mathcal{T}$ be a topology on G. Then the triple $(G,\mathcal{T},\circ)$ is said to be a **topological group** iff the inversion map $\iota : G \to G : x \mapsto x^{-1}$ and for any x, $y \in G$ the composition maps λ_x (from left) and μ_x (from right) are continuous, where

$$\begin{aligned} \lambda_x &: G \to G : y \mapsto xy \\ \mu_y &: G \to G : y \mapsto xy \end{aligned}$$

Nota It is clear, that ι is self-inverse $\iota^{-1} = \iota$ and that $\lambda_x^{-1} = \lambda_{x^{-1}}$ respectively $\mu_y^{-1} = \mu_{y^{-1}}$. Thus, if $(G,\mathcal{T},\circ)$ is a topological group, then all these maps ι and all the λ_x and μ_y are continuous and hence even homeomorphisms (as their inverses are continuous, too).

(6.39) Proposition: (viz. 1203)
Let $(G,\circ)$ be any group and $\mathcal{T}$ be a topology on G. For any x, $y \in G$ regard the maps $\lambda_x : y \mapsto xy$ and $\mu_y : x \mapsto xy$ respectively. Also we regard the group composition map $\circ : G \times G \to G : (x,y) \mapsto xy$ where $G \times G$ is taken in the box (= product) topology. Then we obtain the equivalence of the following five statements:

(a) for any x, $y \in G$ the maps λ_x and $\mu : y$ are continuous

(b) the composition map $\circ : G \times G \to G : (x,y) \mapsto xy$ is continuous

(c) for any x, $y \in G$ and $U \subseteq G$ open, xU and $Uy \subseteq G$ are open, too

(d) for any x, $y \in G$ and $C \subseteq G$ closed, xC and $Cy \subseteq G$ are closed, too

(e) If $W \subseteq G$ is an open set and x, $y \in G$ are any elements satisfying $xy \in W$, then there are open neighbourhoods $U \in \mathcal{T}(x)$ and $V \in \mathcal{T}(y)$ such that for any $u \in U$ and $v \in V$ we have $uv \in W$.

(6.40) Remark:
If $(G,\circ)$ be any group and $\mathcal{T}$ is a topology on G, then in the light of proposition (6.39) we find the following set-theoretic description of a topological group: $(G,\mathcal{T},\circ)$ is a topological group, if and only if for any closed set $C \subseteq G$ we get the following statements

(1) for any $x \in G$ the coset $xC \subseteq G$ is closed

(2) for any $y \in G$ the coset $Cy \subseteq G$ is closed

(3) the set $C^{-1} := \{ x^{-1} \mid x \in C \} \subseteq G$ is closed

(6.41) Lemma: (viz. 1204)
Let $(G,+)$ be any commutative group and $(F_n) \subseteq \mathcal{P}(G)$ a sequence of subsets of G, that satisfy the following four properties (1) $F_0 = G$, (2) for any $n \in \mathbb{N}$ the set $F_n \leq_{\mathrm{g}} G$ is a subgroup, (3) for any $n \in \mathbb{N}$ we have the inclusion $F_{n+1} \subseteq F_n$ and (4) the intersection of all F_n is 0

$$\bigcap_{n\in\mathbb{N}} F_n = \{0\}$$

Then we obtain a metric d on G by letting $d(x,y) := 0$ for $x = y$ and for any $x, y \in G$ with $x \neq y$ we let

$$d(x,y) \;:=\; \frac{1}{2^n} \quad \text{where} \quad n \;:=\; \max\{\, k \in \mathbb{N} \mid x - y \in F_k \,\}$$

Thereby $x + F_n = \{\, y \in G \mid d(x,y) \leq 2^{-n} \,\}$ for any $n \in \mathbb{N}$. And if $\mathcal{T}$ is the topology on G induced by this metric, then $(G, \mathcal{T}, +)$ is a topological group. Thereby, for a subset $U \subseteq G$ the following three statements are equivalent

(a) $U \subseteq G$ is open

(b) $\forall\, x \in U : \exists\, r > 0 : B_r(x) \subseteq U$

(c) $\forall\, x \in U : \exists\, n \in \mathbb{N} : x + F_n \subseteq U$

Nota actually the exact values 2^{-n} of the metric are irrelevant. You might as well choose $1/(n+1)$ or most anything else. Generally speaking you can take $d(x,y) = \delta(n)$ for some function $\delta : \mathbb{N} \to \mathbb{R}$ that satisfies (1) $\delta(n) > 0$, (2) for any $n \in \mathbb{N}$ we have $\delta(n+1) < \delta(n)$ and (3) $(\delta(n)) \to 0$.

6.3 Banach Spaces

normed space sub-multiplicative norm
vector metrics $(x_n) \to x$ and $(y_n) \to y$ then $(ax_n) \to ax$ and $(x_n + y_n) \to x + y$ linear metrics $d(ax, ay) = |a|d(x, y)$ and $d(x, z) \leq d(x, y) + d(y, z)$ are vector metrics
infinite sums by the sequence of partial sums infinite sums over arbitrary index sets def: Cauchy-sequence, completeness, completion
Banach space Banach algebra
Let $(E, \|\cdot\|_E)$ and $(F, \|\cdot\|_F)$ be any two normed spaces over field $\mathbb{F} = \mathbb{R}$ of real or $\mathbb{F} = \mathbb{C}$ complex numbers. If $f : D \to F$ is any function over some open subset $D \subseteq E$ and $x \in D$ is a point therein, then f is said to be *differentiable* in x, iff there is some linear map $L : E \to F$ such that

$$\lim_{h \to 0} \frac{\|f(x+h) - L(h) - f(x)\|_F}{\|h\|_E} \;=\; 0$$

Thereby (due to the triangle inequality) the map L is uniquely determined and called the *derivative* of f in x, written as: $df(x) := L$. If now $\mathcal{D}(x, F)$ denotes the set of all functions $f : D \to F$ that are differentiable in x, then we find that $\mathcal{D}(x, F)$ is a subspace of $\mathcal{F}(D, F)$ and that the derivation $f \mapsto df(x)$ is an $\mathbb{F}$-linear map as well:

$$\mathcal{D}(x, F) \to \mathcal{L}(E, F) \;:\; f \mapsto df(x)$$

Completion of Metric Spaces

(6.42) Definition:
Let (X, d) be a metric space, then a sequence $(x_n) \subseteq X$ is said to be a **Cauchy-sequence** if its elements come ever closer. Formally iff it satisfies the following property

$$\forall\, \varepsilon > 0\ \exists\, n(\varepsilon) \in \mathbb{N}\ \forall\, m, n \geq n(\varepsilon) \quad : \quad d\big(x_m, x_n\big) < \varepsilon$$

Let us denote the set of all these Cauchy-sequences by $\text{Cauchy}\,(X, d)$ and the set of all convergent series by $\text{Conv}\,(X, d)$. Recall that (x_n) is **convergent** iff there is some $x \in X$, such that

$$\forall\, \varepsilon > 0\ \exists\, n(\varepsilon) \in \mathbb{N}\ \forall\, n \geq n(\varepsilon) \quad : \quad d\big(x_n, x\big) < \varepsilon$$

In symbols we write $(x_n) \to x$ for this property. Generally any convergent sequence also is a Cauchy-sequence, that is we always have $\text{Conv}\,(X, d) \subseteq \text{Cauchy}\,(X, d)$. And we say that (X, d) is a **complete** metric space, iff the converse is true as well, that is iff we have

$$\text{Conv}\,(X, d) \;=\; \text{Cauchy}\,(X, d)$$

Prob We need to verify $\text{Conv}\,(X, d) \subseteq \text{Cauchy}\,(X, d)$: Suppose we have $(x_n) \to x$, then given any $\varepsilon > 0$ we can choose some $n(\varepsilon) \in \mathbb{N}$ such that for any $n \geq n(\varepsilon)$ we get $d(x_n, x) < \varepsilon/2$. Thus for m, $n \geq n(\varepsilon)$ we get $d(x_m, x_n) \leq d(x_m, x) + d(x, x_n) < \varepsilon/2 + \varepsilon/2 = \varepsilon$, which is just what we needed.

(6.43) Lemma: (viz. 1205)
Completion of metric spaces: Let (X, d) be a metric space and let $\text{Cauchy}\,(X, d)$ denote the set of

Cauchy-sequences on X. Then we obtain an equivalence relation on $\text{Cauchy}(X,d)$, by defining

$$(x_n) \sim (y_n) \quad :\Longleftrightarrow \quad \forall\, \varepsilon > 0\ \exists\, n(\varepsilon) \in \mathbb{N}\ \forall\, n \geq n(\varepsilon) \quad : \ d(x_n, y_n) \ < \ \varepsilon$$

The equivalence class of $(x_n) \in \text{Cauchy}(X,d)$ is written as $[x_n] := \{\, (y_n) \in \text{Cauchy}(X,d) \mid (x_n) \sim (y_n) \,\}$ and the quotient space of $\text{Cauchy}(X,d)$ under this relation is called the **completion** of (X,d)

$$\widehat{X} \ := \ \text{Cauchy}(X,d) \Big/ \sim$$

For any $x \in X$ the constant sequence $(x) \subseteq X$ is convergent and hence a Cauchy-sequence. This yields a canonical, injective map from X into its completion

$$\kappa : X \hookrightarrow \widehat{X} \ : \ x \mapsto [x]$$

Due to this construction all the sequences $(d(x_n, y_n)) \subseteq \mathbb{R}$ converge for any Cauchy-sequences (x_n), $(y_n) \in \text{Cauchy}(X,d)$. And thereby we also obtain a well-defined, metric $\widehat{d}$ on $\widehat{X}$ by letting

$$\widehat{d}\big([x_n],[y_n]\big) \ := \ \lim_{n\to\infty} d(x_n, y_n)$$

For any x, $y \in X$ we thereby get $\widehat{d}([x],[y]) = d(x,y)$ such that the canonical map $\kappa : X \hookrightarrow \widehat{X}$ also is continuous. And the image of κ is dense in $\widehat{X}$. That is: If we regard X as a subset of $\widehat{X}$ under this embedding, then its closure is the entire space $\widehat{X}$

$$\overline{\kappa(X)} \ = \ \widehat{X}$$

Most importantly: The completion $(\widehat{X}, \widehat{d})$ of (X,d) not only extends X canonically, but also is a complete metric space. That is every Cauchy-sequence of $(\widehat{X}, \widehat{d})$ already converges to some point in $\widehat{X}$.

required: $\mathbb{R}$ is hausdorff and complete required: $x_n \leq y_n \implies x \leq y$ and also if $x_n \leq a$ (for any $n \geq N$) then $x \leq a$ required: $(x_n \pm y_n) \to x \pm y$ and $(x_n \cdot y_n) \to xy$ and if we scratch $y_n = 0$ from (y_n) then also $(x_n / y_n) \to x/y$ metric groups and rings completion of metric groups and rings

6.4 Hilbert Spaces

inner product = special case of sesqui-linear form

6.5 Operatoralgebras

Chapter 7

Polynomial Rings

Polynomials are a powerful tool in algebra, as they simulate all the algebraic operations (finite additions, multiplications and powers) that are native to algebras. In this setting polynomials are the generic example of R-algebras and we will find some very powerful statements (like the lemma of Gauss or noetherian normalisation) of general importance by studying polynomials. On the other hand polynomial rings are very tame, as by definition the variables are independent of one and another. Therefore polynomials are the perfect stepping stone on the way to general algebras.

Also polynomials have been one of the origins of modern algebra. While the solution formula for quadratic equations is ancient, the formulas for cubic and quartic equations defied discovery until the 16. century by Cardano, resp. his student Ferrari and others. Interest grew (literally) as there was a lot of money to be made, by computing the best rates of interest for italian bankiers and traders. But mathematicians kept their insights a secret, at that time, for competetive reasons. So in fact these formulas were discovered independently by several mathematicians - apparently the time was just about right for these discoveries. Although the formulas for solving equations of degree 3 and 4 have been found in short sequel, equations of degree 5 remained unsolved. It took another 200 years until, the reason for this had been unearthed: In the 18. century Abel was able to prove, that there *is* no general formula to solve equations of degree 5 or higher - quite interesting, he had found general limits to what mathematics can do (much like Gödel's incompleteness theorem). This will be a major spin-off of Galois theory, which combines group theory with field extensions.

However we will not pursue the theory of solving polynomial equations right now, but rather chose a top-down approach: We start with the general concept of group rings $R[t \mid A]$ and only later specialize to $A = \mathbb{N}^n$ which yields the polynomial ring $R[t_1, \ldots, t_n]$ in n variables. And only after that we come full circle to study the special properties polynomial ring $R[t]$ in one variable. We will encounter group rings again, when we tackle representation theory.

For now we aim at the general theory: If we order the monomials in a reasonable way, we will be able to introduce Gröbner-bases (of ideals of polynomials) which provide powerful computational algorithms, such as Buchberger's algorithm, that determines whether a polynomial is contained in a certain ideal, or not. This is a powerful generalization of division with remainder of polynomials in one variable.

7.1 Monomial Orders

We have already introduced the polynomial ring $R[t]$ in one variable (over a commutative ring R) as an example in section 1.4. And we have also used this concept several times before (e.g. for the characteristic polynomial of a linear mapping). In this chapter we will now introduce a powerful generalization of this ring - the polynomial ring (also called group ring) $R[t \mid A]$. Thereby R is a commutative ring once more and A will be any commutative monoid. On the other hand polynomial rings are natural examples of graded algebras. So it may be advantageous to first study graded algebras as a general concept. This will be done in the subsequent section.
There are a multitude of special cases of this concept which we will regard in this chapter, as well. The most important special case will be the polynomial ring $R[t_1, \ldots, t_n]$ in (finitely many) variables. The polynomials $f \in R[t_1, \ldots, t_n]$ are the working horses of ring theory, as they describe all the compositions (addition, multiplication and powers) that can be performed in a ring. This makes the study of the polynomial ring a task of vast importance and likewise gives the theory its punch.
The polynomial ring $R[t]$ is included into this general theory as the polynomial ring $R[t \mid A]$ where A is chosen to be the the natural numbers $A = \mathbb{N}$. Yet the algabraic structure of $\mathbb{N}$ is not the sole important property for $R[t]$. The natural order $\leq$ on $\mathbb{N}$ is of no lesser importance. Therefore we will first study moniods A that carry an adequate order, as well.
So first recall the definition of a *linear order* (also called *total order*). If you are not familiar with this notion take a look at the introduction (section 0.3) or (re)read the beginning of section 2.1 for even more comments. So let us now introduce the basic concepts of ordered monoids:

(7.1) Definition:
Let $(A, +)$ be a commutative monoid and denote its neutral element by 0. Then we introduce the following notions: A is said to be **integral** iff for any α, β and $\gamma \in A$ we get the implication

$$\alpha + \gamma \;=\; \beta + \gamma \quad \Longrightarrow \quad \alpha \;=\; \beta$$

[in particular any commutative group A is an integral monoid]. Further A is said to be **solution-finite** iff for any fixed $\gamma \in A$ the equation $\alpha + \beta = \gamma$ has finitely many solutions only, formally that is

$$\forall\, \gamma \in A \;\; : \;\; \#\left\{\, (\alpha, \beta) \in A^2 \mid \alpha + \beta = \gamma \,\right\} \;<\; \infty$$

(7.2) Proposition: (viz. 1208)
If $(A, +)$ and $(B, +)$ are two commutative monoids, then their product $A \times B$ is another commutative monoid under the point-wise addition

$$(\alpha, \beta) + (\gamma, \delta) \;\; := \;\; (\alpha + \gamma,\, \beta + \delta)$$

The neutral element of $A \times B$ is $0 = (0_A, 0_B)$. And if both A and B are integral, resp. solution-finite then $A \times B$ is integral resp. solution finite again.

(7.3) Definition:

(i) The triple $(A, +, \leq)$ is said to be a **positively ordered monoid**, iff A is a commutative monoid under the addition $+$ and $\leq$ is a total, *positive* order on A. Formally we require the properties

(1) $(A, +)$ is a commutative monoid (with neutral element 0)

(2) $\leq$ is a linear order on A such that for any elements α, α' and $\beta \in A$ we get the implication

$$\alpha \leq \alpha' \quad \Longrightarrow \quad \alpha + \beta \leq \alpha' + \beta$$

(ii) The triple $(A, +, \leq)$ is said to be a **strictly positively ordered monoid**, iff A is commutative monoid under the addition $+$ and $\leq$ is a total, *strictly positive* order on A. Formally again we require

(1) $(A, +)$ is a commutative monoid (with neutral element 0)

(2) $\leq$ is a linear order on A such that for any elements α, α' and $\beta \in A$ we get the implication

$$\alpha < \alpha' \quad \Longrightarrow \quad \alpha + \beta < \alpha' + \beta$$

Nota that we used the notation $a < b \ :\Longleftrightarrow \ a \leq b$ and $a \neq b$ here. Also it is clear that a strictly positively ordered monoid already is a positively ordered monoid, as $\alpha = \alpha'$ implies $\alpha + \beta = \alpha' + \beta$ in any case.

(iii) Finally $(A, +, \leq)$ is said to be a **well-ordered monoid** and $\leq$ is said to be a **monomial well-ordering** on $(A, +)$ iff A is commutative monoid under the addition $+$ and $\leq$ is a *well-ordering* on A. Formally we require the following properties

(1) $(A, +, \leq)$ is a positively ordered monoid (with neutral element 0)

(2) $\leq$ is a *well-ordering* on A, that is a total order, such that any non-empty subset M of A has a minimal element. Formally the latter can be written as

$$\forall \emptyset \neq M \subseteq A \ \exists \mu_* \in M \quad \text{such that} \quad \forall \mu \in M \text{ we get } \mu_* \leq \mu$$

(7.4) Remark:
If now $(A, +, \leq)$ is a positively ordered monoid, we extend A to $\overline{A}$ by formally picking up a new element (that we introduce a new symbol $-\infty$ to A) $\overline{A} := A \cup \{ -\infty \}$. We then extend the composition $+$ and the order $\leq$ of A to $\overline{A}$ by defining the following operations and relations for any $\alpha \in A$

$$\begin{aligned} (-\infty) &\neq \alpha \\ (-\infty) &\leq \alpha \\ (-\infty) + \alpha &:= -\infty \\ \alpha + (-\infty) &:= -\infty \end{aligned}$$

Nota clearly $(\overline{A}, +)$ is a commutative monoid again and if $\leq$ has been a positive order or even a monomial well-ordering on A then the extended order on $\overline{A}$ is a positive order resp. a monomial well-ordering again.

(7.5) Example:
The standard example of a monoid that we will use later is $\mathbb{N}^n$ under the point-wise addition as the composition. However we will already discuss a slight generalization of this monoid here. Let $I \neq \emptyset$ be any non-empty index set and let us define the set

$$\mathbb{N}^{\oplus I} \quad := \quad \Big\{ \alpha \in \mathbb{N}^I \mid \#\{ i \in I \mid \alpha_i \neq 0 \} < \infty \Big\}$$

If I is finite, say $I = 1 \dots n$, then it is clear, that $\mathbb{N}^{\oplus(1\dots n)} = \mathbb{N}^n$. We now turn this set into a commutative monoid by defining the composition $+$ to be the point-wise addition, i.e. for any $\alpha = (\alpha_i)$ and $\beta = (\beta_i)$

$$(\alpha_i) + (\beta_i) \quad := \quad (\alpha_i + \beta_i)$$

And it is clear that this composition turns $\mathbb{N}^{\oplus I}$ into a commutative monoid, that is integral and solution-finite (for any $\gamma \in \mathbb{N}^{\oplus I}$ the set of solutions (α, β) of $\alpha + \beta = \gamma$ is given to be $\{ (\alpha, \gamma - \alpha) \mid \alpha_i \leq \gamma_i \}$, which is finite, as $\gamma_i = 0$ for all but finitely many $i \in I$). For any $i \in I$ we now define

$$\delta_i \ : \ I \to \mathbb{N} \ : \ j \mapsto \delta_{i,j}$$

where $\delta_{i,j}$ denotes the Kronecker symbol (e.g. refer to the notation and symbol list). From the construction it is clear, that any $\alpha = (\alpha_i) \in \mathbb{N}^{\oplus I}$ is a (uniquely determined) *finite* sum of these δ_i since

$$(\alpha_i) \quad = \quad \sum_{i \in I} \alpha_i \, \delta_i$$

This sum in truth is finite as only finitely many coefficients α_i are non-zero and we can omit those $i \in I$ with $\alpha_i = 0$ from the sum. This enables us to introduce some notation here that will be put to good use:

- Let us first define the **absolute value** of $\alpha = (\alpha_i) \in \mathbb{N}^{\oplus I}$ to be the sum of its entries [this is the 1-norm of α] and the **norm** of α to be the maximum entry of α [this is the ∞-norm of α]:

$$\begin{aligned} |\alpha| \quad &:= \quad \sum_{i \in I} \alpha_i \\ \|\alpha\| \quad &:= \quad \max\{ \alpha_i \mid i \in I \} \end{aligned}$$

- For a fixed weight $\omega \in \mathbb{N}^I$ we introduce the **weighted sum** of α (note that this is well-defined, as $\alpha \in \mathbb{N}^{\oplus I}$ only has finitely many non-zero entries and hence the sum is finite only)

$$|\alpha|_\omega \quad := \quad \sum_{i \in I} \omega_i \, \alpha_i$$

- Another often useful notation (for any $\alpha \in \mathbb{N}^{\oplus I}$ and any $k \in \mathbb{N}$ with $\|\alpha\| \leq k$) are the **faculty** and **binomial coefficients**, which are defined to be

$$\begin{aligned} \alpha! \quad &:= \quad \prod_{i \in I} \alpha_i! \\ \binom{k}{\alpha} \quad &:= \quad \prod_{i \in I} \binom{k}{\alpha_i} \end{aligned}$$

- And if $x = (x_i) \in R^I$ is an I-tupel of elements of a commutative ring $(R, +, \cdot)$ we finally introduce the notations (note that these are well-defined again, as $\alpha \in \mathbb{N}^{\oplus I}$ has only finitely many $\alpha_i \neq 0$)

$$\begin{aligned} \alpha x &:= \sum_{i \in I} \alpha_i \, x_i \\ x^\alpha &:= \prod_{i \in I} x_i^{\alpha_i} \end{aligned}$$

(7.6) Proposition: (viz. 1208)

(i) Let A be any set and $\leq \subseteq A \times A$ be a linear order on A. Then any finite, non-empty subset $M \subseteq A$ has uniquely determined minimal and a maximal elements. I.e. for any $M \subseteq A$ with $1 \leq \#M < \infty$ we get

$$\begin{aligned} \exists!\, \mu_* \in M \,:\, \forall\, \mu \in M \;&:\; \mu_* \leq \mu \\ \exists!\, \mu^* \in M \,:\, \forall\, \mu \in M \;&:\; \mu \leq \mu^* \end{aligned}$$

Nota we will refer to these uniquely determined minimal and maximal elements of M by writing $\min(M) := \mu_*$ and $\max(M) := \mu^*$ respectively.

(ii) Let A be any set and $\leq \subseteq A \times A$ be a well-ordering on A. Then any non-empty subset $M \subseteq A$ has a uniquely determined minimal element. I.e. for any $M \subseteq A$ with $M \neq \emptyset$ we get

$$\exists!\, \mu_* \in M \,:\, \forall\, \mu \in M : \mu_* \leq \mu$$

(iii) Let $(A, +)$ be a commutative monoid and let $\leq \subseteq A \times A$ be a linear order on A. Then the following three statements are equivalent

(a) A is integral and $\leq$ is a positive order on A

(b) $(A, +, \leq)$ is a strictly positively ordered monoid

(c) for any $\alpha, \beta, \gamma \in A$ we get $\alpha < \beta \iff \alpha + \gamma < \beta + \gamma$

(iv) Let $(A, +, \leq)$ be a strictly positively ordered monoid. Let further M, $N \subseteq A$ be any two subsets and $\mu_* \in M$ respectively $\nu_* \in N$ be minimal elements of M and N, that is we have

$$\forall\, \mu \in M \,:\, \mu_* \leq \mu \quad \text{and} \quad \forall\, \nu \in N \,:\, \nu_* \leq \nu$$

Then for any elements $\mu \in M$ and $\nu \in N$ we get: If $\mu + \nu$ equals the sum $\mu_* + \nu_*$ of minimal elements then necessarily $\mu = \mu_*$ and $\nu = \nu_*$ are these minimal elements already, formally

$$\mu + \nu \,=\, \mu_* + \nu_* \quad \Longrightarrow \quad \mu \,=\, \mu_* \;\text{ and }\; \nu \,=\, \nu_*$$

Nota the same is true for maximal elements $\mu^* \in M$ and $\nu^* \in N$. That is if $\mu \leq \mu^*$ and $\nu \leq \nu^*$ for any $\mu \in M$ and $\nu \in N$ respectively, then $\mu + \nu = \mu^* + \nu^*$ implies $\mu = \mu^*$ and $\nu = \nu^*$, as well.

(vii) If $(A, +, \leq)$ is a (strictly) positively ordered monoid, then we define the *inverse order* $\geq$ by letting: $\alpha \geq \beta \;:\Longleftrightarrow\; \beta \leq \alpha$. And thereby $(A, +, \geq)$ is a (strictly) positively ordered monoid, again.

(viii) If $(A,+,\leq)$ is an integral, positively ordered monoid such that for any $\gamma \in A$ the set $\{\, \alpha \in A \mid \alpha \leq \gamma \,\}$ is finite, then A is solution-finite, as well.

(ix) If $(A,+,\leq)$ is an integral, positively ordered monoid, that also is solution-finite, then $(0,0)$ is the one and only solution for $\alpha+\beta=0$. That is for any α, $\beta \in A$ we get the implication

$$\alpha+\beta \;=\; 0 \quad\Longrightarrow\quad \alpha \;=\; 0 \;=\; \beta$$

(7.7) Example: (viz. 1210)
Let now $(I,\leq)$ be a well-ordered set (i.e. $I \neq \emptyset$ is a non-empty set and $\leq$ is a well-ordering on I) and fix any weight $\omega \in \mathbb{N}^I$. Then we introduce two different linear orders on the commutative monoid $(\mathbb{N}^{\oplus I},+)$. Of these the ω-graded lexicographic order will be the standard order we will employ in later sections. Thus consider $\alpha=(\alpha_i)$ and $\beta=(\beta_i) \in \mathbb{N}^{\oplus I}$ and define

- **Lexicographic Order**

$$\alpha \leq_{\text{lex}} \beta \quad :\Longleftrightarrow \quad (\alpha=\beta) \text{ or } (*)$$

$$(*) \;:=\; \exists k \in I \text{ such that } \alpha_k < \beta_k \text{ and } \forall\, i<k \,:\, \alpha_i=\beta_i$$

 Then the lexicographic order $\leq_{\text{lex}}$ is strictly positive, i.e. the triple $(\mathbb{N}^{\oplus I},+,\leq_{\text{lex}})$ is a strictly positively ordered monoid. And in case of $I=1\ldots n$ is finite, we will see that $\leq_{\text{lex}}$ even is a well-ordering, i.e. the triple $(\mathbb{N}^n,+,\leq_{\text{lex}})$ is a well-ordered monoid, too.

- **ω-Graded Lexicographic Order**

$$\alpha \leq_\omega \beta \quad :\Longleftrightarrow \quad (|\alpha|_\omega < |\beta|_\omega) \text{ or } (|\alpha|_\omega = |\beta|_\omega \text{ and } \alpha \leq_{\text{lex}} \beta)$$

 Analogously the ω-graded lexicographic order $\leq_\omega$ is strictly positive, i.e. $(\mathbb{N}^{\oplus I},+,\leq_\omega)$ is a strictly positively ordered monoid. And in the case $I=1\ldots n$ is finite it even is a well-ordering, i.e. the triple $(\mathbb{N}^n,+,\leq_\omega)$ is a well-ordered monoid once more.

(7.8) Remark:
For an arbitrary, non-empty set $I \neq \emptyset$ the *well-ordering theorem* says, that there *is* some linear well-ordering $\leq$ on I. Even though we can't put it explicitly, there is some. However the theorem does not not guarantee that this ordering is compatible with addition, i.e. whether A will be turned into a positively ordered monoid. However this is not what we aim for:
We already know, that $(\mathbb{N}^{\oplus I},+)$ is a commutative, integral monoid. Now the example above also tells us that$(\mathbb{N}^{\oplus I},+,\leq_{\text{lex}})$ even is a strictly positively ordered monoid. And if I is finite, then we even have the well-ordering property. The lexicographic order is nice to have, since $\mathbb{N}^n$ will be the standard monoid for polynomial rings. We will not pursue the general theory any further, as this suffices for Gröbner-bases.

(7.9) Remark: (■)
We wish to append two further linear orders on $(\mathbb{N}^{\oplus I}, +)$. However we will not require these any further and hence abstain from proving any details about them. The interested reader is asked to refer to [Cox, Little, O'Shaea; Using Algebraic Geometry, GTM 185] for more comments on these.

- **Reverse Graded Lexicographic Order**

$$\alpha \leq_{\text{rgl}} \beta \quad :\Longleftrightarrow \quad (\alpha = \beta) \text{ or } (|\alpha| < |\beta|) \text{ or } (|\alpha| = |\beta| \text{ and } (2))$$

$$(2) \quad := \quad \exists k \in I \text{ such that } \alpha_k > \beta_k \text{ and } \forall i < k \,:\, \alpha_i = \beta_i$$

 Just like $\leq_\omega$ the reverse graded lexicographic order $\leq_{\text{rgl}}$ is positive and in the case of $I = 1 \dots n$ it even is a well-ordering again.

- **Bayer-Stillman Order**
 For the fourth order we will require $I = 1 \dots n$ already. Then we fix any $m \in 1 \dots n$ and obtain another monomial well-ordering on $\mathbb{N}^n$

$$\alpha \leq_{\text{bs}(m)} \beta \quad :\Longleftrightarrow \quad (3) \text{ or } ((4) \text{ and } \alpha \leq_{\text{rgl}} \beta)$$

$$(3) \quad := \quad \alpha_1 + \dots + \alpha_m < \beta_1 + \dots + \beta_m$$

$$(4) \quad := \quad \alpha_1 + \dots + \alpha_m = \beta_1 + \dots + \beta_m$$

7.2 Defining Polynomials

Polynomials are of tremendous importance in ring-theory, since they embody all the operations of rings and fields. We already introduced the polynomial ring in one variable as an example, but now we wish to turn to the general setting. In this section we only require the notions of section 7.1 and not the graded algebras of section 7.4 yet. Later on, in section 7.3 we will specify this general setting to the cases that are used most often, the polynomial rings $R[t_1, \ldots, t_n]$ at their center.

(7.10) Definition:
Let $(R, +, \cdot)$ be a commutative ring (denoting its neutral elements by 0 and 1 as usual) and let $(A, +)$ be a monoid (denoting its neutral element by 0, too), then we introduce the following notions

(i) We define the set of **formal A-series** over R to be all the functions from A to R and denote it by

$$R[\![t \mid A]\!] \;:=\; \{\, f \mid f : A \to R : \alpha \mapsto f[\alpha] \,\}$$

Note that in order to get an unambiguous notation we have already abandoned our standard notation and wrote $f[\alpha] := f(\alpha) \in R$ instead. Also please be aware that the use of the variable symbol t in $R[\![t \mid A]\!]$ is purely notational and will be explained in the subsequent remark.

We now turn $R[\![t \mid A]\!]$ into an R-module by defining the following addition and scalar-multiplication

$$f + g \;:\; A \to R \;:\; \alpha \mapsto f[\alpha] + g[\alpha]$$

$$a f \;:\; A \to R \;:\; \alpha \mapsto a \cdot f[\alpha]$$

If A is solution-finite the formal A-series $R[\![t \mid A]\!]$ even becomes an R-algebra under the following multiplication - where $f, g \in R[\![t \mid A]\!]$ and $a \in R$ of course and $\sum_{\alpha+\beta=\gamma}$ denotes the (finite) sum over the set $\{\, (\alpha, \beta) \in A^2 \mid \alpha + \beta = \gamma \,\}$ of all pairs (α, β) that satisfy $\alpha + \beta = \gamma$

$$f \cdot g \;:\; A \to R \;:\; \gamma \mapsto \sum_{\alpha+\beta=\gamma} f[\alpha] \cdot g[\beta]$$

(ii) We define the set of **A-polynomials** over R to be the functions from A to R that are non-zero on finitely many elements $\alpha \in A$ only

$$R[t \mid A] \quad:=\quad \{\, f : A \to R \mid \;\; \#\{\, \alpha \in A \mid f[\alpha] \neq 0 \,\} < \infty \,\}$$

Nota it is clear that the polynomials $R[t \mid A]$ thereby become an R-sub-module of the formal A-series $R[\![t \mid A]\!]$. And $R[t \mid A]$ even is an R-algebra under the above multiplication, even if A is not solution-finite, as the products $f[\alpha] \cdot g[\beta]$ are zero for all but finitely many $(\alpha, \beta) \in A^2$, such that the sum $\sum_{\alpha+\beta=\gamma}$ remains finite, even if $\{\, \alpha + \beta = \gamma \,\}$ is infinite.

(7.11) Remark:

(i) From the definition of the polynomial ring $R[t \mid A]$ is clear, that this is a free R-module of rank $|A|$ as an R-basis of $R[t \mid A]$ is given by $\{ t^\alpha \mid \alpha \in A \}$, where the **monomial** t^α is defined to be the following A-polynomial

$$t^\alpha \;:\; A \to R \;:\; \beta \mapsto \begin{cases} 0 & \text{for } \alpha \neq \beta \\ 1 & \text{for } \alpha = \beta \end{cases}$$

And thereby the monomials satisfy the following important multiplicative property for any $\alpha, \beta \in A$

$$t^\alpha \, t^\beta \quad = \quad t^{\alpha+\beta}$$

Prob consider any $\gamma \in A$, then $(t^\alpha \, t^\beta)[\gamma] = \sum_{\alpha'+\beta'=\gamma} \delta_{\alpha',\alpha}\delta_{\beta',\beta}$ and the product $\delta_{\alpha',\alpha}\delta_{\beta',\beta}$ yields 1 if and only if $\alpha' = \alpha$ and $\beta' = \beta$. Hence if $\gamma = \alpha + \beta$ then we get $(t^\alpha \, t^\beta)[\gamma] = 1$ for this one combination. And if $\gamma \neq \alpha + \beta$ then the combination $\alpha' = \alpha$ and $\beta' = \beta$ does not occur, such that $(t^\alpha \, t^\beta)[\gamma] = 0$. But this is precisely, what $t^{\alpha+\beta}$ does and hence $t^\alpha \, t^\beta = t^{\alpha+\beta}$ as claimed.

(ii) We will use this standard basis most often and the variable symbol t in $R[t \mid A]$ denotes just what symbols t^α we will use for the monomials. Now any polynomial $f \in R[t \mid A]$ has a unique representation in this standard basis, given by

$$f \quad = \quad \sum_{\alpha \in A} f[\alpha] \, t^\alpha$$

Note that this sum in truth is finite only, as (by construction) the coefficients $f[\alpha]$ are zero for all but finitely many $\alpha \in A$.

(iii) We will formally adopt this representation to $R[\![t \mid A]\!]$. Note however that this sum *can be* infinite and hence may well have absolutely no meaning apart from fixing the coefficients $f[\alpha]$ of the power series f. That is, we also write

$$\sum_{\alpha \in A} f[\alpha] \, t^\alpha \quad := \quad (A \to R \;:\; \alpha \mapsto f[\alpha])$$

(iv) This is precisely the reason why we defined the multiplication of formal power series and polynomials, in the way we did: This multiplication neatly incorporates the general rule distributivity. Combined with the notation in (iii) the multiplication of formal power series (if A is solution-finite) and polynomials (in general) f and g yields

$$\left(\sum_{\alpha \in A} f[\alpha] t^\alpha \right) \cdot \left(\sum_{\beta \in A} g[\beta] t^\beta \right) \quad = \quad \sum_{\gamma \in A} \left(\sum_{\alpha+\beta=\gamma} f[\alpha] \, g[\beta] \right) t^\gamma$$

(7.12) Proposition: (viz. 791)
Let $(R,+,\cdot)$ be a commutative ring and $(A,+)$ be a monoid, then all of the following statements are true

(i) The unit element $\mathbf{1}$ of the polynomial ring $R[t \mid A]$ is given by

$$\mathbf{1} \;=\; t^0 \;:\; A \to R \;:\; \alpha \mapsto \begin{cases} 1 & \text{if} \quad \alpha = 0 \\ 0 & \text{if} \quad \alpha \neq 0 \end{cases}$$

(ii) R is embedded into all the polynomial rings over R. That is: We have an injective homomorphism of R-algebras by virtue of

$$\iota \;:\; R \hookrightarrow R[t \mid A] \;:\; a \mapsto a\,\mathbf{1}$$

In this sense R will always be interpreted as a sub-ring of $R[t \mid A]$, e.g. if $f \in R[t \mid A]$ is a polynomial we will write $f \in R$ to express that f is of the form $f = a\,\mathbf{1}$ for some R$a \in R$ and such a polynomial will be called a **constant** polynomial over R.

(iii) If $(B,+)$ is a commutative monoid, such that $A \leq_o B$ is a submonoid of B, then we find a canonical embedding of the polynomial rings

$$R[t \mid A] \hookrightarrow R[t \mid B] \;:\; f \mapsto \left(\beta \mapsto \begin{cases} f[\beta] & \text{if} \quad \beta \in A \\ 0 & \text{if} \quad \beta \notin A \end{cases}\right)$$

I.e. this map is a monomorphism of R-algebras. And if B is solution-finite then this embedding extends to the rings of formal power series

$$R[\![t \mid A]\!] \hookrightarrow R[\![t \mid B]\!] \;:\; f \mapsto \left(\beta \mapsto \begin{cases} f[\beta] & \text{if} \quad \beta \in A \\ 0 & \text{if} \quad \beta \notin A \end{cases}\right)$$

(iv) If $(S,+,\cdot)$ is another commutative ring and $\varphi : R \to S$ is a homomorphism of rings, then we obtain another homomorphism $\overline{\varphi}$ of R-modules

$$\overline{\varphi} \;:\; R[\![s \mid A]\!] \;\to\; S[\![t \mid A]\!] \;:\; \sum_{\alpha \in A} f[\alpha]\, t^\alpha \;\mapsto\; \sum_{\alpha \in A} \varphi(f[\alpha])\, t^\alpha$$

Clearly this homomorphism restricts to the polynomial ring and in fact it is a homomorphism of R-algebras there. Also $\overline{\varphi}$ is a homomorphism of R-algebras, in case A is solution-finite

$$\overline{\varphi} \;:\; R[s \mid A] \;\to\; S[t \mid A] \;:\; \sum_{\alpha \in A} f[\alpha]\, t^\alpha \;\mapsto\; \sum_{\alpha \in A} \varphi(f[\alpha])\, t^\alpha$$

Let us abbreviate any one of the words *injective*, *surjective* or *bijective* by $\star$, then we obtain the following property: If φ is $\star$, then $\overline{\varphi}$ is $\star$, as well.

(v) The polynomial ring $R[t \mid A]$ is commutative iff the monoid A is such. And if A is solution-finite the same is true for the formal A-series. That is we have the following two equivalences

$$\begin{aligned} R[t \mid A] \text{ is commutative} \quad &\Longleftrightarrow \quad A \text{ is commutative} \\ R[\![t \mid A]\!] \text{ is commutative} \quad &\Longleftrightarrow \quad A \text{ is commutative} \end{aligned}$$

(vi) Consider any two commutative monoids $(A,+)$ and $(B,+)$. Then the polynomial ring over B over the polynomial ring over A is isomorphic to the polynomial ring over $A \times B$. That is we have the isomorphy (of R-algebras)

$$\begin{array}{rcl} R[s \mid A][t \mid B] & \xrightarrow{\sim} & R[x \mid A \times B] \\ \displaystyle\sum_{\beta\in B}\left(\sum_{\alpha\in A} f[\beta][\alpha]\, s^{\alpha}\right) t^{\beta} & \mapsto & \displaystyle\sum_{(\alpha,\beta)\in A\times B} f[\beta][\alpha]\, x^{(\alpha,\beta)} \end{array}$$

And if both A and B are solution-finite, then the same isomorphism runs between the formal power series over B over A and over $A \times B$. Formally again

$$\begin{array}{rcl} R[\![s \mid A]\!][\![t \mid B]\!] & \xrightarrow{\sim} & R[\![x \mid A \times B]\!] \\ \displaystyle\sum_{\beta\in B}\left(\sum_{\alpha\in A} f[\beta][\alpha]\, s^{\alpha}\right) t^{\beta} & \mapsto & \displaystyle\sum_{(\alpha,\beta)\in A\times B} f[\beta][\alpha]\, x^{(\alpha,\beta)} \end{array}$$

(vii) Let $(A,+,\leq)$ be a positively ordered monoid such that $(A,+)$ even is integral and let $\star$ abbreviate one of the words *integral domain* or *reduced ring*. Then the following two statements are equivalent

(a) R is a $\star$

(b) $R[t \mid A]$ is a $\star$

And if R and hence $R[t \mid A]$ is an integral domain, we denote its quotient field by $R(t \mid A)$, which is called the field of *rational fractions* of R over A. Formally that is

$$R(t \mid A) \;:=\; \mathrm{QUOT}\big(R[t \mid A]\big)$$

(viii) Let $(A,+,\leq)$ be an positively ordered monoid such that $(A,+)$ even is integral and for any $\gamma \in A$ the set $\{\, \alpha \in A \mid \alpha \leq \gamma \,\}$ is finite. Again let $\star$ abbreviate one of the words *integral domain* or *reduced ring*. Then we also have the equivalence, of the following two statements

(a) R is a $\star$

(b) $R[\![t \mid A]\!]$ is a $\star$

And if R and hence $R[\![t \mid A]\!]$ is an integral domain, we denote its quotient field (which does have a special name, of its own) by

$$R((t \mid A)) \;:=\; \mathrm{QUOT}\big(R[\![t \mid A]\!]\big)$$

(7.13) Example:
Let $(R,+,\cdot)$ be a commutative ring, $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ an ideal of R and let $(A,+)$ be a monoid. We consider the residue ring $S := R/\mathfrak{a}$ and the canonical epimorphism $\varrho : R \to S : b \mapsto b + \mathfrak{a}$. Then the induced homomorphism $\overline{\varrho} : R[t \mid A] \to S[t \mid A]$ is surjective and has the kernel $\mathrm{kn}(\overline{\varrho}) = \mathfrak{a}[t \mid A]$ which is to say $\mathfrak{a}[t \mid A] := \{\, f \in R[t \mid A] \mid \forall\, \alpha \in A : f[\alpha] \in \mathfrak{a} \,\}$. In particular we obtain an isomorphy of R-algebras

$$R[t \mid A] \Big/ \mathfrak{a}[t \mid A] \;\xrightarrow{\sim}\; \Big(R \Big/ \mathfrak{a}\Big)\,[t \mid A] \;:\; f + \mathfrak{a}[t \mid A] \mapsto \sum_{\alpha\in A} \big(f[\alpha] + \mathfrak{a}\big)\, t^{\alpha}$$

Prob by (7.12.(iv)) $\overline{\varrho}$ is an epimorphism, too and $\overline{\varrho}(f) = 0$ is equivalent to $f[\alpha] \in \mathfrak{a}$ for any $\alpha \in A$. In other words this is $f \in \mathfrak{a}[t \mid A]$, so the isomorphy is granted by the first isomorphism theorem.

(7.14) Lemma: (viz. 794)
Let now $(R, +, \cdot)$ and $(S, +, \cdot)$ be commutative rings and $(A, +)$ be a commutative monoid. Further suppose that $\varphi : R \to S$ is a homomorphism of rings and $\sigma : A \to S$ is a homomorphism of monoids from $(A, +)$ to $(S, \cdot)$ (see the remark below, for the explicit properties, we require of σ)

$$\begin{aligned} \varphi &: R \to S \quad \text{is a ring-homomorphism and} \\ \sigma &: A \to S \quad \text{is a monoid-homomorphism} \end{aligned}$$

Together φ and σ induce a ring-homomorphism $\sigma_\varphi : R[t \mid A] \to S$ that also satifies $\sigma_\varphi(af) = \varphi(a) \cdot \sigma_\varphi(f)$ for any $a \in R$ and $f \in R[t \mid A]$. And this homomorphism is uniquely determined by the properties

- $\forall\ \lambda \in R$ we get $\sigma_\varphi(\lambda \mathbf{1}) = \varphi(\lambda)$
- $\forall\ \alpha \in A$ we get $\sigma_\varphi(t^\alpha) = \sigma(\alpha)$

(7.15) Remark:

- By the property that σ is a monoid-homomorphism we understand that $\sigma(0_A) = 1_S$ and that for any $\alpha, \beta \in A$ we get $\sigma(\alpha + \beta) = \sigma(\alpha) \cdot \sigma(\beta)$.
- Note that this ring-homomorphism σ_φ can be given explicitly: It simply is the R-linear expansion by $a \mapsto \varphi(a)$ of $t^\alpha \mapsto \sigma(\alpha)$, that is σ_φ is given to be

$$\sigma_\varphi\left(\sum_{\alpha \in A} a_\alpha\, t^\alpha\right) \quad = \quad \sum_{\alpha \in A} \varphi(a_\alpha)\, \sigma(\alpha)$$

- The standard situation is $A = \mathbb{N}^{\oplus I}$ and S an R-algebra of course. In this case we usually fix any I-tuple of elements $x = (x_i) \in R^I$ and take $\varphi : a \mapsto a1_S$ to be the *structural homomorphism* and σ to be the map $\sigma : \alpha \mapsto x^\alpha := \prod_i x_i^{\alpha(i)}$. Note that this product is well-defined, as $\alpha(i) = 0$ for all but finitely many $i \in I$. Refer to (7.52) for more comments on this. Then we get

$$f(x) \quad := \quad \sigma_{\mathbb{1}}(f) \quad = \quad \sum_{\alpha \in \mathbb{N}^{\oplus I}} f[\alpha]\, x^\alpha$$

(7.16) Remark: (viz. 795)
This proposition has an strange consequence: *Any* commutative ring $(R, +, \cdot)$ is the epimorphic image of an integral domain. That is there is an integral domain $(S, +, \cdot)$ and a surjective homomorphism ϱ of rings of the form

$$\varrho \ : \ S \ \twoheadrightarrow \ R$$

(7.17) Definition:
Let $(R,+,\cdot)$ be a commutative ring and $(A,+)$ be a commutative monoid. Further fix a total order $\leq$ on A then we define the following notions

(i) For a polynomial $f \in R[t \mid A]$ we define the **degree** $\deg(f) \in A \cup \{-\infty\}$ of f to be the maximal index $\alpha \in A$ such that $f[\alpha] \neq 0$. If there is none (i.e. $f = 0$), then we let $\deg(f) = -\infty$. Altogether

$$\deg(f) := \begin{cases} \max\{\alpha \in A \mid f[\alpha] \neq 0\} \text{ if } f \neq 0 \\ -\infty \text{ if } f = 0 \end{cases}$$

(ii) And thereby we define the **leading coefficient** $\operatorname{lc}(f) \in R$ of $f \in R[t \mid A]$ to be this non-zero coefficient $f[\alpha] \in R \setminus \{0\}$ of f, for which $\alpha = \deg(f)$ is maximal. If $f = 0$, we let $\operatorname{lc}(f) := 0 \in R$ instead. If $\operatorname{lc}(f) = 1 \in R$, then f is said to be **monic**. Altogether

$$\operatorname{lc}(f) := \begin{cases} f[\deg(f)] \text{ if } f \neq 0 \\ 0 \text{ if } f = 0 \end{cases}$$

(iii) Further we define the **leading monomial** $\operatorname{lm}(f) \in R[t \mid A]$ of $f \in R[t \mid A]$ to be this monomial t^α for which $\alpha = \deg(f)$ is maximal. If $f = 0$, we let $\operatorname{lm}(f) := 0 \in R[t \mid A]$ instead. Altogether

$$\operatorname{lm}(f) := \begin{cases} t^{\deg(f)} \text{ if } f \neq 0 \\ 0 \text{ if } f = 0 \end{cases}$$

(iii) Finally we introduce the **leading term** $\operatorname{lt}(f) \in R[t \mid A]$ of $f \in R[t \mid A]$ to be $f[\alpha]\, t^\alpha$ for this maximal $\alpha = \deg(f)$ again. If $f = 0$, we let $\operatorname{lt}(f) := 0 \in R[t \mid A]$, as before. Therefore we can either take $\operatorname{lt}(f) = \operatorname{lc}(f) \operatorname{lt}(f)$ or explicitly define $\operatorname{lt}(f)$ to be

$$\operatorname{lt}(f) := \begin{cases} f[\deg(f)]\, t^{\deg(f)} \text{ if } f \neq 0 \\ 0 \text{ if } f = 0 \end{cases}$$

Note if we are dealing with several total orders e.g. $\leq_1$ and $\leq_2$ then we will use subscripts such as $\deg_1$ or $\operatorname{lc}_2, \ldots$ to denote which of these orders we refer to.

(7.18) Proposition: (viz. 812)
Let $(R,+,\cdot)$ be any commutative ring, $(A,+)$ be a commutative monoid equipped with a positive order $\leq$ and let $f, g \in R[t \mid A]$ be two polynomials. Then the following (in)equalities hold true

$$\begin{aligned} \deg(f+g) &\leq \max\{\deg(f), \deg(g)\} \\ \deg(f \cdot g) &\leq \deg(f) + \deg(g) \\ \operatorname{lt}(f) &= \operatorname{lc}(f) \cdot \operatorname{lm}(f) \end{aligned}$$

If R is an integral domain and A is integral, too then the leading coefficient of the product $f \cdot g$ is the product of the leading terms of f and g and hence we obtain some further, noteworthy equalities

$$\begin{aligned} \deg(f \cdot g) &= \deg(f) + \deg(g) \\ \operatorname{lc}(f \cdot g) &= \operatorname{lc}(f) \cdot \operatorname{lc}(g) \\ \operatorname{lm}(f \cdot g) &= \operatorname{lm}(f) \cdot \operatorname{lm}(g) \\ \operatorname{lt}(f \cdot g) &= \operatorname{lt}(f) \cdot \operatorname{lt}(g) \end{aligned}$$

Nota even if R is any commutative ring (not necessarily an integral domain) and A is integral, then the four equalities above hold true, if at least on of the polynomials f or g is monic.

(7.19) Remark:
In the proof of (7.18) we even saw a little more: If R is an arbitrary commutative ring (not necessarily an integral domain) we obtain the equality for the degree in most cases, namely if the leading coefficients do not cancel each other. That is if $f, g \in R[t \mid A]$ are two polynomials, then we still get the implications

$$\begin{aligned} \operatorname{lc}(f) + \operatorname{lc}(g) \neq 0 \quad &\Longrightarrow \quad \deg(f+g) \;=\; \max\{\, \deg(f), \deg(g) \,\} \\ \operatorname{lc}(f) \cdot \operatorname{lc}(g) \neq 0 \quad &\Longrightarrow \quad \deg(f \cdot g) \;=\; \deg(f) + \deg(g) \end{aligned}$$

However these implications are not very useful, as for general polynomials we just don't know anything about their leading coefficients. Yet for a monic f and non-zero $g \in R[t]$ we have $\operatorname{lc}(f) \cdot \operatorname{lc}(g) = \operatorname{lc}(g) \neq 0$ and hence $\deg(f \cdot g) = \deg(f) + \deg(g)$. Easy counterexamples, where the degree truly decreases, are easy to provide - e.g. consider the base ring $R := \mathbb{F}_6$ then

$$\begin{aligned} (t+1) + (-t+1) &= 2 \\ (2t+1) \cdot (3t-1) &= t-1 \end{aligned}$$

7.3 The Standard Cases

In the previous section we have introduced the notion of a polynomial ring $R[t \mid A]$ over an arbitrary commutative monoid A. We also studied ordered monoids at the beginning of this chapter. The most important case however is the monoid $\mathbb{N}^{\oplus I}$ which has been introduced in example (7.5). This monoid is commutative, integral and solution finite and e.g. the graded lexicographic order is a positive well-ordering on it. This monoid will give rise to the polynomial ring $R[t_i \mid i \in I]$ which can be seen as the base ring R to which I-many algebraically independent elements t_i have been added. In complete analogy to the construction of $\mathbb{N}^{\oplus I}$ we will regard the monoid (in fact even a free group) $\mathbb{Z}^{\oplus I}$

$$\mathbb{Z}^{\oplus I} \quad := \quad \left\{ \alpha \in \mathbb{Z}^I \mid \#\{ i \in I \mid \alpha_i \neq 0 \} < \infty \right\}$$

If I is finite, say $I = 1 \dots n$, then it is clear, that $\mathbb{Z}^{\oplus(1\dots n)} = \mathbb{Z}^n$. We now turn this set into a commutative group by taking to the same point-wise addition as on $\mathbb{N}^{\oplus I}$, that is

$$(\alpha_i) + (\beta_i) \quad := \quad (\alpha_i + \beta_i)$$

Note that $\mathbb{Z}^{\oplus I}$ and $\mathbb{Z}^n$ are commutative, integral monoids, but neither of them is solution-finite. Hence the module of power series over these monoids do not form a well-defined ring.

(7.20) Definition:
Let $(R, +, \cdot)$ be a commutative ring, then we define some abbreviations and slightly different notations for the polynomial and formal power series rings of R over the monoids $\mathbb{N}^{\oplus I}$ and $\mathbb{Z}^{\oplus I}$

- For a non-empty index set $I \neq \emptyset$ we denote the polynomial ring resp. formal power series ring of R over the monoid $\mathbb{N}^{\oplus I}$ and specifically for $I = 1 \dots n$ we also denote the polynomial resp. formal power series ring of R over the monoid $\mathbb{N}^n$ by

$$\begin{aligned} R[t_i \mid i \in I] &:= R[t \mid \mathbb{N}^{\oplus I}] \\ R[t_1, \dots, t_n] &:= R[t \mid \mathbb{N}^n] \\ R[\![t_i \mid i \in I]\!] &:= R[\![t \mid \mathbb{N}^{\oplus I}]\!] \\ R[\![t_1, \dots, t_n]\!] &:= R[\![t \mid \mathbb{N}^n]\!] \end{aligned}$$

 Nota as we have already seen in (7.12) $R[t_i \mid i \in I]$ and $R[\![t_i, \mid i \in I]\!]$ are integral domains, iff the base ring R is an integral domain [as $A = \mathbb{N}^{\oplus I}$ always is integral and solution-finite].

- The symbols t_i in the above two definitions can be given a concrete meaning: Define t_i to be the monomial $t_i := t^{\delta_i}$ where $\delta_i = (\delta_{i,j}) \in \mathbb{N}^{\oplus I}$ then any other monomial t^α where $\alpha = (\alpha_i) \in \mathbb{N}^{\oplus I}$ is a finite product of the form

$$t^\alpha \quad = \quad \prod_{i \in I} t_i^{\alpha_i}$$

 Prob it is clear that $\alpha = \sum_i \alpha_i \delta_i$ and in truth this sum is finite only, as only finitely many $\alpha_i \neq 0$ are non-zero. But since $t^{\alpha+\beta} = t^\alpha t^\beta$ is true for any $\alpha, \beta \in \mathbb{N}^{\oplus I}$ this implies $t^\alpha = \prod_i t^{\alpha_i \delta_i}$ by induction on the number of non-zero α_i. But since $\alpha_i \delta_i = \delta_i + \dots + \delta_i$ (α_i-times) again, we likewise see $t^{\alpha_i \delta_i} = t_i^{\alpha_i}$ by induction the power α_i now. Altogether we found $t^\alpha = \prod_i t^{\alpha_i \delta_i} = \prod_i t_i^{\alpha_i}$.

- Let $I \neq \emptyset$ be a non-empty index set again. Then we denote the polynomial rings over the monoids (even groups) $\mathbb{Z}^{\oplus I}$ and $\mathbb{Z}^n$ by

$$\begin{aligned} R[t_i, t_i^{-1} \mid i \in I] &:= R[t \mid \mathbb{Z}^{\oplus I}] \\ R[t_1, t_1^{-1} \ldots, t_n, t_n^{-1}] &:= R[t \mid \mathbb{Z}^n] \end{aligned}$$

 Nota again we have seen that these rings are integral domains, iff R is an integral domain itself. Note however that the multiplication of the formal power series $R[\![t \mid \mathbb{Z}^{\oplus I}]\!]$ is not well-defined (as $\mathbb{Z}^{\oplus I}$ is *not* solution-finite), even if I is finte. Hence we do not need to introduce the like notation for formal power series over the monoid $\mathbb{Z}^{\oplus I}$.

(7.21) Remark:
The most important case is the polynomial ring $R[t_1, \ldots, t_n]$ in n variables over R, so let us linger and reflect the above definition in this case: First of all the variable symbols t_1 to t_n are maps of the form

$$t_1 \; : \; \mathbb{N}^n \to R \; : \; \alpha \mapsto \begin{cases} 1 \text{ if } \alpha = (1, 0, \ldots, 0) \\ 0 \text{ if else} \end{cases}$$

$$t_n \; : \; \mathbb{N}^n \to R \; : \; \alpha \mapsto \begin{cases} 1 \text{ if } \alpha = (0, \ldots, 0, 1) \\ 0 \text{ if else} \end{cases}$$

Thus by definition of the multiplication of $R[t_1, \ldots, t_n]$ we find the following equality for any multi-index $\alpha = (\alpha_1, \ldots, \alpha) \in \mathbb{N}^n$ (we have just proved this in the definition above)

$$t_1^{\alpha_1} \ldots t_n^{\alpha_n} \;\; = \;\; t^\alpha$$

where $t^\alpha : \mathbb{N}^n \to R$ is the usual map that sends $\alpha \mapsto 1$ and any $\beta \in \mathbb{N}^n$ with $\beta \neq \alpha$ is sent to $\beta \mapsto 0$. Thereby any polynomial $f \in R[t_1, \ldots, t_n]$ can be written, as the following (in truth finite) sum

$$f \;\; = \;\; \sum_{\alpha \in \mathbb{N}^n} f[\alpha]\, t^\alpha \;\; = \;\; \sum_{\alpha_1 = 0}^{\infty} \cdots \sum_{\alpha_n = 0}^{\infty} f[\alpha_1, \ldots, \alpha_n]\, t_1^{\alpha_1} \ldots t_n^{\alpha_n}$$

Any formal power series $f \in R[\![t_1, \ldots, t_n]\!]$ can be written in precisely the same form, but the sum need not be finite in this case. However it is still possible to multiply two such expressions, as the base monoid $\mathbb{N}^n$ is integral and solution finite. So by construction of the polynomial ring $\{\, t^\alpha \mid \alpha \in \mathbb{N}^n \,\}$ is an R-basis of $R[t_1, \ldots, t_n]$, but not a generating set of $R[\![t_1, \ldots, t_n]\!]$. Yet the main difference between polynomials and formal power series becomes apparent, if we try to evaluate f:
If A is a commutative R-algebra and $x_1, \ldots, x_n \in A$ are elements of it, then we can insert these into a polynomial $f \in R[t_1, \ldots, t_n]$, getting a new element of A. Recall that we have already introduced the notation $x^\alpha := x_1^{\alpha_1} \ldots x_n^{\alpha_n}$ early on in (1.41). This notation now fits perfectly, as it allows to rewrite the sum in terms of multi-indices $\alpha = (\alpha_1, \ldots, \alpha) \in \mathbb{N}^n$ again

$$f(x_1, \ldots, x_n) \;\; = \;\; \sum_{\alpha_1 = 0}^{\infty} \cdots \sum_{\alpha_n = 0}^{\infty} f[\alpha_1, \ldots, \alpha_n]\, x_1^{\alpha_1} \ldots x_n^{\alpha_n} \;\; = \;\; \sum_{\alpha \in \mathbb{N}^n} f[\alpha]\, x^\alpha \;\; \in \;\; A$$

Thereby the addition and multiplication of polynomials have been defined precisely in such a way, that $R[t_1,\ldots,t_n] \to A : f \mapsto f(x_1,\ldots,x_n)$ is a homomorphism of R-algebras, according to (7.14). It is *not* possible to insert x_1 to x_n into a formal power series $f \in R[\![t_1,\ldots,t_n]\!]$ though, as in general the sum will not be finite in this case! To do so would require to install a notion of convergence on A and to select those power series for which $f(x_1,\ldots,x_n)$ converges. This is a topic of a course in analysis, by nature.

(7.22) Proposition: (viz. 814)
Let $(R,+,\cdot)$ be a commutative ring, J be an arbitrary index set and $I \subseteq J$ be a subset of J. Then we have a canonical embedding (an R-algebra monomorphism) of the form

$$\begin{array}{rcl} R[t_i \mid i \in I] & \hookrightarrow & R[t_j \mid j \in J] \\ f & \mapsto & \left(\beta \mapsto \begin{cases} f[\beta] & \text{if} \quad \forall\, j \in J \setminus I : \beta(j) = 0 \\ 0 & \text{if} \quad \exists\, j \in J \setminus I : \beta(j) \neq 0 \end{cases} \right) \end{array}$$

And if R is an integral domain and we consider $R[t_i \mid i \in I] \leq_{\mathrm{r}} R[t_j \mid i \in J]$ as a sub-ring under this embedding, then $R[t_i \mid i \in I]$ also is a saturated multiplicatively closed set in $R[t_j \mid j \in J]$. That is for any $f, g \in R[t_j \mid i \in J]$ with $f, g \neq 0$ we have the equivalence

$$f \text{ and } g \in R[t_i \mid i \in I] \iff fg \in R[t_i \mid i \in I]$$

(7.23) Proposition: (viz. 810)

(i) Consider a commutative ring $(R,+,\cdot)$ and any non-empty index set $I \neq \emptyset$. The set of finite subsets of I is denoted by $\Omega(I) := \{\, \omega \subseteq I \mid \#\omega < \infty \,\}$. For any $\omega \in \Omega(I)$ we consider $R[t_i \mid i \in \omega]$ as a subring of $R[t_i \mid i \in I]$, by (7.22). Then any polynomial $f \in R[t_i \mid i \in I]$ is contained in one of the finitely generated subrings $R[t_i \mid i \in \omega]$, and therefore

$$R[t_i \mid i \in I] \;=\; \bigcup_{\omega \in \Omega(I)} R[t_i \mid i \in \omega]$$

(ii) Let $(R,+,\cdot)$ be any commutative ring an fix $1 \geq n \in \mathbb{N}$ and $i, j \in 1 \ldots n$. Then we regard $R[t_1,\ldots,t_j]$ and $R[t_i,\ldots,t_n]$ as sub-rings of $R[t_1,\ldots,t_n]$. And thereby we get

$$R[t_1,\ldots,t_j] \cap R[t_i,\ldots,t_n] \;=\; R[t_i,\ldots,t_j]$$

In particular, iff $j < i$ the only polynomials $f \in R[t_1,\ldots,t_n]$ that lie in both $R[t_1,\ldots,t_j]$ and $R[t_i,\ldots,t_n]$ are the constant ones $f \in R$.

(iii) For any commutative ring $(R,+,\cdot)$ we obtain an epimorphism of R-algebras from the formal power series in arbitrary many variables onto R by evaluation of the *constant term* $f[0]$ of f:

$$\varepsilon \;:\; R[\![t_i \mid i \in I]\!] \twoheadrightarrow R \;:\; f \mapsto f[0]$$

(iv) For any commutative ring $(R,+,\cdot)$ the ring of power series in $n+1$ variables is isomorphic (as an R-algebra) to a ring of power series in 1 variable over a ring of power series in n variables

$$\Phi \;:\; R[\![t_1,t_2,\ldots,t_n]\!][\![t_{n+1}]\!] \quad \cong_{\mathsf{r}} \quad R[\![t_1,t_2,\ldots,t_{n+1}]\!]$$

And this isomorphism Φ is given by $\Phi(f) : \alpha \mapsto f[\alpha_{n+1}]\,[\alpha_1,\alpha_2,\ldots,\alpha_n]$. In particular Φ restricts to an isomorphism between the respective polynomial rings

$$\Phi \;:\; R[t_1,t_2,\ldots t_n][t_{n+1}] \quad \cong_{\mathsf{a}} \quad R[t_1,t_2,\ldots,t_{n+1}]$$

(v) Let again $(R,+,\cdot)$ be a commutative ring and fix any n-tuple of elements $a=(a_1,\ldots,a_n)\in R^n$, then we obtain an R-algebra automorphism on the polynomial ring in n variables by

$$\Phi_a \;:\; R[t_1,t_2,\ldots,t_n] \quad \cong_{\mathsf{r}} \quad R[t_1,t_2,\ldots,t_n] \;:\; f(t)\mapsto f(t+a)$$

(vi) If $(R,+,\cdot)$ is a commutative ring and $a=(a_1,\ldots,a_n)\in R^n$ again, then we also get: Given any $f\in R[t_1,t_2,\ldots,t_n]$ there are some polynomials $q_k\in R[t_1,\ldots,t_k]$ (for $k\in 1\ldots n$) such that f can be written in the following form

$$f(t_1,\ldots,t_n) \;=\; \sum_{k=1}^{n} q_k(t_1,\ldots,t_k)(t_k-a_k)+f(a)$$

(vii) If $(R,+,\cdot)$ is an integral domain then the invertible elements of the polynomial ring in finitely many variables are just the constant polynomials of invertible elements of R

$$R[t_1,\ldots,t_n]^* \;=\; \{\, a\mathbf{1} \mid a\in R^*\,\}$$

(viii) And for any commutative ring $(R,+,\cdot)$ the invertible formal power series in finitely many variables are those whose degree constant term is invertible in R

$$R[\![t_1,\ldots,t_n]\!]^* \;=\; \{\, f\in R[\![t_1,\ldots,t_n]\!] \mid f[0]\in R^*\,\}$$

(7.24) Remark:

- If we are given a formal power series f (in the variable t_{n+1}) over the ring $R[\![t_1,\ldots,t_n]\!]$ of formal power series in the variables t_1 to t_n, then we first express f in the form

$$f=\sum_{\alpha_{n+1}\in\mathbb{N}}\left(\sum_{\alpha\in\mathbb{N}^n} f[\alpha_{n+1}]\,[\alpha_1,\ldots,\alpha_n]\,t_1^{\alpha_1}t_2^{\alpha_2}\ldots t_n^{\alpha_n}\right)t_{n+1}^{\alpha_{n+1}}$$

Using this formal "basis representation" of f the image $\Phi(f)$ under the isomorphism Φ in (ii) simply reads as the following power series in $n+1$ variables:

$$\Phi(f) \;=\; \sum_{\alpha\in\mathbb{N}^{n+1}} f[\alpha_{n+1}]\,[\alpha_1,\ldots,\alpha_n]\,t_1^{\alpha_1}t_2^{\alpha_2}\ldots t_{n+1}^{\alpha_{n+1}}$$

- As $A := R[t_1, \ldots, t_n]$ is an R-algebra, it is clear what we mean by the term $f(t+a)$ for a polynomial $f \in R[t_1, \ldots, t_n]$: Namely $t + a = (t_1 + a_1, \ldots, t_n + a_n)$ is an n-tuple of elements of A and hence we may evaluate f on this tuple, that is

$$f(t+a) \;=\; \sum_{\alpha \in \mathbb{N}^n} f[\alpha]\,(t_1+a_1)^{\alpha_1} \,\ldots\, t_n^{\alpha_n}(t_n+a_n)^{\alpha_n}$$

- The big brother of (7.23.(iv)) is (7.12.(vi)) and if I and J are any non-empty index sets, such that $I \cap J = \emptyset$, [e.g. $I \subseteq K$ and $J := K \setminus I$] then clearly $\mathbb{N}^{\oplus I} \times \mathbb{N}^{\oplus J} = \mathbb{N}^{\oplus (I \cup J)}$. Thus by (7.12.(vi)) we obtain an isomorphism of R-algebras

$$R[s_i \mid i \in I][t_j \mid j \in J] \quad \cong_{\mathrm{r}} \quad R[u_k \mid k \in I \cup J]$$

 And thereby the isomorphism maps t^β to $u^{(0,\beta)}$ and $s^\alpha \mathbf{1} \in R[s_i \mid i \in I][t_j \mid j \in J]$ to $u^{(\alpha,0)}$. The rest is just expansion of this map from the generating elements to the entire ring

$$\sum_{\beta \in \mathbb{N}^{\oplus J}} \left(\sum_{\alpha \in \mathbb{N}^{\oplus I}} f[\beta][\alpha] s^\alpha \right) t^\beta \;\;\mapsto \sum_{(\alpha,\beta) \in \mathbb{N}^{\oplus I} \times \mathbb{N}^{\oplus J}} f[\beta][\alpha] u^{(\alpha,\beta)}$$

 In particular we obtain a canonical embedding of $S := R[s_i \mid i \in I]$ into $R[u_k \mid k \in I \cup J]$, that is an injective monomorphism of rings, by virtue of

$$R[s_i \mid i \in I] \;\hookrightarrow\; R[u_k \mid k \in I \cup J] \;:\; f \mapsto f\mathbf{1}_{S[t_j \mid j \in J]}$$

- In the case of one variable only we can recursively compute the inverse f^{-1} of an invertible power series $f \in R[\![t]\!]^*$ by the following recursion formula. In the case of finitely many variables the inverse of $f \in R[\![t_1, \ldots, t_n]\!]^*$ can be computed sequentially using the isomorphism given in (ii).

$$\begin{aligned} f^{-1}[0] &= f[0]^{-1} \\ f^{-1}[n] &= -f[0]^{-1} \sum_{i=0}^{n-1} f[n-i]\, f^{-1}[i] \end{aligned}$$

(7.25) Definition:
Let $(R, +, \cdot)$ be a commutative ring and regard the polynomial ring in n variables $R[t_1, \ldots, t_n]$. Also fix some *weight* $\omega \in \mathbb{N}^n$ and recall the *weighted sum* of $\alpha \in \mathbb{N}^n$ to be

$$|\alpha|_\omega \;:=\; \omega_1\alpha_1 + \cdots + \omega_n\alpha_n$$

Then for a polynomial $f \in R[t_1, \ldots, t_n]$ we define the **(unordered) degree** $\deg_\omega(f) \in \mathbb{N} \cup -\infty$ of f under the weight $\omega \in \mathbb{N}^n$ to be the maximum weighted sum $|\alpha|_\omega$ among all multi-indices α that contribute a non-zero coefficient $f[\alpha] \neq 0$ to f. Formally, that is

$$\deg_\omega(f) \;:=\; \begin{cases} \max\{\, |\alpha|_\omega \mid \alpha \in \mathbb{N}^n,\, f[\alpha] \neq 0 \,\} & \text{for } f \neq 0 \\ -\infty & \text{for } f = 0 \end{cases}$$

For ease of notation we further introduce some specific unordered degrees of some specific weights ω

$$\begin{array}{rcllcrcl}
\deg(f) & := & \deg_\omega(f) & \text{for} & \omega & := & (1) & = & (1,1,\ldots,1) \\
\deg_j(f) & := & \deg_\omega(f) & \text{for} & \omega & := & (\delta_{i,j}) & = & (0,\ldots,1,\ldots,0) \\
\operatorname{wgt}(f) & := & \deg_\omega(f) & \text{for} & \omega & := & (i) & = & (1,2,\ldots,n)
\end{array}$$

(7.26) Proposition: (viz. 813)
Let R be a commutative ring, $1 \leq n \in \mathbb{N}$ and fix any $\omega \in \mathbb{N}^n$. Then for any $a \in R$ and any two polynomials $f, g \in R[t_1,\ldots,t_n]$ the unordered degree satisfies the following four properties

$$\begin{aligned}
\deg_\omega(at^\alpha) &= \begin{cases} |\alpha|_\omega \text{ if } a \neq 0 \\ -\infty \text{ if } a = 0 \end{cases} \\
\deg_\omega(f) &= \max\{\, \deg_\omega(f[\alpha]t^\alpha) \mid \alpha \in \mathbb{N}^n \,\} \\
\deg_\omega(f+g) &\leq \max\{\, \deg_\omega(f), \deg_\omega(g) \,\} \\
\deg_\omega(f \cdot g) &\leq \deg_\omega(f) + \deg_\omega(g)
\end{aligned}$$

If $\deg_\omega(f) \neq \deg_\omega(g)$ then this even implies the equality in the degree of the sum $f+g$, that is we get $\deg_\omega(f+g) = \max\{\, \deg_\omega(f), \deg_\omega(g) \,\}$. And if R is an integral domain or f or g is monic, then we always have equality of these for the degree of the product $f \cdot g$, that is we get

$$\deg_\omega(f \cdot g) = \deg_\omega(f) + \deg_\omega(g)$$

(7.27) Proposition: (viz. 817)

(i) Let $(R,+,\cdot)$ be an integral domain and consider two polynomials $f, g \in R[t]$ with $f \neq 0$. Then $g(f) \in R[t]$ is another polynomial in $R[t]$ and its degree is given to be

$$\deg\big(g(f)\big) = \deg(f) \cdot \deg(g)$$

(ii) If $(R,+,\cdot)$ is an integral domain again and $f \in R[t_1,\ldots,t_n]$ is a polynomial in $n \in \mathbb{N}$ variables of $\deg(f) \geq 1$ and $g \in R[x]$ is a polynomial in one variable, then we get the equivalence of

$$g(f) = 0 \iff g = 0$$

Now let $(R,+,\cdot)$ be a commutative ring, $I \neq \emptyset$ an index set and denote $A := R[t_i \mid i \in I]$ the polynomial ring. We consider $R \subseteq A : a \mapsto a\mathbf{1}$ canonically. Then we obtain the following statements

(iii) Any $p \in R$ is prime in R if and only if $p = p\mathbf{1} \in A$ is prime, that is: $p \in R$ prime $\iff$ $p \in A$ prime.

(iv) Let R be an integral domain and fix $i \in I$ and $a_i \in R$, then $t_i - a_i \in A$ is a prime element of A.

(v) Once more let R be an integral domain and fix any $i \in I$, then $t_i A \trianglelefteq_{\mathrm{i}} A$ is a minimal prime ideal over $0 \trianglelefteq_{\mathrm{i}} A$. That is for any prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} A$ we have the implication

$$0 \subseteq \mathfrak{p} \subseteq t_i A \implies \mathfrak{p} = 0 \text{ or } \mathfrak{p} = t_i A$$

(7.28) Proposition: (viz. 814)
Let $(R,+,\cdot)$ be a commutative ring and $f \in R[t_1,\ldots,t_n]$ be a polynomial in $1 \leq n \in \mathbb{N}$ variables. Then there are polynomials $f_1,\ldots,f_n$ such that (for any $k \in 1\ldots n$) we get (1) $f_k \in R[t_1,\ldots,t_k]$ and (2) $\deg(f_k) < \deg(f)$ and (3) f has a decomposition in the following form

$$f \;=\; f(0) + \sum_{k=1}^{n} f_k(t_1,\ldots,t_k)t_k$$

In particular the polynomial ring $R[t_1,\ldots,t_n]$ can be decomposed into $R\,\mathbf{1}$ and a sum of prime ideals

$$R[t_1,\ldots,t_n] \;=\; R\,\mathbf{1} + \sum_{k=1}^{n} t_k R[t_1,\ldots,t_n]$$

(7.29) Lemma: (viz. 820)
Let $(R,+,\cdot)$ be an UFD, denote its quotient field by $E := \mathrm{QUOT}(R)$, and consider $R \subseteq E : a \mapsto a/1$ canonically. Also let $I \neq \emptyset$ be any index set and denote the polynomial rings $A := R[t_i \mid i \in I]$ and $B := E[t_i \mid i \in I]$. In particular $A \subseteq B$. We also consider $R \subseteq A : a \mapsto a\mathbf{1}$ canonically. Finally recall (5.26) where $f \in A$ was said to be *primitive* iff $f \neq 0$ and $1 \in \mathrm{cont}(f)$. Thereby the *content* of $f \in A$ (as an element of a free module) has been defined to be

$$\mathrm{cont}(f) \;=\; \gcd\{\, f[\alpha] \mid \alpha \in \mathbb{N}^{\oplus I},\, f[\alpha] \neq 0 \,\}$$

(i) Consider $a \in R$ and $f \in A$, then a divides f (in A) if and only if a divides the content $\mathrm{cont}(f)$ of f (in R). That is for any $c \in \mathrm{cont}(f)$ we have the following equivalence of

$$a \mid c \;\text{ in } R \quad\Longleftrightarrow\quad a \mid f \;\text{ in } A$$

(ii) For any polynomial $f \in A$ and any $c \in R$ we find that c is the content of f if and only iff $f = cf_1$ for some primitive polynomial $f_1 \in A$

$$c \in \mathrm{cont}(f) \quad\Longleftrightarrow\quad \exists\, f_1 \in A \;:\; f = cf_1 \;\text{ and }\; f_1 \;\text{ primitive}$$

(iii) If $u \in B$ with $u \neq 0$ is a non-zero polynomial over the quotient field E, then there are some a, $b \in R \setminus \{0\}$ and a primitive polynomial $u_1 \in A$ such that u can be written, as

$$u \;=\; \frac{a}{b}u_1$$

(iv) The content of polynomials is multiplicative. That is for any polynomials $f, g \in A$ with $c \in \mathrm{cont}(f)$ and $d \in \mathrm{cont}(g)$ we have $cd \in \mathrm{cont}(fg)$. In particular the set $U := \{\, f \in A \mid f \text{ primitive} \,\}$ of primitive polynomials is a multiplicatively closed set in A.

(v) Let us abbreviate either the word *primitive* or *monic* by $\star$ and consider $u, v \in E[t]$ any polynomials over E, such that the product $uv \in E[t]$ in fact is a $\star$ polynomial of $R[t]$, formally

$$uv \in R[t] \;\text{ and }\; uv \text{ is } \star$$

Then there are a, b, c and $d \in R \setminus \{0\}$ and polynomials u_1, $v_1 \in R[t]$ that satisfy the properties

(1) u and $v \in R[t]$ are $\star$

(2) $u = \frac{a}{b}u_1$ and $v = \frac{c}{d}v_1$

(3) $uv = u_1v_1$

(vi) If $p \in A$ is primitive and $f \in A$ is any polynomial then p divides f in A if and only if p divides f in B - that is the equivalence given below. In fact, if $f = pq$ for some $q \in B$, then $q \in A$ already.

$$p \mid f \text{ in } A \iff p \mid f \text{ in } B$$

(vii) Let $p \in A \setminus R$ be primitive and let $\star$ abbreviate one of the words *prime* or *irreducible*. Then $p \in A$ is $\star$ in A if and only if it is $\star$ in B, formally again

$$p \in A \text{ is } \star \iff f \in B \text{ is } \star$$

(viii) *Lemma of Gauss*: If the base ring R is a factorial domain, then the polynomial ring A is a factorial domain, too and vice versa. That is the following equivalence

$$R \text{ is an UFD} \iff A \text{ is an UFD}$$

Laurent Series

Until now we have regarded polynomial rings $R[t]$, formal series $R[\![t]\!]$ and even $R[t, t^{-1}]$. In complex analysis and p-adic analysis there even occur mixtures of these structures - so called Laurent series. We are not particularly interested in them, but they are important enough to not go unmentioned here.

(7.30) Proposition: (viz. 824)

Let $(R, +, \cdot)$ be a commutative ring, fix a natural number $1 \leq n \in \mathbb{N}$ and let us abbreviate the module $M := R[\![t \mid \mathbb{Z}^n]\!]$ of formal power series over $\mathbb{Z}^n$ with coefficients in R. Then we introduce the notions

(i) A formal power series $f \in M$ is said to be a **(formal) Laurent series**, iff its negative powers do not drop indefinitely, i.e. they don't proceed below some finite degree ℓ. Formally that is:

$$\exists\, \ell \in \mathbb{Z} \;:\; \forall\, \alpha \in \mathbb{Z}^n \text{ with } f[\alpha] \neq 0 \text{ we get } \forall\, i \in 1 \ldots n \;:\; \ell \leq \alpha_i$$

The set $L := \{\, f \in M \mid f \text{ is a formal Laurent series} \,\}$ of all Laurent series is a sub-module of M. In fact it even becomes a commutative ring under the usual multiplication

$$\left(\sum_{\alpha \in \mathbb{Z}^n} f[\alpha] t^\alpha \right) \cdot \left(\sum_{\beta \in \mathbb{Z}^n} g[\beta] t^\beta \right) \;=\; \sum_{\gamma \in \mathbb{Z}^n} \left(\sum_{\alpha+\beta=\gamma} f[\alpha]\, g[\beta] \right) t^\gamma$$

(ii) This construction allows us to define the order of a formal laurent series $f \in L$ (where $f \neq 0$). Fix some weight $\omega \in \mathbb{N}^n$ and define the **(weighted) order** of f to be the minimal weight of an non-zero coefficient of f, formally that is

$$\operatorname{ord}_\omega(f) \;:=\; \min\{\, |\alpha|_\omega \mid \alpha \in \mathbb{Z}^n,\ f[\alpha] \neq 0 \,\}$$

If such an index does not exist, i.e. in the case $f \in M \setminus L$ we formally take the order to be $\operatorname{ord}_\omega(f) := -\infty$ and as a very special case, we let $\operatorname{ord}_\omega(0) := \infty$.

(iii) The weighted order on L has most of the properties of a valuation: It is sub-additive and sub-multiplicative. I.e. for any $\omega \in \mathbb{N}^n$ and any two Laurent series $f, g \in L$ we get

$$\begin{aligned} \operatorname{ord}_\omega(f) + \operatorname{ord}_\omega(g) &\leq \operatorname{ord}_\omega(f\,g) \\ \min\{\, \operatorname{ord}_\omega(f), \operatorname{ord}_\omega(f) \,\} &\leq \operatorname{ord}_\omega(f+g) \\ \operatorname{ord}_\omega(-f) &= \operatorname{ord}_\omega(f) \end{aligned}$$

And if R is an integral domain, then the order even is multiplicative, that is we get the property

$$\operatorname{ord}_\omega(f\,g) \;=\; \operatorname{ord}_\omega(f) + \operatorname{ord}_\omega(g)$$

(iv) Let us abbreviate the ring of formal power series by $P := R[\![t \mid \mathbb{N}^n]\!]$. Then the subset of monoids $U = \{\, t^\alpha \mid \alpha \in \mathbb{N}^n \,\} \subseteq P$ is multiplicatively closed and the ring of formal Laurent series is isomorphic to the localization of P in U, formally

$$U^{-1}P \;\cong_{\mathrm{r}}\; L \;:\; \frac{f}{t^\alpha} \;\mapsto\; t^{-\alpha} f$$

(v) In the case $n = 1$, if R is a field we even get the following isomorphy between the quotient field of $R[\![t]\!]$ and the ring of formal Laurent series $L = R[\![t]\!][t^{-1}]$ by virtue of (where $\operatorname{ord} := \operatorname{ord}_{(1)}$)

$$\textsc{quot}\big(R[\![t]\!]\big) \;\cong_{\mathrm{f}}\; R[\![t]\!][t^{-1}] \;:\; \frac{f}{g} \;\mapsto\; t^{-\operatorname{ord}(f)} f \cdot (t^{-\operatorname{ord}(g)} g)^{-1}$$

Space of Arcs

We conclude this subsection by regarding powers and products of formal power series in one variable. We will compute an explicit formula for $f(a_1, \ldots, a_n)$ and study how the higher powers depend on the powers of the a_i. This is interesting for expansions of analytic functions as power series and for spaces of arcs on affine varieties. The letter is a method of analysing the higher-order curvature of an affine variety, much like a Taylor expansion analyses the curvature of a function. It is a little technical and not required to understand the rest of this textbook.

(7.31) Definition:
We fix $1 \leq n \in \mathbb{N}$ and consider any commutative ring $(R, +, \cdot)$, a polynomial $f \in R[t_1, \ldots, t_n]$ in n variables and n formal power series $a_1, \ldots, a_n \in R[\![\varepsilon]\!]$ in one variable ε over over R

$$\begin{aligned} f(t_1, \ldots, t_n) &= \sum_{\alpha \in \mathbb{N}^n} f[\alpha]\, t^\alpha \\ a_i(\varepsilon) &= \sum_{j=0}^{\infty} a_i[j]\, \varepsilon^j \end{aligned}$$

Let us denote the n-tuple $a := (a_1, \ldots, a_n) \in R[\![\varepsilon]\!]^n$ then we want to deprive a of its algebraic structure and only store the coefficients of the series a_i in the following form: Let $a[k] := (a_1[k], \ldots, a_n[k]) \in R^n$ for any $k \in \mathbb{N}$ and also define

$$\dot{a} \;:=\; (a[0],\, a[1],\, a[2],\, \ldots) \;\in\; \left(R^n\right)^{\mathbb{N}}$$

In the following, for any $k \in \mathbb{N}$, we want to define a function $\mathcal{L}_k$ that assigns a polynomial in the variables $t_{i,j}$, where $i \in 1 \ldots n$ and $j \in \mathbb{N}$ to a given polynomial $f \in R[t_1, \ldots, t_n]$. This will require some preparations, though: First of all, let us denote

$$\begin{aligned} B &:= \left(\mathbb{N}^{\oplus\mathbb{N}}\right)^n \\ P_n &:= R\left[t_{i,j} \mid i \in 1 \ldots n,\, j \in \mathbb{N}\right] \end{aligned}$$

Recall that $|\alpha| := \alpha_1 + \cdots + \alpha_n$ for a multi-index $\alpha \in \mathbb{N}^n$. We now need to transfer this notation to the case of multi-multi-indices. That is for $\beta = (\beta_1, \ldots, \beta_n) \in B$ we further define the following notations (where $\beta_i = (\beta_{i,0}, \beta_{i,1}, \beta_{i,2}, \ldots) \in \mathbb{N}^{\oplus\mathbb{N}}$)

$$|\beta| \;:=\; \left(\sum_{j=0}^{\infty} \beta_{1,j}, \ldots, \sum_{j=0}^{\infty} \beta_{n,j}\right) \;\in\; \mathbb{N}^n$$

$$\|\beta\| \;:=\; \sum_{i=1}^{n} \sum_{j=0}^{\infty} j\beta_{i,j} \;\in\; \mathbb{N}$$

As any β_i only has finitely many non-zero entries $\beta_{i,j} \neq 0$ the same is true for β and also $|\beta|$ and $\|\beta\|$ are well-defined. In fact, if if $\beta_{i,j} \neq 0$, then $\|\beta\| \geq j$ and hence we get $\beta_{i,j} = 0$ for any $i \in 1 \ldots n$ and $j > \|\beta\|$. Therefore for any $\alpha \in \mathbb{N}^n$ and any $k \in \mathbb{N}$ the following subset of B is finite

$$B(\alpha, k) \;:=\; \{\, \beta \in B \mid |\beta| = \alpha,\ \|\beta\| = k \,\}$$

If now $\beta \in B$ (as above) and $\alpha = (\alpha_1, \ldots, \alpha_n) \in \mathbb{N}^n$ satisfy $|\beta| = \alpha$ then we may define the binomial coefficient of α over β to be the following (note that the product in truth is finite, as $\beta_{i,j} = 0$ for all but finitely many $i \in 1 \ldots n$ and $j \in \mathbb{N}$, such that $\beta_{i,j}! = 1$ in this case)

$$\binom{\alpha}{\beta} \;:=\; \prod_{i=1}^{n} \binom{\alpha_i}{\beta_i} \;=\; \prod_{i=1}^{n} \alpha_i! \left(\prod_{j=0}^{\infty} \beta_{i,j}!\right)^{-1} \;\in\; \mathbb{N}$$

Finally consider some sequence $\dot{a} = (a_{i,j})$ where $a_{i,j} \in R$ and $i \in 1 \ldots n$, $j \in \mathbb{N}$ and let $\beta \in B$ be as

above. Then we generalize our notation of powers by multi-indices somewhat, to

$$t^\beta \;:=\; \prod_{i=1}^{n}\prod_{j=0}^{\infty} t_{i,j}^{\beta_{i,j}} \;\in\; P_n$$

$$\dot{a}^\beta \;:=\; \prod_{i=1}^{n}\prod_{j=0}^{\infty} a_{i,j}^{\beta_{i,j}} \;\in\; R$$

Using these notations let us define the function $\mathcal{L}_k : R[t_1,\ldots,t_n] \to P_n$ for any $k \in \mathbb{N}$ to be (note that this truly is a polynomial, as $f[\alpha] = 0$ for all but finitely many $\alpha \in \mathbb{N}^n$ and $B(\alpha,k)$ is a finite set)

$$\mathcal{L}_k(f) \;:=\; \sum_{\alpha\in\mathbb{N}^n}\sum_{\beta\in B(\alpha,k)} \binom{\alpha}{\beta} f[\alpha]\, t^\beta \;\in\; P_n$$

Nota and as $\beta_{i,j} = 0$ for any $j > \|\,\beta\,\| = k$ the polynomial $\mathcal{L}_k(f) \in P_n$ does not contain any of the variables $t_{i,j}$ whenever $j > k$. In other words $\mathcal{L}_k(f)$ is contained in the following sub-ring of P_n

$$\mathcal{L}_k(f) \;\in\; R[t_{i,j} \mid i \in 1\ldots n,\, j \in 0\ldots k]$$

(7.32) Proposition: (viz. 833)
Fix $n \in \mathbb{N}$ and let $a(\varepsilon), a_1(\varepsilon), \ldots, a_n(\varepsilon) \in R[\![\varepsilon]\!]$ be formal power series in one variable over the commutative ring R and let $f, g \in R[t_1,\ldots,t_n]$ be polynomials in n variables over R.

(i) Let $b_1(\varepsilon),\ldots,b_n(\varepsilon) \in R[\![\varepsilon]\!]$ be further formal power series such that b_i is identical to a_i up to some degree $l \in \mathbb{N}$, i.e. for all $i \in 1\ldots n$ and $k \in 0\ldots l$ we have $a_i[k] = b_i[k]$. Then $f(a_1,\ldots,a_n)$ and $f(b_1,\ldots,b_n)$ agree up to degree l as well:

$$\forall\, k \in 0\ldots l \quad \text{we get} \quad f(a_1,\ldots,a_n)[k] \;=\; f(b_1,\ldots,b_n)[k]$$

(ii) For a general polynomial $f \in R[t_1,\ldots,t_n]$ we use the notations of (7.31) introduced above and thereby obtain the expression

$$f(a_1,\ldots,a_n)(\varepsilon) \;=\; \sum_{k=0}^{\infty} \mathcal{L}_k(f)(\dot{a})\,\varepsilon^k$$

(iii) Then the map $f \mapsto \mathcal{L}_k(f)$ from $R[t_1,\ldots,t_n]$ to $R[t_{i,j} \mid i \in 1\ldots n,\, j \in 0\ldots k]$ clearly is R-linear and satisfies the following multiplicative property for any $f, g \in R[t_1,\ldots,t_n]$

$$\mathcal{L}_k(f\cdot g) \;=\; \sum_{i+k=k} \mathcal{L}_i(f)\cdot\mathcal{L}_j(g)$$

(iv) Suppose the $a_j(t)$ are of degree $l-1$ only, i.e. we regard the polynomials a_j and consider these polynomials with another (the l-th) term appended

$$\begin{aligned} a_j(\varepsilon) &= a_j[0] + a_j[1]\varepsilon + \cdots + a_j[l-1]\varepsilon^{l-1} \\ \overline{a}_j(\varepsilon) &:= a_j(\varepsilon) + a_j[l]\varepsilon^l \end{aligned}$$

Let $\partial_j f$ denote the formal derivative of f to the j-th variable t_j then the l-th coefficient of the evaluated expression $f(\overline{a}_1,\dots,\overline{a}_n)(\varepsilon)$ is modified as follows:

$$f(\overline{a})[l] \;=\; f(a)[l] + \sum_{j=1}^{n} (\partial_j f)(a[0]) \cdot a_j[l]$$

(7.33) Remark:
By construction $\mathcal{L}_k(f)$ is a polynomial in $P_n = R[t_{i,j} \mid i \in 1\dots n,\, j \in \mathbb{N}]$ in which no $t_{i,j}$ with $j > k$ appears. This is the reason why we may consider $\mathcal{L}_k(f) \in R[t_{i,j} \mid i \in 1\dots n,\, j \in 0\dots k]$ which we regard as a sub-ring of P_n. Therefore, if we evaluate $\mathcal{L}_k(f)$ on $\dot{a} = (a[0], a[1], a[2], \dots)$ in $\mathcal{L}_k(f)(\dot{a})$ there does not appear any coefficient $a_i[j] = t_{i,j}(\dot{a})$ for any index $j > k$. Hence we may omit $a[j]$ for any $j > k$ as in truth $\mathcal{L}_k(f)(\dot{a})$ only depends on $a[0]$ to $a[k]$

$$\mathcal{L}_k(f)\big(a[0], a[1], a[2], \dots\big) \;=\; \mathcal{L}_k(f)\big(a[0], a[1], \dots, a[k]\big)$$

(7.34) Example:
Let R be a commutative ring and consider the polynomial $f(t_1, t_2) := t_1^2 + t_2^2 - r^2$ defining a circle X of radius r around the origin of R^2. Also let $a_1 := a_1[0] + a_1[1]\varepsilon$ and $a_2 := a_2[0] + a_2[1]\varepsilon$ and append $\overline{a}_1 := a_1 + a_1[2]\varepsilon^2$ and $\overline{a}_2 := a_2 + a_2[2]\varepsilon^2$ respectively. Then an elementary computation yields

$$\begin{aligned}
f\big(a_1, a_2\big) \;&=\; \big(a_1[0]^2 + a_2[0]^2 - r^2\big) \\
&\quad + 2\big(a_1[0]a_1[1] + a_2[0]a_2[1]\big)\varepsilon \\
&\quad + \big(a_1[1]^2 + a_2[1]^2\big)\varepsilon^2 \\
f\big(\overline{a}_1, \overline{a}_2\big) \;&=\; \big(a_1[0]^2 + a_2[0]^2 - r^2\big) \\
&\quad + 2\big(a_1[0]a_1[1] + a_2[0]a_2[1]\big)\varepsilon \\
&\quad + \big(a_1[1]^2 + 2a_1[0]a_1[2] + 2a_2[0]a_2[2] + a_2[1]^2\big)\varepsilon^2 \\
&\quad + 2\big(a_1[1]a_1[2] + a_2[1]a_2[2]\big)\varepsilon^3 \\
&\quad + \big(a_1[2]^2 + a_2[2]^2\big)\varepsilon^4
\end{aligned}$$

From this we see that $f(a_1, a_2)$ and $f(\overline{a}_1, \overline{a}_2)$ share the same coefficients for $k = 0$ and $k = 1$, as predicted in (i). And for $k = 2$ we have $\partial_1 f = 2t_1$, such that $(\partial_1 f)(a[0]) \cdot a_1[2] = 2a_1[0]a_1[2]$, likewise $(\partial_2 f)(a[0]) \cdot a_2[2] = 2a_2[0]a_2[2]$. So, as predicted in (iv), we truly have

$$f\big(\overline{a}_1, \overline{a}_2\big)[2] \;=\; f\big(a_1, a_2\big)[2] + (\partial_1 f)(a[0]) \cdot a_1[2] + (\partial_2 f)(a[0]) \cdot a_2[2]$$

7.4 Graded Algebras

(7.35) Definition:
Let $(D,+)$ be a commutative monoid and $(R,+,\cdot)$ be a commutative ring. Then the ordered pair $(A,\deg)$ is said to be a D**-graded** R**-(semi)algebra**, iff it satisfies all of the following properties

(1) A is a commutative R-(semi)algebra

(2) $\deg : A_{\text{hom}} \to D$ is a function from some subset $A_{\text{hom}} \subseteq A$ to D, where we require $0 \notin A_{\text{hom}}$. Thereby an element $h \in A$ is said to be **homogeneous**, iff $h \in A_{\text{hom}} \cup \{0\}$.

(3) For any $d \in D$ let us denote $A_d := \deg^{-1}(d) \cup \{0\} \subseteq A$. Then we require that $A_d \leq_{\mathfrak{m}} A$ is an R-sub-module of A and that A is decomposed as an inner direct sum of sub-modules

$$A \;=\; \bigoplus_{d\in D} A_d$$

(4) Given any c, $d \in D$ we require that the product gh of the homogeneous elements g of degree c and h of degree d is a homogeneous element of degree $c+d$. That is: If we define the set of products $A_cA_d := \{\, gh \mid g \in A_c, h \in A_d \,\}$, then we require

$$A_cA_d \;\subseteq\; A_{c+d}$$

(7.36) Remark:

- By property (2) A_d is a sub-module of A, that is the sum $g+h$ of two homogeneous elements of degree d again is a homogeneous element of degree d. And likewise the scalar multiple ah is a homogeneous element of degree d as well. Thus for any g, $h \in A_{\text{hom}}$ with $\deg(g) = \deg(h)$ and any $a \in R$ such that $ag+h \neq 0$ we get

$$\deg(ag+h) \;=\; \deg(g) \;=\; \deg(h)$$

- Property (4) asserts that the product of homogeneous elements is homogeneous again, in particular $A_{\text{hom}} \cup \{0\}$ is closed under multiplication. And thereby the degree even is additive, that is for any two homogeneous elements g, $h \in A_{\text{hom}}$ we get

$$gh \neq 0 \quad\Longrightarrow\quad \deg(gh) = \deg(g) + \deg(h)$$

- According to (3) any element $f \in A$ has a unique decomposition in terms of homogeneous elements. To be precise, given any $f \in A$, there is a uniquely determined sequence of elements (f_d) (where $d \in D$) such that $f_d \in A_d$ (that is $f_d = 0$ or $\deg(f_d) = d$) the set $\{\, d \in D \mid f_d \neq 0 \,\}$ is finite and

$$f \;=\; \sum_{d\in D} f_d$$

 Thereby f_d is called the **homogeneous component** of degree d of f. And writing $f = \sum_d f_d$ we will often speak of the decomposition of f into homogeneous components.

- It is unsatisfactory to always distinguish the cases $h = 0$ when considering a homogeneous element $h \in A_{\text{hom}} \cup \{0\} \subseteq A$. Hence we will add the symbol $-\infty$ to D as outlined in (7.4). Then the degree can be extended canonically to all homogeneous elements

$$\deg \ : \ A_{\text{hom}} \cup \{0\} \to D \cup \{-\infty\} \ : \ h \mapsto \begin{cases} \deg(h) \text{ if } h \neq 0 \\ -\infty \text{ if } h = 0 \end{cases}$$

 If A is an integral domain this turns "deg" into a homomorphism of semigroups, from $A_{\text{hom}} \cup \{0\}$ (under the multiplication of A) to D. That is for any $g, h \in A_{\text{hom}} \cup \{0\}$ we now get

$$\deg(gh) \ = \ \deg(g) + \deg(h)$$

- In the literature it is customary to call the decomposition $A = \bigoplus_d A_d$ itself a D-graded R-algebra, supposed $A_c A_d \subseteq A_{c+d}$. But this clearly is equivalent to the definition we gave here. Just let

$$A_{\text{hom}} \ := \ \bigcup_{d \in D} A_d \setminus \{0\}$$

 Then we obtain a well-defined function $\deg : A_{\text{hom}} \to D$ by letting $\deg(h) := d$ where $d \in D$ is (uniquely) determined by $h \in A_d$. And thereby it is clear that $(A, \deg)$ becomes a D-graded R-algebra, with $\deg^{-1}(d) = A_d \setminus \{0\}$ again.

(7.37) Example:
If $(R, +, \cdot)$ is any commutative ring and $(D, +)$ is any commutative monoid (with neutral element 0), then there is a trivial construction turning R into a D-graded R-algebra. Just let $R_{\text{hom}} := R \setminus \{0\}$ and define the degree by $\deg : R_{\text{hom}} \to D : h \mapsto 0$. That is $R_0 = R$, whereas $R_d = 0$ for any $d \neq 0$. Thus examples of graded algebras abound, but of course this construction won't produce any new insights.

(7.38) Remark:
Given some commutative ring $(A, +, \cdot)$ [and a commutative monoid $(D, +)$] there are two canonical ways how to regard A as an R-algebra

(1) We could fix $R := A$, in this case the sub-modules $A_d \ \leq_{\mathfrak{m}} \ A$ occurring in property (3) would be ideals $A_d \ \trianglelefteq_{\mathfrak{i}} \ A$. So this would yield a quite peculiar property: As A_d is an ideal we have $A_c A_d \subseteq A_d$ but also $A_c A_d \subseteq A_{c+d}$ by property (4). But if $c + d \neq d$ then $A_{c+d} \cap A_d = \{0\}$ such that $A_c A_d = 0$. So homogeneous elements of non-zero degree have to delete each other by multiplication.

(2) Secondly we could fix $R := \mathbb{Z}$, in this case the sub-modules $A_d \ \leq_{\mathfrak{m}} \ A$ occuring in property (3) would only have to be subgroups $A_d \ \leq_{\mathfrak{g}} \ A$. Thus there no longer is a reference to the algebra structure of A. Hence we will also speak of a *D-graded ring* in this case.

(7.39) Example:
The classical example and the sole reason for the entire concept of graded algebras, is the following: Let $(R,+,\cdot)$ be any commutative ring, fix any $1 \leq n \in \mathbb{N}$ and let $A := R[t_1,\ldots,t_n]$ be the polynomial ring in n variables. Recall that the (standard) *degree* of a polynomial $f \in A$ with $f \neq 0$ is defined to be

$$\deg(f) \quad = \quad \max\{\, |\alpha| \mid \alpha \in \mathbb{N}^n,\, f[\alpha] \neq 0 \,\}$$

Now a polynomial $f \in A$ with $f \neq 0$ and $d := \deg(f) \in \mathbb{N}$ is said to be **homogeneous** iff all its monomials are of degree d. That is iff for any $\alpha \in \mathbb{N}^n$ we have the implication

$$f[\alpha] \neq 0 \quad \Longrightarrow \quad |\alpha| = d$$

In particular any monomial is homogeneous. Also $t_1^2 t_2^2 t_3 + t_1 t_3^4$ is an example of a homogeneous polynomial of degree 5. Yet $t_1 + t_1^3 \in R[t_1]$ is not homogeneous, as its monomials have different degree. Thereby the homogeneous polynomials of degree d (apart from 0) form the set

$$A_d \quad = \quad \mathrm{Lh}_R\{\, t^\alpha \in A \mid \alpha \in \mathbb{N}^n,\, |\alpha| = d \,\}$$

Thereby A becomes an $\mathbb{N}$-graded R-algebra, as all the A_d are sub-modules of R, that satisfy the multiplicative property $A_c A_d \subseteq A_{c+d}$ and A is the inner direct sum

$$A \quad = \quad \bigoplus_{d\in\mathbb{N}} A_d$$

(7.40) Proposition: (viz. 784)
Let $(R,+,\cdot)$ be a commutative ring m, $n \in \mathbb{N}$ where $n \geq 1$ and consider a polynomial $f \in R[t_1,\ldots,t_n]$, that is non-zero $f \neq 0$. Let $d := \deg_n(f)$ be the degree of x_n in f (that is the highest power of x_n occurring). Then the following two statements are equivalent

(a) f is a homogeneous polynomial of degree $m = \deg(f)$

(b) f can be written in the following form, where for any $k \in 0\ldots d$ any polynomial $f_k \in R[t_1,\ldots,t_{n-1}]$ is homogeneous of degree $\deg(f_k) = m - k$ or $f_k = 0$:

$$f(t_1,\ldots,t_n) \quad = \quad \sum_{k=0}^{d} f_k(t_1,\ldots,t_{n-1})\, t_n^k$$

In this case $f_d \neq 0$ is non-zero. For a general polynomial f, we can still write f in the form given in (b), but the f_k need not be homogeneous and only need to have $\deg(f_k) \leq m - k$.

Rees Algebra

The following construction will be twofold: For one we see that an ideal $\mathfrak{a}$ induces a metric on R, that turns R into a topological ring, if the intersection of the powers $\mathfrak{a}^n$ is zero. This construction is used in p-adic analysis, for example. And for a general ideal we can define the *Rees-algebra*, which is a $\mathbb{N}$-graded algebra. In case the intersection of the $\mathfrak{a}^n$ is zero, we can introduce a canonical map from R to the Rees-algebra. The Rees-algebra will later play a role in several theories like the Hilbert-Samuel polynomial and dimension theory of rings (in particular regular local rings).

(7.41) Definition:

Let $(R,+,\cdot)$ be a commutative ring and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be an ideal of R, then we say that $\mathfrak{a}$ is a **filter-ideal**, iff the intersection of all powers $\mathfrak{a}^n$ of $\mathfrak{a}$ is the zero-ideal (where for $n = 0$ we take $\mathfrak{a}^n := R$), that is

$$\bigcap_{n\in\mathbb{N}} \mathfrak{a}^n \;=\; \{0\}$$

Then it is clear, that any $a \in R$ with $a \neq 0$ is contained in a maximal power $\mathfrak{a}^n$ of the ideal $\mathfrak{a}$. And thereby we may define the **order** $\mathrm{ord}(a)$ of a to be that maximal power

$$\mathrm{ord} \;:\; R\setminus\{0\} \to \mathbb{N} \;:\; a \mapsto \max\Big\{\, k\in\mathbb{N} \mid a \in \mathfrak{a}^k \,\Big\}$$

Specifically for $a = 0$ we define $\mathrm{ord}(a) := \infty$. Then this map is well-defined, but need neither be additive, nor multiplicative. However it is super-additive and super-multiplicative, that is for any a, $b \in R$ we have

(1) $\mathrm{ord}(a+b) \;\geq\; \min\{\,\mathrm{ord}(a), \mathrm{ord}(b)\,\}$

(2) $\mathrm{ord}(ab) \;\geq\; \mathrm{ord}(a)\cdot\mathrm{ord}(b)$

Prob If $m = \mathrm{ord}(a)$ and $n = \mathrm{ord}(b)$ then $a \in \mathfrak{a}^m$ and $b \in \mathfrak{a}^n$ such that $ab \in \mathfrak{a}^m \cdot \mathfrak{a}^n = \mathfrak{a}^{m+n}$. In particular $\mathrm{ord}(ab) \geq m+n = \mathrm{ord}(a) + \mathrm{ord}(b)$. We may assume $m \leq n$, else interchange a and b. Then $\mathfrak{a}^n \subseteq \mathfrak{a}^m$ such that both, a and $b \in \mathfrak{a}^m$. In particular $a+b \in \mathfrak{a}^m$ such that $\mathrm{ord}(a+b) \geq m = \min\{\,\mathrm{ord}(a), \mathrm{ord}(b)\,\}$.

(7.42) Remark: (viz. 788)

Let $(R,+,\cdot)$ be a commutative ring and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be filter-ideal. Note that for any ideal $(\mathfrak{a},+)$ is a subgroup of the additive group $(R,+)$ of R. And thereby (6.41) tells us, that we get a metric d on R by taking $d(a,b) := 0$ for $a = b$ and for $a \neq b$ we have to define

$$d(a,b) \;:=\; \frac{1}{2^n} \quad \text{where} \quad n \;:=\; \mathrm{ord}(a-b)$$

In case of doubt we also write $d_{\mathfrak{a}}(a,b)$ for this metric. Recall that being a metric includes the symmetry and triangle inequality. That is for any a, b and $c \in R$ we get

(1) $d(a,b) \;=\; d(b,a)$

(2) $d(a,c) \;\leq\; d(a,b) + d(b,c)$

As always $(R,+)$ becomes a topological group, but in this case $(R,+,\cdot)$ even is a *topological ring*, that is $R\times R\to R:(a,b)\mapsto ab$ is continuous, too. In this so called $\mathfrak{a}$-*adic* topology on R, a set $U\subseteq R$ is said to be *open*, iff it satisfies the following property

$$U\subseteq R \text{ open} \iff \forall\, u\in U\ \exists\, n\in\mathbb{N}\ :\ u+\mathfrak{a}^n\subseteq U$$

Nota that the multiplication $(a,b)\mapsto ab$ of R is continuous can be translated in the following way: For any open set $W\subseteq R$ and any $a,b\in R$ with $ab\in W$ there are some open neighbourhoods $U\in\mathcal{T}(a)$ and $V\in\mathcal{T}(b)$ such that for any $u\in U$ and any $v\in V$ we have $uv\in W$ again.

(7.43) Definition:
Let $(R,+,\cdot)$ be a commutative ring and $\mathfrak{a}\trianglelefteq_{\mathfrak{i}} R$ be an ideal of R. Note that for any $n\in\mathbb{N}$ the quotient $\mathfrak{a}^n/\mathfrak{a}^{n+1}$ becomes an $R/\mathfrak{a}$-module under the scalar multiplication $(a+\mathfrak{a})(f+\mathfrak{a}^{n+1}):=(af+\mathfrak{a}^{n+1})$ which is well-defined. Let us now take to the exterior direct sum of these $R/\mathfrak{a}$-modules

$$R(\mathfrak{a}) \ :=\ \bigoplus_{n\in\mathbb{N}} \mathfrak{a}^n\Big/\mathfrak{a}^{n+1}$$

Therefore $R(\mathfrak{a})$ can be turned into an $R/\mathfrak{a}$-algebra (the so called *Rees-algebra* of R in $\mathfrak{a}$), by defining the following scalar multiplication and multiplication

$$\begin{aligned}(a+\mathfrak{a})\left(f_n+\mathfrak{a}^{n+1}\right) &:= \left(af_n+\mathfrak{a}^{n+1}\right)\\ \left(f_n+\mathfrak{a}^{n+1}\right)\left(g_n+\mathfrak{a}^{n+1}\right) &:= \left(\sum_{i+j=n} f_ig_j+\mathfrak{a}^{n+1}\right)\end{aligned}$$

Let us denote $R(\mathfrak{a})_n:=\mathfrak{a}^n/\mathfrak{a}^{n+1}$ where we consider $R(\mathfrak{a})_n$ to be a subset $R(\mathfrak{a})_n\subseteq R(\mathfrak{a})$ canonically (as in (3.30)). We take $R(\mathfrak{a})_n$ to be the *homogeneous* elements of $R(\mathfrak{a})$ of *degree* n. That is we let

$$\big(R(\mathfrak{a})\big)_{\text{hom}} \ :=\ \bigcup_{n\in\mathbb{N}} R(\mathfrak{a})_n\setminus\{0\}$$

Then the Rees-algebra becomes an $\mathbb{N}$-graded $R/\mathfrak{a}$-algebra $(R(\mathfrak{a}),\deg)$ under the following graduation

$$\deg\ :\ \big(R(\mathfrak{a})\big)_{\text{hom}}\to\mathbb{N}\ :\ f_n+\mathfrak{a}^{n+1}\mapsto n$$

Now, if the $\mathfrak{a}$ is a filter-ideal of R and $a\in R$ is a non-zero $a\neq 0$ element of R of order $m:=\operatorname{ord}(a)$, then we can define the **leading form** a^* of a to be the following homogeneous element of degree n. Specifically for $0\in R$ we let $0^*:=(0+\mathfrak{a}^n)\in R(\mathfrak{a})$.

$$a^* \ :=\ \left(a_n+\mathfrak{a}^{n+1}\right) \quad\text{where}\quad a_n\ :=\ \begin{cases} a \text{ if } n=m\\ 0 \text{ if } n\neq m\end{cases}$$

Nota It is obvious that this construction of $R(\mathfrak{a})$ yields an $R/\mathfrak{a}$-module. The next remark (7.44) tells us that $R(\mathfrak{a})$ also is the image of an R-algebra and thereby $R(\mathfrak{a})$ is an R-algebra itself. Together this means that $R(\mathfrak{a})$ is an $R/\mathfrak{a}$-algebra under $(a+\mathfrak{a})(f+\mathfrak{a}^{n+1})=(af+\mathfrak{a}^{n+1})$.

(7.44) Remark: (viz. 788)
Let $(R,+,\cdot)$ be a commutative ring and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be an ideal of R, then there is an alternate construction of the Rees-algebra: First of all the following set is a sub-algebra of the polynomial ring

$$R_{\mathfrak{a}}[t] \;:=\; \{\, f \in R[t] \mid \forall\, n \in \mathbb{N} : f[n] \in \mathfrak{a}^n \,\}$$

And thereby we find a surjective homomorphism of R algebras from $R_{\mathfrak{a}}[t]$ onto the Rees-algebra $R(\mathfrak{a})$, which is given to be

$$\varrho \;:\; R_{\mathfrak{a}}[t] \twoheadrightarrow R(\mathfrak{a}) \;:\; f \mapsto \left(f[n] + \mathfrak{a}^{n+1}\right)$$

Then the canonical embedding $R \hookrightarrow R[t] : a \mapsto a\mathbf{1}$ takes $\mathfrak{a}$ into $R_{\mathfrak{a}}[t]$. Then the ideal generated by $\{\, a\mathbf{1} \mid a \in \mathfrak{a} \,\} \subseteq R_{\mathfrak{a}}[t]$ is precisely the kernel of this homomorphism

$$\mathrm{kn}(\varrho) \;=\; \mathfrak{a}R_{\mathfrak{a}}[t] \;=\; \left\{\, f \in R[t] \mid \forall\, n \in \mathbb{N} : f[n] \in \mathfrak{a}^{n+} \,\right\}$$

(7.45) Definition:
Let $(D,+)$ and $(E,+)$ be commutative monoids, $(R,+,\cdot)$ be a commutative ring, $(A,\deg)$ be a D-graded and $(B,\deg)$ be an E-graded R-algebra. Then the ordered pair (φ,ε) is said to be a **homomorphism** of **graded algebras** from $(A,\deg)$ to $(B,\deg)$ (or shortly a *graded homomorphism*) iff it satisfies

(1) $\varphi : A \to B$ is a homomorphism of R-algebras

(2) $\varepsilon : D \to E$ is a homomorphism of monoids

(3) $\forall\, h \in A_{\mathrm{hom}}$ we get $\varphi(h) \in B_{\mathrm{hom}}$ and $\deg(\varphi(h)) = \varepsilon(\deg(h))$

If both $(A,\deg)$ and $(B,\deg)$ are D-graded R-algebras, then a homomorphism $\varphi : A \to B$ of R-algebras is said to be **graded** iff $(\varphi,\mathbb{1})$ is a homomorphism of graded algebras, that is iff it satisfies

(1) $\varphi : A \to B$ is a homomorphism of R-algebras

(2) $\forall\, h \in A_{\mathrm{hom}}$ we get $\varphi(h) \in B_{\mathrm{hom}}$

(3) $\forall\, h \in A_{\mathrm{hom}}$ we get $\deg(\varphi(h)) = \deg(h)$

(7.46) Definition: (viz. 783)
Let $(D,+)$ be a commutative monoid, $(R,+,\cdot)$ be a commutative ring and $(A,\deg)$ be a D-graded R-algebra. Then a subset $\mathfrak{h} \subseteq A$ is said to be a **graded ideal** (or *homogeneous ideal*) of $(A,\deg)$, iff $\mathfrak{h} \trianglelefteq_{\mathrm{i}} A$ is an ideal, that satisfies any one of the following three equivalent properties

(a) $\mathfrak{h}$ can be decomposed as the inner direct sum of its R-sub-modules $\mathfrak{h} \cap A_d \leq_{\mathrm{m}} \mathfrak{h}$, that is

$$\mathfrak{h} \;=\; \bigoplus_{d \in D} \mathfrak{h} \cap A_d$$

(b) $\mathfrak{h}$ is closed under going to homogeneous components. That is if $f \in \mathfrak{h}$ is decomposed into homogeneous elements $f = \sum_d f_d$, any homogeneous component $f_d \in A_d$ is an element of $\mathfrak{h}$

$$f = \sum_{d \in D} f_d \in \mathfrak{h} \quad\Longrightarrow\quad \forall\, d \in D : f_d \in \mathfrak{h}$$

(c) $\mathfrak{h}$ is generated (as an ideal) by a set H of homogeneous elements of A, in formal terms that is

$$\exists\, H \subseteq A_{\mathsf{hom}} \quad \text{such that} \quad \mathfrak{h} = \langle H \rangle_{\mathsf{i}}$$

(7.47) Remark:
If $(A, \deg)$ is a D-graded R-algebra and $\mathfrak{a} \trianglelefteq_{\mathsf{i}} A$ is a graded ideal of $(A, \deg)$, then it is clear, that $(\mathfrak{a}, \deg)$ becomes a D-graded R-semi-algebra under the graduation inherited from $(A, \deg)$

$$\begin{aligned} \mathfrak{a}_{\mathsf{hom}} &:= A_{\mathsf{hom}} \cap \mathfrak{a} \\ \deg &:= \deg\big|_{\mathsf{hom}(\mathfrak{a})} \end{aligned}$$

(7.48) Proposition: (viz. 785)
Let $(D, +)$ be a commutative monoid (with neutral element 0), $(R, +, \cdot)$ be a commutative ring and $(A, \deg)$ be a D-graded R-algebra. Then the following statements are true

(i) If D is an integral monoid, then $1 \in A_0$

(ii) If $(B, \deg)$ is another D-graded R-algebra and $\varphi : A \to B$ is a graded homomorphism, then the kernel of φ is a graded ideal in A, therefore we get

$$\mathsf{kn}(\varphi) = \bigoplus_{d \in D} \mathsf{kn}(\varphi) \cap A_d$$

(iii) If $\mathfrak{a} \trianglelefteq_{\mathsf{i}} A$ is a graded ideal of $(A, \deg)$, then the quotient $A/\mathfrak{a}$ becomes a D-graded R-algebra again under the induced graduation $\deg(h + \mathfrak{a}) := \deg(h)$. The homogeneous elements of $A/\mathfrak{a}$ are

$$\left(A \Big/ \mathfrak{a}\right)_{\mathsf{hom}} := \{\, h + \mathfrak{a} \mid h \in A_{\mathsf{hom}} \setminus \mathfrak{a} \,\}$$

And thereby the set of homogeneous elements of degree $d \in D$ is precisely given to be the following

$$\left(A \Big/ \mathfrak{a}\right)_d = A_d + \mathfrak{a} \Big/ \mathfrak{a}$$

(iv) Let $(D, +)$ even be a commutative group and consider a multiplicatively closed subset $U \subseteq A_{\mathsf{hom}}$. Then the localization $U^{-1}A$ (as a ring) is a D-graded R-algebra again. Thereby

$$\left(U^{-1}A\right)_{\mathsf{hom}} := \left\{ \frac{h}{u} \;\middle|\; h \in A_{\mathsf{hom}},\ u \in U \right\} \setminus \left\{ \frac{0}{1} \right\}$$

Then the graduation is defined to be $\deg(h/u) := \deg(h) - \deg(u)$ and the R-sub-module of $U^{-1}R$ of homogeneous elements of any degree $d \in D$ is given to be

$$\left(U^{-1}A\right)_d = \left\{ \frac{h}{u} \;\middle|\; u \in U,\ h \in A_{d+\deg(u)} \right\}$$

(v) Suppose $D = \mathbb{N}$ and consider some ideal $\mathfrak{a} \trianglelefteq_{\mathsf{i}} A$. If now $\mathfrak{a}$ is a graded ideal, then its radical $\sqrt{\mathfrak{a}} \trianglelefteq_{\mathsf{i}} A$ is a graded ideal, too.

(7.49) Remark:
The above statement (iv) has an easy generalization to the case where $(D,+)$ only is an integral, commutative monoid. In this case $U^{-1}A$ becomes a $\mathrm{gr}(D)$-graded R-algebra, where $\mathrm{gr}(D)$ denotes the extension of D to a group, as thereby $\deg(h/u) := \deg(h) - \deg(u) = [\deg(h), \deg(u)]$ is a legit operation in gr (D), again.
Formally that is $\mathrm{gr}(D) := (D \times D)/\sim$ where $(c,d) \sim (c',d') \;:\Longleftrightarrow\; c + d' = c' + d$. Then $\mathrm{gr}(D)$ becomes a well-defined group under $[c,d] + [c',d'] := [c+c', d+d']$ with neutral element $[0,0]$ and $-[c,d] = [d,c]$. And D is included canonically into grD by virtue of $D \hookrightarrow \mathrm{gr}(D) : c \mapsto [c,0]$.

(7.50) Definition:
Let $(R,+,\cdot)$ be a commutative ring, $(D,+,\leq)$ be a positively ordered monoid and $(A,\deg)$ be a D-graded R-algebra. If now $f \in A$ with $f \neq 0$ has the homogeneous decomposition $f = \sum_d f_d$ (where $f_d \in A_d$) then we define

$$\begin{aligned} \deg(f) &:= \max\{\, d \in D \mid f_d \neq 0 \,\} \\ \mathrm{ord}(f) &:= \min\{\, d \in D \mid f_d \neq 0 \,\} \end{aligned}$$

Nota this is well-defined, as only finitely many f_d are non-zero and $\leq$ is a linear order on D. And thus we have defined two functions $\deg : A \setminus \{0\} \to D$ and $\mathrm{ord} : A \setminus \{0\} \to D$ on A.

(7.51) Proposition: (viz. 789)
Let $(R,+,\cdot)$ be a commutative ring, $(D,+,\leq)$ be a positively ordered monoid and $(A,\deg)$ be a D-graded R-algebra. Then the following statements are true

(i) The newly introduced function $\deg : A \setminus \{0\} \to D$ is an extension of the original degree function $\deg : A_{\mathrm{hom}} \to D$. Formally that is

$$h \in A_d,\ h \neq 0 \quad\Longrightarrow\quad \deg(h) = d$$

(ii) It is clear that the *order* and *degree* of some homogeneous element $h \in A_{\mathrm{hom}}$ will agree. But even the converse is true, that is for any non-zero element $f \in \setminus\{0\}$ we get the equivalence

$$f \in A_{\mathrm{hom}} \quad\Longleftrightarrow\quad \mathrm{ord}(f) = \deg(f)$$

(iii) For any elements $f,\ g \in A$ such that $fg \neq 0$ the degree is sub-multiplicative and the order is super-multiplicative. That is we obtain the estimates

$$\begin{aligned} \mathrm{ord}(f) &\leq \deg(f) \\ \deg(fg) &\leq \deg(f) + \deg(g) \\ \mathrm{ord}(fg) &\geq \mathrm{ord}(f) + \mathrm{ord}(g) \end{aligned}$$

(iv) And if $(D, +, \leq)$ is a strictly positively ordered monoid and A is an integral domain, then for any $f, g \in A \setminus \{0\}$ we even get the equalities

$$\begin{aligned} \deg(fg) &= \deg(f) + \deg(g) \\ \operatorname{ord}(fg) &= \operatorname{ord}(f) + \operatorname{ord}(g) \end{aligned}$$

(v) Thus if $(D, +, \leq)$ is a strictly positively ordered monoid and $A \neq 0$ is a non-zero integral domain again, then the invertible elements of A already are homogeneous

$$A^* \subseteq A_{\mathsf{hom}}$$

(vi) If $(D, +, \leq)$ is a strictly positively ordered monoid, A is an integral domain and $h \in A_{\mathsf{hom}}$ is a homogeneous element of A, then any divisor f of h also is a homogeneous element of A, formally

$$f \mid h \implies f \in A_{\mathsf{hom}}$$

7.5 Polynomial Functions

In this section we will be primarily concerned with functions of polynomials f in one variable over a commutative ring R, more specifically with roots of these functions. In case of one variable the sets of solutions of equations of the form $f(x) = 0$, where $f \in R[t]$ is a polynomial, are finite collections of points $x \in R$ only - at least so, if R is an integral domain and $f \neq 0$. In general (with 2 or more variables) this is untrue, e.g. $s - t \in R[s,t]$ already has the solutions (x,x) where $x \in R$. As this is the diagonal in the plane R^2 we already see, that the set of roots of a polynomial in several variables is a geometric object. That is, looking at polynomials, we are able to study both algebra and geometry simultaneously. Yet as $R[s,t]$ is just another version of $R[s][t]$ the restriction to one variable is no restriction at all, for general commutative rings R. It *is* a restriction, when we require the base ring R to be a field, though. Some of the following theorems are veritable cornerstones of algebra and some have direct impact on general polynomial rings $R[t_1,\ldots,t_n]$. As polynomials mimic generic algebraic operations they are the prototype of any algebra. And it is precisely the method of evaluating a polynomial on elements of an R-algebra, that transfers the algebraic operations back into the algebra. This is what makes polynomials so universally useful.

(7.52) Definition:
Let $(R,+,\cdot)$ be a commutative ring and fix any non-empty set $I \neq \emptyset$. Let us also abbreviate the polynomial ring the R-algebra $A := R[t_i \mid i \in I]$ in the variables t_i where i runs over I. That is $A = R[t \mid \mathbb{N}^{\oplus I}]$ is the R-algebra of polynomials over the commutative, integral and solution-finite monoid $\mathbb{N}^{\oplus I}$. No matter what size I has, by definition any $\alpha \in \mathbb{N}^{\oplus I}$ only has finitely many non-zero entries, that is $I(\alpha) := \{\, i \in I \mid \alpha_i \neq 0 \,\}$ is finite. Therefore for *any* I-tuple $x = (x_i) \in R^I$ and any $\alpha = (\alpha_i) \in \mathbb{N}^{\oplus I}$ the following expression yields a well-defined element of R

$$x^\alpha \;:=\; \prod_{i\in I} x_i^{\alpha_i} \;=\; \prod_{i\in I(\alpha)} x_i^{\alpha_i}$$

as the infinite product for $i \in I$ in truth only is a finite product $i \in I(\alpha)$, all the $i \in I \setminus I(\alpha)$ only contribute $x_i^0 = 1$. Likewise for a polynomial $f \in A$ we have required that the set $A(f) := \{\, \alpha \in \mathbb{N}^{\oplus I} \mid f[\alpha] \neq 0 \,\}$ is finite, too. Thus the following expression yields another well-defined element of R

$$f(x) \;:=\; \sum_{\alpha\in\mathbb{N}^{\oplus I}} f[\alpha]\, x^\alpha \;:=\; \sum_{\alpha\in A(f)} f[\alpha]\, x^\alpha$$

Again the seemingly infinite sum over $\alpha \in \mathbb{N}^{\oplus I}$ only runs over the finite subset $A(f)$, all the other $\alpha \in \mathbb{N}^{\oplus I} \setminus A(f)$ only contribute $0 \cdot x^\alpha = 0$. So in the end we find a map of the following form

$$A \times R^I \;\to\; R \;:\; (f,x) \;\mapsto\; f(x)$$

Note that both, $A = R[t_i \mid i \in I]$ and the set of functions $\mathcal{F}(R^I,R) := \{\, f \mid f : R^I \to R \,\}$ are R-algebras. The operations on A have been defined in (7.10.(i)) and the operations on $\mathcal{F}(R^I,R)$ are the point-wise operations $(af)(x) = af(x)$, $(f+g)(x) = f(x) + g(x)$ and $(f\cdot g)(x) = f(x)\cdot g(x)$ respectively.

There's two different ways of turning the above map into a homomorphism of R-algebras: By construction, for any $x \in R^I$ the map $\mathbb{N}^{\oplus I} \to R : \alpha \mapsto x^\alpha$ is a homomorphism of monoids and thereby (7.14) tells us that the following map is a well-defined homomorphism of R-algebras

$$\varepsilon_x \ : \ A \ \to \ R \ : \ f \ \mapsto \ f(x)$$

Thus we have a map $\varepsilon : R^I \to \text{ahom}(A, R) : x \mapsto \varepsilon_x$. This map however does not carry any algebraic structure. On the other hand we can interpret the above map in the following form

$$P \ : \ A \ \to \ \mathcal{F}(R^I, R) \ : \ f \mapsto P_f$$

where $P_f : R^I \to R : x \mapsto f(x)$. This assignment P even is a homomorphism of R-algebras, as $\mathcal{F}(R^I, R)$ is equipped with the pointwise operations. The function P_f is said to be the **polynomial function** induced by $f \in A$. Again it does not carry any algebraic structure. And (by slight abuse of notation) we denote the set of **roots** of P_f by $\mathbb{V}(f)$ again

$$\mathbb{V}(f) \ := \ \mathbb{V}(P_f) \ = \ \left\{ x \in R^I \ \middle| \ f(x) = 0 \right\}$$

(7.53) Remark: $(\diamondsuit)$
This even holds true if $S : R$ is a ring extension and $x = (x_i) \in S^I$. In this case we get $f(x) \in S$ again. That is P_f is a function of the form $P_f : S^n \to S$ and thereby we obtain an homomorphism of R-algebras

$$P \ : \ R[t_i \mid i \in I] \ \to \ \mathcal{F}(S^n, S) \ : \ f \ \mapsto \ P_f$$

As the operations on $\mathcal{F}(S^n, S)$ are point-wise and $P_f(x) = f(x)$ this is to say, that for any $a \in R$, f, $g \in R[t_i \mid i \in I]$ and $x \in S^I$ we have the identities $(af)(x) = af(x)$, $(f+g)(x) = f(x) + g(x)$ and $(f \cdot g)(x) = f(x) \cdot g(x)$. The set of roots of f thereby is a subset of S^I

$$\mathbb{V}_S(f) \ := \ \left\{ x \in S^I \ \middle| \ f(x) = 0 \right\} \ \subseteq \ S^I$$

(7.54) Lemma: (viz. 795)
Let $(R, +, \cdot)$ be a non-zero, commutative ring consider a polynomial $f \in R[t]$ in one variable over R. Let $n := \deg(f)$ be the degree of f, where $\leq$ is the standard total order on $\mathbb{N}$. Then we get

(i) If $a \in R$ is any element of the base ring, $n \in \mathbb{N}$ is any natural number and $g(t) := f(t) \cdot (t - a) \in R[t]$, then we obtain the equivalence of the following two statements

 (a) g is a monic polynomial of degree n

 (b) f is a monic polynomial of degree $n - 1$

(ii) If $f \in R[t]$ is any polynomial over R and $a \in R$ any element of the base ring, then there is another polynomial $q \in R[t]$, such that f can be written in the following form

$$f(t) \ = \ q(t) \cdot (t - a) + f(a)$$

(iii) For any polynomial $f \in R[t]$ and any $a \in R$ we find, that the evaluation $f(a) = 0$ is zero, if and only if the polynomial $t - a$ divides f in $R[t]$. Formally this is the equivalence

$$f(a) \;=\; 0 \quad\Longleftrightarrow\quad (t-a) \;\mid\; f(t)$$

(iv) If R is an integral domain and $x_1, \ldots, x_m$ are pairwise distinct roots of f [that is for all $i, j \in 1 \ldots m$ we have $f(x_i) = 0$ and $x_i = x_j \implies i = j$] then there is some polynomial $q \in R[t]$ such that

$$f(t) \;=\; (t - x_1) \ldots (t - x_m)\, q(t)$$

In particular, if R is an integral domain and $f \neq 0$ is non-zero, then the number of distinct roots of f cannot exceed the degree of f. In formal terms that is

$$\#\{\, x \in R \mid f(x) = 0 \,\} \;\leq\; \deg(f)$$

(v) If R is an integral domain and $f, g \in R[t]$ are polynomials, whose number of intersection points exceed their degrees, then f and g already are equal. Formally that is

$$\max\{\, \deg(f), \deg(g) \,\} \;<\; \#\{\, x \in R \mid f(x) = g(x) \,\} \quad\Longrightarrow\quad f \;=\; g$$

(7.55) Example:
If R is not an integral domain, then the equation $f(x) = 0$, where $f \in R[t]$ can have more solutions, than $n = \deg(f)$. As an example consider $R = \mathbb{Z}_8$ and $f(t) := t^2 - 1$. In this case $f(x) = 0$ boasts 4 different solutions, namely

$$\{\, x \in \mathbb{Z}_8 \mid x^2 - 1 \,\} \;=\; \{\, 1, 3, 5, 7 \,\}$$

This example also shows, that (in a non-integral domain) $x^2 = 1$ can have more solutions than the classical 1 and -1. And in fact these roots give rise to two distinct factorisations of f, namely

$$t^2 - 1 \;=\; (t-1)(t-7) \;=\; (t-3)(t-5)$$

(7.56) Example: (viz. 797)
Let $(R, +, \cdot)$ be a commutative ring, $1 \leq n \in \mathbb{N}$ and let us abbreviate $S := R[t_1, \ldots, t_n]$ and the n-tuple $t := (t_1, \ldots, t_n) \in S^n$. If now $A = (a_{i,j}) \in \mathrm{mat}_n(R)$ is a square matrix, then we define the following R-algebra-endomorphism on S, by linear expansion of

$$\varphi_A \;:\; S \to S \;:\; t_i \mapsto [At]_i \;=\; \sum_{j=1}^{n} a_{i,j} t_j$$

That is φ_A is the uniquely determined R-algebra-homomorphism, that satisfies $\varphi_A(t_i) = [At]_i$ which exists by (7.14). Then we clearly have (i) if $E = \mathbb{1}_n$ is the identity matrix, then $\varphi_E = \mathbb{1}_S$ and (ii) if $B \in \mathrm{mat}_n(R)$ is any other $(n \times n)$-matrix, then $\varphi_B\, \varphi_A = \varphi_{AB}$. In particular (iii) if A is invertible, then φ_A is an R-algebra-automorphism of S with inverse $\varphi_{A^{-1}}$.

(7.57) Proposition: (viz. 798)
Let $(F,+,\cdot)$ be a field $1 \leq n \in \mathbb{N}$ and consider the polynomial ring in n variables $F[t_1,\ldots,t_n]$. Also let $f \in F[t_1,\ldots,t_n]$ be a non-zero polynomial $f \neq 0$. Let x_1 to x_n be the variable symbols of another polynomial ring $F[x_1,\ldots,x_n]$ and denote $R := F[x_2,\ldots,x_n]$. Then we find the following coordinate transforms to which f can be subjected

(i) If F is infinite (actually it suffices, that F is an infinite integral domain) and f is homogeneous, then there are some $a_2,\ldots,a_n \in F$ such that

$$f(1,a_2,\ldots,a_n) \quad \neq \quad 0 \quad \in \quad F$$

(ii) If F is infinite (and a field), then there are scalars $a \in F$ and $a_2,\ldots,a_n \in F$ such that the following polynomial in the variables x_1 to x_n is monic, if written as a polynomial in x_1 over R:

$$af\big(x_1, x_2 + a_2x_1, \ldots, x_n + a_nx_1\big) \quad \in \quad R[x_1]$$

(iii) For any field F there are some $a \in F$ and numbers $1 \leq m_2,\ldots,m_n \in \mathbb{N}$ such that the following polynomial in the variables x_1 to x_n is monic, if written as a polynomial in x_1 over R:

$$af\big(x_1, x_2 + x_1^{m_2}, \ldots, x_n + x_1^{m_n}\big) \quad \in \quad R[x_1]$$

(7.58) Remark: (viz. 799) **Interpolation**
Consider an integral domain $(R,+,\cdot)$ and some points $(x_i,y_i) \in R^2$ in the plane of R, where $1 \leq n \in \mathbb{N}$. To avoid redundancies or contradictions we have to assume that the x_i are pairwise distinct [i.e. $x_i = x_j$ implies $i = j$]. We are looking for a polynomial $f \in R[t]$ that satisfies $f(x_i) = y_i$ for any $i \in 1\ldots n$. As we have n unknown $y_1,\ldots,y_n \in R$ it stands to reason to also regard n variables - the coefficients of f

$$f(t) \quad = \quad f[n-1]t^{n-1} + \cdots + f[1]t + f[0]$$

(i) *Brute Force*: The set $\mathcal{P}_n := \{\, f \in R[t] \mid \deg(f) < n \,\}$ is a free R-module of dimension n, as a basis is given to be $\{\, \mathbf{1}, t, \ldots, t^{n-1} \,\}$. If we write out $f(x_i) = y_i$ we arrive at $f[n-1]x_i^{n-1} + \cdots + f[1]x_i + f[0] = y_i$. As this shall be true for any $i \in 1\ldots n$ we arrive at an $n \times n$-system of linear equations

$$\begin{pmatrix} 1 & x_1 & \cdots & x_1^{n-1} \\ 1 & x_2 & \cdots & x_2^{n-1} \\ \vdots & \vdots & & \vdots \\ 1 & x_n & \cdots & x_n^{n-1} \end{pmatrix} \begin{pmatrix} f[0] \\ f[1] \\ \vdots \\ f[n-1] \end{pmatrix} = \begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix}$$

The $n \times n$-matrix occurring in this system is called the *Vandermonde* matrix of the x_i, denoted by $\mathrm{Van}(x_1,\ldots,x_n)$. By Laplace-expansion of the determinant we find that the determinant of this matrix is given to be the product of the $x_j - x_i$ where $i < j$:

$$\det\Big(\mathrm{Van}(x_1,\ldots,x_n)\Big) \quad = \quad \prod_{1 \leq i < j \leq n} (x_j - x_i)$$

Hence, if this determinant is a unit of R, we may compute the coefficients of f by solving this

system of linear equations. In effect we get: If the determinant of the Vandermonde matrix of the x_i, is a unit of R, then there is a uniquely determined polynomial f of degree $\deg(f) < n$ such that $f(x_i) = y_i$ for all $i \in 1 \ldots n$. While this is feasible in theory this approach is rarely used for practical computations, as solving this system takes too much effort.

(ii) *Lagrange Interpolation*: We use that $\mathcal{P}_n := \{ f \in R[t] \mid \deg(f) < n \}$ is a free R-module of dimension n again, but this time we choose a more suitable basis: For a fixed $j \in 1 \ldots n$ let

$$\ell_j(t) \;:=\; \prod_{i \neq j} (t - x_i)$$

which is a polynomial of degree $n-1$ over R. Let $u_j := \ell_j(x_j)$ and suppose that all the $u_j \in R^*$ are invertible. Then we may introduce the following polynomials

$$L_j(t) \;:=\; u_j^{-1}\, \ell_j(t) \;=\; \prod_{i \neq j} \frac{t - x_i}{x_j - x_i}$$

Then by construction we have $L_j(x_i) = \delta_{i,j}$ and hence $\{ L_1, \ldots, L_n \} \subseteq \mathcal{P}_n$ is a linearly independent subset, even a basis of $\mathcal{P}_n$. And we obtain a polynomial $f \in \mathcal{P}_n$ such that $f(x_i) = y_i$ (for any $i \in 1 \ldots n$) simply by taking

$$f(t) \;:=\; \sum_{i=1}^{n} y_i\, L_i(t)$$

(iii) *Newtonian Interpolation*: Lies somewhere in between the brute force approach and the approach of Lagrange. Again we try to find $f \in \mathcal{P}_n$ as a linear combination of certain polynomials $N_j \in \mathcal{P}_n$

$$f(t) \;=\; \sum_{j=0}^{n-1} a_j\, N_j(t)$$

However in this case we start with $N_0(t) := \mathbf{1}$ and for $j \in 1 \ldots n-1$ we recursively define N_j by

$$N_j(t) \;:=\; N_{j-1}(t) \cdot (t - x_j) \;=\; \prod_{i=1}^{j} (t - x_i)$$

In particular we have $\deg(N_j) = j$ and thereby $N_j \in \mathcal{P}_n$. Also for any $i \in 1 \ldots j$ we see that $N_j(x_i) = 0$ by construction. Hence for any $i \in 1 \ldots n$ the equation $f(x_i) = y_i$ is reduced to the sum of $a_j N_j(x_i)$ where $j < i < n$. In the language of matrices that is

$$\begin{pmatrix} 1 & 0 & 0 & \cdots & 0 \\ 1 & N_1(x_2) & 0 & \cdots & 0 \\ 1 & N_1(x_3) & N_2(x_3) & & \\ \vdots & \vdots & \vdots & \ddots & \\ 1 & N_1(x_n) & N_2(x_n) & \cdots & N_{n-1}(x_n) \end{pmatrix} \begin{pmatrix} a_0 \\ a_1 \\ \vdots \\ a_{n-1} \end{pmatrix} \;=\; \begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix}$$

This SLE can be solved if for any $i \in 2 \dots n$ we have $N_{i-1}(x_i) \in R^*$ is a unit. Thereby the product of the $N_{i-1}(x_i)$ is the determinant of the Vandermonde matrix, hence this again is equivalent to the determinant being invertible. The advantage of this approach is (1) this SLE is easy to solve, (2) the polynomials $N_j(t)$ can be computed recursively and (3) it is easy to append another point (x_{n+1}, y_{n+1}) by just adding another row to the matrix. This makes this method the preferred algorithm for interpolation in numerical applications.

(7.59) Corollary: (viz. 801)

(i) Let $(F, +, \cdot)$ be a field, $1 \leq n \in \mathbb{N}$ and consider $(x_i, y_i) \in F^2$ such that $x_i = x_j$ implies $i = j$. Then there is a uniquely determined polynomial $f \in F[t]$ that satisfies the following two properties

(1) $\deg(f) < n$

(2) $\forall\, i \in 1 \dots n$ we get $f(x_i) = y_i$

(ii) Let $(F, +, \cdot)$ be a field and consider the map $P : F[t] \to \mathcal{F}(F, F)$ given by $P : f \mapsto P_f$ where $P_f : F \to F : x \mapsto f(x)$. If F is finite then P is surjective, but not injective. And if F is infinite then P is injective but not surjective. Formally

$$\begin{aligned} \#F &< \infty \iff f \mapsto P_f \text{ is surjective} \\ \#F &= \infty \iff f \mapsto P_f \text{ is injective} \end{aligned}$$

Algebraic Sets:
So far for polynomials in one variable only. Let us take a very short glance behind the curtain: Algebraic Geometry studies the set of roots of a polynomial in severable variables in case the base ring R is an algebraically closed field. Though this would be a course of its own, let us introduce the basic notions here, up to the Zariski-topology on the space R^I:
So what is a root, anyway? Recall that if $f \in R[t_i \mid i \in I]$ is a polynomial over a commutative ring R and S is a commutative R-algebra and $x = (x_i) \in S^I$ is a point we have defined in (7.52)

$$f(x) \;:=\; \sum_{\alpha \in \mathbb{N}^{\oplus I}} f[\alpha] \prod_{i \in I} x_i^{\alpha_i}$$

And thereby $R[t_i \mid i \in I] \to S : f \mapsto f(x)$ is a homomorphism of R-algebras according to (7.14). If $f(x) = 0$ we say that x is a **root** of f or equivalently that x **satisfies** f. So where's the geometry? Here it is: E.g. in three dimensional space, the following equation defines a sphere of radius r around the centre $C = (c_1, c_2, c_3) \in R^3$

$$f(t_1, t_2, t_3) \;:=\; (t_1 - c_1)^2 + (t_2 - c_2)^2 + (t_3 - c_3)^2 - r^2$$

The set of $x \in R^3$ that satisfy f (that is $f(x) = 0$) geometrically has the shape of this sphere. Generally speaking geometric objects are sets of roots of functions and combinations thereof. In algebraic geometry these equations are taken to be polynomial and this already allows a multitude of objects.

So what do we mean by combinations thereof? If $X \subseteq S^I$ is defined by the equation $f \in R[t_i \mid i \in I]$ and likewise $Y \in R^I$ is defined by $g \in R[t_i \mid i \in I]$ then the intersection $X \cap Y$ is defined by $f(x) = 0$ *and* $g(x) = 0$. Likewise the union $X \cup Y$ is defined by $f(x) = 0$ *or* $g(x) = 0$. If S is an integral domain, this is $(f \cdot g)(x) = 0$. Here we already see that geometric operations correspond to algebraic compositions. Let us dig just a little deeper:

(7.60) Definition:
Let $(R, +, \cdot)$ be a commutative ring and fix any non-empty index set I. If $F \subseteq R[t_i \mid i \in I]$ respectively $X \subseteq R^I$ are arbitrary subsets, then we define the **algebraic set** to be the common zero-locus $\mathbb{V}(F)$ of the polynomials $f \in F$, respectively the **vanishing ideal** $\mathbb{I}(X)$ to be the set of polynomials that vanish on X identically. Formally that is

$$\begin{aligned} \mathbb{V}(F) &:= \left\{ x \in R^I \;\middle|\; \forall f \in F : f(x) = 0 \right\} \\ \mathbb{I}(X) &:= \{ f \in R[t_i \mid i \in I] \mid \forall x \in X : f(x) = 0 \} \end{aligned}$$

Nota If $f \in R[t_i \mid i \in I]$ is a single polynomial, then (by slight abuse of notation) we abbreviate $\mathbb{V}(f) := \mathbb{V}(\{ f \}) = \{ x \in R^I \mid f(x) = 0 \}$ the algebraic set of f. And likewise, for a single point $x \in R^I$ we abbreviate $\mathbb{I}(x) := \mathbb{I}(\{ x \}) = \{ f \in R[t_i \mid i \in I] \mid f(x) = 0 \}$ the vanishing ideal of x.

(7.61) Proposition: (viz. 802)
Let $(R, +, \cdot)$ be a commutative ring and fix any non-empty index set I. Then we find the following relations between the algebraic sets $\mathbb{V}(F)$ and vanishing ideals $\mathbb{I}(X)$:

(i) Let $f \in R[t_i \mid i \in I]$ be a polynomial and $X \subseteq R^I$ be an arbitrary subset. Then from the above definitions it is immediately clear, that we have the following equivalences

$$f \in \mathbb{I}(X) \iff X \subseteq \mathbb{V}(f) \iff \mathbb{V}\mathbb{I}(X) \subseteq \mathbb{V}(f)$$

Likewise, if $F \subseteq R[t_i \mid i \in I]$ is any family of polynomials over R and $x \in R^I$ is any point, then we similarly obtain the following equivalences

$$x \in \mathbb{V}(F) \iff F \subseteq \mathbb{I}(x) \iff \mathbb{I}\mathbb{V}(F) \subseteq \mathbb{I}(x)$$

(ii) Let $X \subseteq R^I$ be an arbitrary subset, then the vanishing ideal $\mathbb{I}(X)$ of X truly is an ideal of $R[t_i \mid i \in I]$. And if $\text{NIL}(R) = 0$, then $\mathbb{I}(X)$ even is a radical ideal. Formally that is

$$\sqrt{\mathbb{I}(X)} = \mathbb{I}(X) \trianglelefteq_{\mathrm{i}} R[t_i \mid i \in I]$$

(iii) Let $F \subseteq R[t_i \mid i \in I]$ be an arbitrary subset and let $\mathfrak{a} := \langle F \rangle_{\mathrm{i}}$ denote the ideal of $R[t_i \mid i \in I]$ generated by F. Then F defines the same algebraic set as $\mathfrak{a}$ itself (that is $\mathbb{V}(F) = \mathbb{V}(\mathfrak{a})$) and if $\text{NIL}(R) = 0$, then we even get

$$\mathbb{V}(F) = \mathbb{V}(\mathfrak{a}) = \mathbb{V}(\sqrt{\mathfrak{a}})$$

(iv) For the moment being let us denote $A := R[t_i \mid i \in I]$ the R-algebra of the polynomial ring and the power sets, its set of ideals $\mathrm{Ideal}(A) := \{\mathfrak{a} \mid \mathfrak{a} \trianglelefteq_{\mathrm{i}} A\}$ and the power set $\mathcal{P}(R^I) := \{X \mid X \subseteq R^I\}$ of R^I. Then we have the defined the functions

$$\begin{aligned} \mathbb{V} &: \mathrm{Ideal}(A) \to \mathcal{P}(R^n) &&: \mathfrak{a} \mapsto \mathbb{V}(\mathfrak{a}) \\ \mathbb{I} &: \mathcal{P}(R^n) \to \mathrm{Ideal}(A) &&: X \mapsto \mathbb{I}(X) \end{aligned}$$

Note that both, the power set $\mathcal{P}(R^I)$ and the set $\mathrm{Ideal}(A)$ of ideals, are partially ordered under the inclusion "$\subseteq$" of sets. Then we find that $\mathbb{V}$ and $\mathbb{I}$ form a *Galois connection* between these ordered sets. That is for any $X, Y \subseteq R^I$ and any $\mathfrak{a}, \mathfrak{b} \trianglelefteq_{\mathrm{i}} R[t_i \mid i \in I]$ we get

$$\begin{aligned} X \subseteq Y &\implies \mathbb{I}(X) \subseteq \mathbb{I}(Y) \\ \mathfrak{a} \subseteq \mathfrak{b} &\implies \mathbb{V}(\mathfrak{b}) \subseteq \mathbb{V}(\mathfrak{a}) \\ X &\subseteq \mathbb{V}\mathbb{I}(X) \\ \mathfrak{a} &\subseteq \mathbb{I}\mathbb{V}(\mathfrak{a}) \end{aligned}$$

In particular by (0.22) we have $\mathbb{V}\mathbb{I}\mathbb{V} = \mathbb{V}$ and $\mathbb{I}\mathbb{V}\mathbb{I} = \mathbb{I}$. And thereby $\mathbb{V}$ and $\mathbb{I}$ are bijective, mutually inverse maps when restricted to the respective images, that is a 1-to-1 correspondence

$$\begin{aligned} \mathbb{V}\big(\mathrm{Ideal}(A)\big) &\longleftrightarrow \mathbb{I}\big(\mathcal{P}(R^I)\big) \\ X &\mapsto \mathbb{I}(X) \\ \mathbb{V}(\mathfrak{a}) &\hookleftarrow \mathfrak{a} \end{aligned}$$

(v) Consider the non-empty index sets $\Lambda = 1 \ldots n$ or an arbitrary $\Lambda \neq \emptyset$ respectively. For any $\lambda \in \Lambda$ let $\mathfrak{a}_\lambda \trianglelefteq_{\mathrm{i}} R[t_i \mid i \in I]$ be an ideal. Then the respective algebraic sets satisfy the properties

$$\begin{aligned} \mathbb{V}(0) &= R^I \\ \mathbb{V}(\mathfrak{a}_1) \cup \cdots \cup \mathbb{V}(\mathfrak{a}_n) &\subseteq \mathbb{V}\big(\mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_n\big) \\ \mathbb{V}\big(\mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_n\big) &\subseteq \mathbb{V}\big(\mathfrak{a}_1 \cdot \ldots \cdot \mathfrak{a}_n\big) \\ \mathbb{V}\left(\sum_{\lambda\in\Lambda} \mathfrak{a}_\lambda\right) &= \bigcap_{\lambda\in\Lambda} \mathbb{V}(\mathfrak{a}_\lambda) \end{aligned}$$

And if R is an integral domain we even get $\mathbb{V}(\mathfrak{a}_1) \cup \cdots \cup \mathbb{V}(\mathfrak{a}_n) = \mathbb{V}(\mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_n) = \mathbb{V}(\mathfrak{a}_1 \cdot \ldots \cdot \mathfrak{a}_n)$. Conversely let $X_\lambda \subseteq R^I$ be arbitrary subsets of the I-dimensional space over R (where $\lambda \in \Lambda$), then we retain some of the dual properties of the above, that is we also have

$$\begin{aligned} \mathbb{I}(\emptyset) &= R[t_i \mid i \in I] \\ \bigcap_{\lambda\in\Lambda} \mathbb{I}(X_\lambda) &= \mathbb{I}\left(\bigcup_{i\in I} X_i\right) \\ \sum_{\lambda\in\Lambda} \mathbb{I}(X_\lambda) &\subseteq \mathbb{I}\left(\bigcap_{\lambda\in\Lambda} X_\lambda\right) \end{aligned}$$

(vi) If $R \neq 0$ is non-zero, then $\mathbb{V}(R[t_i \mid i \in I]) = \emptyset$. And if R is an infinite integral domain (i.e. $\#R = \infty$), then the vanishing ideal of the entire space R^I is the zero-ideal, formally

$$\mathbb{I}(R^I) \;=\; 0$$

(7.62) Remark: (viz. 804)
If $(R, +, \cdot)$ is an integral domain, then we have just seen, that the algebraic sets $\mathbb{V}(\mathfrak{a})$ are closed under finite unions and arbitrary intersections, as we have the identities

$$\begin{aligned} \mathbb{V}(\mathfrak{a}_1) \cup \cdots \cup \mathbb{V}(\mathfrak{a}_n) &= \mathbb{V}\big(\mathfrak{a}_1 \cdot \ldots \cdot \mathfrak{a}_n\big) \\ \bigcap_{i \in I} \mathbb{V}(\mathfrak{a}_i) &= \mathbb{V}\left(\sum_{i \in I} \mathfrak{a}_i\right) \end{aligned}$$

As also $\mathbb{V}(0) = R^n$ and $\mathbb{V}(R[t_i \mid i \in I]) = \emptyset$ the algebraic sets form the *closed* sets of a topology on R^I. This is called the *Zariski topology* of R^I and this is the staging area of algebraic geometry

$$\mathcal{Z}\big(R^I\big) \;:=\; \{\, \mathbb{V}(\mathfrak{a}) \mid \mathfrak{a} \trianglelefteq_{\mathrm{i}} R[t_1, \ldots, t_n] \,\}$$

Conversely let $\mathcal{I}(R^I) := \{\mathbb{I}(X) \mid X \subseteq R^I\}$ be the set of ideals of $R[t_i \mid i \in I]$ that occur as vanishing ideals of subsets $X \subseteq R^I$. Then we know by (7.61.(ii)), that $\mathcal{I}(R^I) \subseteq \mathrm{Srad}(R[t_i \mid i \in I])$. And by (7.61.(iv)) the Galois connection of $\mathbb{I}$ and $\mathbb{V}$ restricts to the following 1-to-1 correspondence

$$\begin{aligned} \mathcal{Z}\big(R^I\big) &\longleftrightarrow \mathcal{I}\big(R^I\big) \\ X &\mapsto \mathbb{I}(X) \\ \mathbb{V}(\mathfrak{a}) &\hookleftarrow \mathfrak{a} \end{aligned}$$

The question, whether any radical ideal of $R[t_i \mid i \in I]$ occurs as a vanishing ideal of some algebraic set will be answered by Hilbert's Nullstellensatz in section 8.5: This will only be the case, for algebraically closed fields R. Even for the field of real numbers $R = \mathbb{R}$, the maximal ideal $\mathfrak{z} := (t^2 + 1)\mathbb{R}[t]$ satisfies $\mathbb{V}(\mathfrak{z}) = \emptyset$ and hence $\mathfrak{z} \subset \mathbb{R}[t] = \mathbb{I}\mathbb{V}(\mathfrak{z})$. That is $\mathfrak{z}$ is not a vanishing ideal of an algebraic set. However for an integral domain we get

(i) For any subset $X \subseteq R^I$ the closure of X in the Zariski-topology is given to be $\overline{X} = \mathbb{V}\mathbb{I}(X)$.

(ii) If R infinite and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R[t_i \mid i \in I]$ is any ideal, then we have $\mathbb{V}(\mathfrak{a}) = R^I$ if and only if $\mathfrak{a} = 0$.

Symmetric Polynomials:
After this excursion into the set of roots of polynomials in arbitrarily many variables, let us return to the case of one variable only. This is not a real restriction, as we can shove off all but one variable down into the base ring, using the isomorphy of $R[t_1, \ldots, t_n]$ and $R[t_2, \ldots, t_n][t_1]$. So we still are interested in the roots of a polynomial in one variable, but this time we take take the back door: What if we knew all the roots, what can we say about its coefficients, then?

The answer to this question is provided by the theorem of Vieta. In order to formulate this we have to introduce symmetric polynomials, which are of interest in their own right. We begin with an example, that illustrates how the elementary symmetric polynomials emerge. After this we will formulate prove the theorem of Vieta - even though the polynomial in question has a single variable only, it has several roots. And as we represent any root by a variable, symmetric polynomials have finitely many variables, by nature. We conclude by studying symmetric polynomials in general.

(7.63) Example:
Consider any commutative ring R, e.g. $R = \mathbb{Z}$ and a monic polynomial $f \in R[t]$. We are interested in the *roots* of f, that is the solutions $x \in R$ to the equation $f(x) = 0$. As these can be very hard to find, let us first start the other way round: Suppose that f *splits* over R, that is there are some $x_1, \ldots, x_n \in R$ such that f can be written, as

$$f(t) \;=\; (t - x_1)(t - x_2) \ldots (t - x_n)$$

Then clearly for any $i \in 1 \ldots n$ we have $f(x_i) = 0$ and (if R is an integral domain), these also are the only solutions to $f(x) = 0$. So how do the roots build up the coefficients of f? In case $n = 1$ we see $f[1] = 1$ and $f[0] = -x_1$. This is not very instructive. In case $n = 2$ we compute

$$f(t) \;=\; t^2 - (x_1 + x_2)t + x_1x_2$$

That is $f[1]$ is the negative sum of the roots, whereas $f[0]$ is the product of the roots. Let us check, what happens in case $n = 3$, here we find

$$f(t) \;=\; t^3 - (x_1 + x_2 + x_3)t^2 + (x_1x_2 + x_1x_3 + x_2x_3)t - x_1x_2x_3$$

Again the second highest coefficient $f[2]$ is the negative sum of the roots, and the constant term $f[0]$ is the negative product of the roots - it seems we are after something (the theorem of Vieta). The middle coefficient $f[1]$ is a little weird, at first glance. But it a sum of pairs x_ix_j. No wonder: $f[k]$ is accompanied by t^k so we need to pick $n - k$ of the x_i from the brackets, when expanding the term of f. Thereby any combination of x_i is allowed, but of course we may not pick from the same bracket twice. This is the reasoning behind the definition of the elementary symmetric polynomials (see below) and the reason why the theorem of Vieta holds true.

(7.64) Definition:
For any $1 \leq n \in \mathbb{N}$ denote $S_n := \{\, \sigma : 1 \ldots n \to 1 \ldots n \mid \sigma \text{ is bijective} \,\}$ the set of permutations again. Also let $(R, +, \cdot)$ be any ring and $f \in R[t_1, \ldots, t_n]$ be a polynomial in n variables over R. If $\sigma \in S_n$ is any permutation, we denote

$$\sigma f \;:=\; f\big(t_{\sigma(1)}, \ldots, t_{\sigma(n)}\big) \;=\; \sum_{\alpha \in \mathbb{N}^n} f[\alpha]\, t_{\sigma(1)}^{\alpha_1} \ldots t_{\sigma(n)}^{\alpha_n} \;\in\; R[t_1, \ldots, t_n]$$

Now a polynomial $f \in R[t_1,\dots,t_n]$ is said to be **symmetric** iff it is invariant under any permutation. That is iff for any $\sigma \in S$ we see $\sigma f = f$. We denote the set of all symmetric polynomials by

$$R[t_1,\dots,t_n]_{\text{sym}} \;:=\; \{\, f \in R[t_1,\dots,t_n] \mid \forall\, \sigma \in S_n \,:\, \sigma f = f \,\}$$

And a polynomial $f \in R[t_1,\dots,t_n]$ is said to be **anti-symmetric** iff its sign changes under permutation. That is iff for any $\sigma \in S$ we see $\sigma f = \operatorname{sgn}(\sigma) f$. We denote the set of all anti-symmetric polynomials by

$$R[t_1,\dots,t_n]_{\text{asym}} \;:=\; \{\, f \in R[t_1,\dots,t_n] \mid \forall\, \sigma \in S_n \,:\, \sigma f = \operatorname{sgn}(\sigma) f \,\}$$

Recall that for $k \in 1\dots n$ we defined $\operatorname{Asc}(k,n) = \{\, \alpha : 1\dots r \to 1\dots n \mid \alpha(1) < \alpha(2) < \cdots < \alpha(k) \,\}$ the set of k ascending indices in $1\dots n$. We use this to introduce the k-th **elementary symmetric** polynomial in n variables to be the following polynomial of $R[t_1,\dots,t_n]$:

$$s_k^{(n)}(t_1,\dots,t_n) \;:=\; \sum_{\alpha \in \operatorname{Asc}(k,n)} t_{\alpha(1)} \dots t_{\alpha(k)}$$

Nota for ease of notation it is sometimes beneficial to also take $s_0^{(n)}(t_1,\dots,t_n) := 1$. And by definition it is clear, that $s_1^{(n)}(t_1,\dots,t_n) = t_1 + t_2 + \cdots + t_n$ up to $s_n^{(n)}(t_1,\dots,t_n) = t_1 t_2 \dots t_n$. For ease of understanding let us also write out $s_2^{(n)}(t_1,\dots,t_n)$ in more informal terms

$$s_2^{(n)}(t_1,\dots,t_n) \;=\; t_1t_2 + t_1t_3 + \cdots + t_1t_n + t_2t_3 + t_2t_4 + \cdots + t_{n-1}t_n$$

(7.65) Remark:
Clearly $S_n \times R[t_1,\dots,t_n] \to R[t_1,\dots,t_n] : (\sigma, f) \mapsto \sigma f$ is a group action. That is for any polynomial $f \in R[t_1,\dots,t_n]$ and any permutations $\varrho, \sigma \in S_n$ we have the properties

$$\mathbb{1}_n f \;=\; f \quad \text{and} \quad \sigma\big(\varrho f\big) \;=\; \big(\sigma\varrho\big) f$$

And thereby for a fixed permutation $\sigma \in S_n$ the map $T_\sigma(f) := \sigma f$ is an R-algebra automorphism of $R[t_1,\dots,t_n]$, with inverse $(T_\sigma)^{-1} = T_{\sigma^{-1}}$. That is we have $\sigma\mathbf{0} = \mathbf{0}$, $\sigma\mathbf{1} = \mathbf{1}$ and for any scalar $a \in R$ and polynomials $f, g \in R[t_1,\dots,t_n]$ also

$$\begin{aligned} \sigma(af) &= a\,(\sigma f) \\ \sigma(f+g) &= (\sigma f) + (\sigma g) \\ \sigma(f\cdot g) &= (\sigma f)\cdot(\sigma g) \end{aligned}$$

Prob the properties of a group action are immediately clear from the definition and $(T_\sigma)^{-1} = T_{\sigma^{-1}}$ is consequential. The properties of an R-algebra homomorphism are covered by (7.14), as σf has been defined by the evaluation $f(t_{\sigma(1)},\dots,t_{\sigma(n)})$.

(7.66) Theorem: (viz. 804)
Let $(R,+,\cdot)$ be a commutative ring and fix some $1 \leq n \in \mathbb{N}$. First of all recall the usual degree $\deg(f)$ and weight $\mathrm{wgt}(f)$ of a polynomial $f \in R[t_1,\ldots,t_n]$ in n variables

$$\begin{aligned}\deg(f) &:= \max\{\,\alpha_1+\cdots+\alpha_n \mid \alpha \in \mathbb{N} \text{ and } f[\alpha] \neq 0\,\}\\ \mathrm{wgt}(f) &:= \max\{\,1\cdot\alpha_1+\cdots+n\cdot\alpha_n \mid \alpha \in \mathbb{N} \text{ and } f[\alpha] \neq 0\,\}\end{aligned}$$

(i) For any $k \in 1\ldots n$ the k-th elementary symmetric polynomial $s_k^{(n)}$ in n variables is of degree k. And for any polynomial $f \in R[t_1,\ldots,t_n]$ we find the following identity

$$\begin{aligned}\deg\big(s_k^{(n)}\big) &= k\\ \deg\big(f(s_1^{(n)},\ldots,s_n^{(n)})\big) &= \mathrm{wgt}(f)\end{aligned}$$

(ii) For $k=0$ we have $s_0^{(n)}=1$ and for $n \geq 2$ and $k \geq 1$ the elementary symmetric polynomials in n variables can be generated by recursion on elementary symmetric polynomials in $n-1$ variables:

$$s_k^{(n-1)} + s_{k-1}^{(n-1)}\, t_n = s_k^{(n)}$$

(iii) *Theorem of Vieta*: For any n-tuple $a=(a_1,\ldots,a_n) \in R^n$ of scalars, the product $(t-a_1)\ldots(t-a_n)$ is a polynomial of degree n over R, whose coefficients are the elementary symmetric polynomials evaluated in a, formally we find

$$\prod_{k=1}^{n}(t-a_k) = t^n + \sum_{k=0}^{n-1}(-1)^{n-k}\, s_{n-k}^{(n)}(a)\, t^k$$

In other words: If $f \in R[t]$ splits over R, then we can express its coefficients in terms of the elementary symmetric polynomials in its roots: That is if $f(t)=b(t-a_1)\ldots(t-a_n)$ then for any $k \in 0\ldots n$ the k-th coefficient of f is given to be

$$f[k] = (-1)^{n-k}\, b\, s_{n-k}^{(n)}(a_1,\ldots,a_n)$$

(7.67) Proposition: (viz. 805)
Let $(R,+,\cdot)$ be a commutative ring and regard the polynomial ring $R[t_1,\ldots,t_n]$ in $1 \leq n \in \mathbb{N}$ variables over R. We abbreviate the elementary symmetric polynomials by $s_k := s_k^{(n)} \in R[t_1,\ldots,t_n]$. Then the following statements are true

(i) The symmetric polynomials form an R-subalgebra of $R[t_1,\ldots,t_n]$ and this subalgebra is generated by the elementary symmetric polynomials, formally that is

$$R[t_1,\ldots,t_n]_{\mathrm{sym}} = R[s_1,\ldots,s_n] = \{\, f(s_1,\ldots,s_n) \mid f \in R[t_1,\ldots,t_n]\,\}$$

(ii) Let $f \in R[t_1,\ldots,t_n]$ be any polynomial and regard f in the isomorphic copy $R[t_1,\ldots,t_{n-1}][t_n]$ of $R[t_1,\ldots,t_n]$. That is we write f in the form

$$f = f[0] + f[1]\, t_n + \cdots + f[d]\, t_n^d \quad \text{where} \quad f[k] \in R[t_1,\ldots,t_{n-1}]$$

Now, if f is symmetric, then for any $k \in \mathbb{N}$ the coefficient polynomial $f[k]$ of f is a symmetric polynomial in $R[t_1, \ldots, t_{n-1}]$, as well. That is we get the implication

$$f \text{ is symmetric} \quad \Longrightarrow \quad \forall\, k \in \mathbb{N} \;:\; f[k] \text{ is symmetric}$$

(iii) The evaluation of a polynomial in the elementary symmetric polynomials is injective. That is: For any two polynomials $f, g \in R[t_1, \ldots, t_n]$ we obtain the equivalence

$$f(s_1, \ldots, s_n) \;=\; g(s_1, \ldots, s_n) \quad \Longleftrightarrow \quad f \;=\; g$$

In particular any symmetric polynomial $s \in R[t_1, \ldots, t_n]$ can be expressed uniquely in terms of the elementary symmetric polynomials. And this polynomial g generating s satisfies $\mathrm{wgt}(g) \leq \deg(s)$.

$$\exists!\, g \in R[t_1, \ldots, t_n] \quad \text{such that} \quad s \;=\; g(s_1, \ldots, s_n)$$

(iv) $(\diamondsuit)$ Let $S : R$ be a ring extension and $f \in R[t]$ be a monic polynomial of degree d. Further assume that f splits over S, i.e. there are $x_1, \ldots, x_d \in S$ such that f takes the form

$$(t - x_1) \ldots (t - x_d) \;=\; f(t) \;=:\; t^d + a_1 t^{d-1} + \cdots + a_d$$

If now $s \in R[t_1, \ldots, t_d]$ is a symmetric polynomial, then there is a polynomial $h \in R[t_1, \ldots, t_d]$ such that s evaluated on the roots $x_1, \ldots, x_d$ is the same as h evaluated on the coefficients $a_1, \ldots, a_d$

$$s(x_1, \ldots, x_d) \;=\; h(a_1, \ldots, a_d) \;\in\; R$$

(7.68) Proposition: (viz. 808)
Consider a $(R, +, \cdot)$ commutative ring, that contains the rationals $\mathbb{Q} \subseteq R$ [in other words the integers of R are invertible: $\zeta : \mathbb{Z} \hookrightarrow R^*$]. If now $f \in R[t_1, \ldots, t_n]$ is a polnomial over R, where $1 \leq n \in \mathbb{N}$, then we define its **symmetrization** reps. its **anti-symmetrization** to be the following polynomial again

$$\begin{aligned} f_{\mathrm{sym}} \;&:=\; \frac{1}{n!} \sum_{\sigma \in S_n} \sigma f \\ f_{\mathrm{asym}} \;&:=\; \frac{1}{n!} \sum_{\sigma \in S_n} \mathrm{sgn}(\sigma)\, \sigma f \end{aligned}$$

Thereby $f_{\mathrm{sym}} \in R[t_1, \ldots, t_n]_{\mathrm{sym}}$ and $f_{\mathrm{asym}} \in R[t_1, \ldots, t_n]_{\mathrm{asym}}$ truly are symmetric resp. anti-symmetric polynomials and the symmetrization of f equals f if and only if f was symmetric beforehand (likewise for anti-symmetric polynomials)

$$\begin{aligned} f \;=\; f_{\mathrm{sym}} \quad &\Longleftrightarrow \quad f \;\in\; R[t_1, \ldots, t_n]_{\mathrm{sym}} \\ f \;=\; f_{\mathrm{asym}} \quad &\Longleftrightarrow \quad f \;\in\; R[t_1, \ldots, t_n]_{\mathrm{asym}} \end{aligned}$$

Nota as $S : f \mapsto f_{\mathrm{sym}}$ is R-linear we thereby find, that S is a projection $S^2 = S$ on the R-module $R[t_1, \ldots, t_n]$ with image $R[t_1, \ldots, t_n]_{\mathrm{sym}}$. Likewise the same is true for $A : f \mapsto f_{\mathrm{asym}}$.

7.6 Derivations

(7.69) Definition:
Let $(R,+,\cdot)$ be a commutative ring and A be an R-algebra, then a map d of the form $d : A \to A$ is said to be a **derivation** on A, iff it satisfies the following two properties

(1) d is R-linear

(2) For any $f, g \in A$ we get $d(f \cdot g) = d(f) \cdot g + f \cdot d(g)$

Property (2) is called the *product rule* of a derivation. The set of all derivations on A (which is a sub-module of $\mathrm{end}(A)$ the R-module endomorphisms of A) is denoted, by

$$\mathrm{der}(A) \;:=\; \{\, d : A \to A \mid (1) \text{ and } (2) \,\}$$

Nota however $\mathrm{der}(A)$ is *not* a sub-algebra of $\mathrm{end}(A)$, as the composition $d_2 d_1$ does not satisfy the product rule any more, but we rather get

$$(d_2 d_1)(f \cdot g) \;=\; d_2\big(d_1(f \cdot g)\big) \;=\; d_2 d_1 f \cdot g + d_1 f \cdot d_2 g + d_2 f \cdot d_1 g + f \cdot d_2 d_1 g$$

(7.70) Proposition: (viz. 826)
Let R be a commutative ring and A be an R-algebra. Denote the neutral elements of addition and multiplication on A be 0_A and 1_A respectively. If now $d \in \mathrm{der}(A)$ is any derivation on A, then we get the following properties

(i) For any $a \in R$ we have $d(a1_A) = 0_A$

(ii) *General product rule*: For any $f_1, \ldots, f_n \in A$ we have

$$d\big(f_1 \cdot \ldots \cdot f_n\big) \;=\; \sum_{i=1}^{n} f_1 \cdot \ldots \cdot f_{i-1} \cdot d(f_i) \cdot f_{i+1} \cdot \ldots \cdot f_n$$

(iii) If A is a commutative R-algebra containing $f, g \in A$ and $m, n \in \mathbb{N}$ are numbers, such that $n \geq 1$, then any derivation $d \in \mathrm{der}(A)$ satisfies the following two identities

$$\begin{aligned} d\big(f^n\big) &= n d(f) \cdot f^{n-1} \\ d^m\big(f \cdot g\big) &= \sum_{k=0}^{m} \binom{m}{k} d^k(f) \cdot d^{m-k}(g) \end{aligned}$$

(iv) *Quotient rule:* If A is a commutative R-algebra and $U \subseteq A$ is a multiplicatively closed set, that does not contain any zero-divisors $U \cap \mathrm{zd}(A) = \emptyset$, then any derivation $d \in \mathrm{der}(A)$ can be extended to a derivation $U^{-1}d \in \mathrm{der}(U^{-1}A)$ by letting

$$U^{-1}d\left(\frac{f}{u}\right) \;:=\; \frac{d(f) \cdot u - f \cdot d(u)}{u^2}$$

And thereby we get $(U^{-1}d)(f/1) = d(f)/1$ for any $f \in A$. That is we can reconstruct d from $U^{-1}d$ and therefore - by abuse of notation - it is customary to denote $U^{-1}d$ by d again.

(v) If A is a commutative R-algebra and $U \subseteq A$ is a multiplicatively closed set, that does not contain any zero-divisors $U \cap \mathrm{zd}(A) = \emptyset$, then this extension is injective R-module homomorphism from the derivations of A into the derivations of $U^{-1}A$

$$\mathrm{der}(A) \hookrightarrow \mathrm{der}(U^{-1}A) \; : \; d \mapsto U^{-1}d$$

And thereby the image of this monomorphism is given to be the set of all derivations D of $U^{-1}A$, such that for any $f \in A$ there is some $f' \in A$ such that $D(f/1) = f'/1$, formally

$$\Big\{ U^{-1}d \mid d \in \mathrm{der}(A) \Big\} \;\; = \;\; \Big\{ D \in \mathrm{der}(U^{-1}A) \mid \forall\, f \in A \; \exists\, f' \in A \; : \; D(f/1) = f'/1 \Big\}$$

(7.71) Example: (viz. 829)
The classical example is the following: Let $(R, +, \cdot)$ be a commutative ring and regard $A := R[t]$ the polynomial ring over R. Then we obtain a derivation d on A by defining $d(f) := f'$, where

$$f' \;\; := \;\; \sum_{k=1}^{\infty} k f[k]\, t^{k-1} \;\; \in \;\; R[t]$$

(7.72) Definition:
Let $(R, +, \cdot)$ be a commutative ring, fix $1 \leq n \in \mathbb{N}$ and $i \in 1 \ldots n$ and regard the polynomial ring $R[t_1, \ldots, t_n]$. Then we define a derivation ∂_i called the **formal derivative** with respect to the variable t_i in the following way: For any polynomial $f \in R[t_1, \ldots, t_n]$ write f as a polynomial in t_i over a polynomial ring in $n-1$ variables, that is $f \in R[t_1, \ldots, t_{i-1}, t_{i+1}, \ldots, t_n][t_i]$, then we define $\partial_i f := f'$, that is

$$\partial_i f \;\; = \;\; \sum_{k=1}^{\infty} \left(\sum_{\alpha_i = k} f[\alpha] \prod_{j \neq i} t_j^{\alpha_j} \right) k\, t_i^{k-1}$$

where the sum runs over all $\alpha = (\alpha_1, \ldots, \alpha_n) \in \mathbb{N}^n$ with $\alpha_i = k$ and the product runs over the finite set $j \in \{ 1, \ldots, n \} \setminus \{ i \}$. In other words, we define ∂_i by linear expansion of the following assignment of the basis $\{ t^\alpha \mid \alpha \in \mathbb{N}^n \}$ of monomials of $R[t_1, \ldots, t_n]$: Abbreviate $\delta_i = (\delta_{i,j}) \in \mathbb{N}^n$ then $\partial_i t^\alpha$ is

$$\partial_i t^\alpha \;\; := \;\; \begin{cases} 0 \text{ if } \alpha_i = 0 \\ \alpha_i\, t^{\alpha - \delta_i} \text{ if } \alpha_i \geq 1 \end{cases}$$

By (7.73.(i)) all the formal derivatives ∂_i and ∂_j are mutually commutative and hence it makes sense to define their products ∂^α for any multi-index $\alpha = (\alpha_1, \ldots, \alpha_n) \in \mathbb{N}^n$ by

$$\partial^\alpha \;\; := \;\; \prod_{i=1}^{n} \partial_i^{\alpha_i} \;\; \in \;\; \mathrm{end}(R[t_1, \ldots, t_n])$$

Nota if we need to emphasize the variable t_i the formal derivative ∂_i acts on, we sometimes use the following, more elaborate, notation for the formal derivative instead

$$\frac{\partial f}{\partial t_i} \;\; = \;\; \frac{\partial}{\partial t_i} f \;\; := \;\; \partial_i f$$

(7.73) Proposition: (viz. 830)
Let $(R,+,\cdot)$ be a commutative ring and $1 \leq n \in \mathbb{N}$. Recall that for $\alpha = (\alpha_1,\ldots,\alpha_n) \in \mathbb{N}$ we defined $\alpha! = \prod_i \alpha_i!$. Then the partial derivatives ∂_i for $i \in 1\ldots n$ satisfy all of the following properties

(i) For any $i, j \in 1\ldots n$ the partial derivatives ∂_i and ∂_j commute, that is for all $f \in R[t_1,\ldots,t_n]$ we have the identity $\partial_i(\partial_j(f)) = \partial_j(\partial_i(f))$.

(ii) Consider any two multi-indices $\alpha = (\alpha_1,\ldots,\alpha_n)$ and $\beta = (\beta_1,\ldots,\beta_n) \in \mathbb{N}^n$. If there is some $i \in 1\ldots n$ such that $\alpha_i > \beta_i$ then we get $\partial^\alpha t^\beta = 0$. And if $\alpha_i \leq \beta_i$ for any $i \in 1\ldots n$ then we obtain the following identity

$$\partial^\alpha t^\beta \;=\; \frac{\beta!}{(\beta-\alpha)!}\, t^{\beta-\alpha}$$

(iii) If R is an integral domain then $\{\,\partial_1,\ldots,\partial_n\,\}$ is algebraically independent, that is we find an isomorphism of the commutative algebra $R[\partial_1,\ldots,\partial_n] \subseteq \mathrm{end}(R[t_1,\ldots,t_n])$ to a polynomial ring in n variables of the following form

$$R[d_1,\ldots,d_n] \;\xrightarrow{\sim}\; R[\partial_1,\ldots,\partial_n] \;:\; f \mapsto f(\partial_1,\ldots,\partial_n)$$

(iv) *Chain rule of differentiation:* Consider any $1 \leq m, n \in \mathbb{N}$ and polynomials $g \in R[t_1,\ldots,t_m]$ and (for any $j \in 1\ldots n$) $f_j \in R[s_1,\ldots,s_m]$. Then we get the identity

$$\frac{\partial}{\partial s_i} g(f_1,\ldots,f_n) \;=\; \sum_{j=1}^{n} \frac{\partial f_j}{\partial s_i} \cdot \frac{\partial g}{\partial t_j}(f_1,\ldots,f_n)$$

(v) *Taylor expansion theorem:* If R contains $\mathbb{Q}$ as a sub-ring [that is $\{\,k1_R \mid 1 \leq k \in \mathbb{N}\,\} \subseteq R^*$] and we fix any point $x = (x_1,\ldots,x_n) \in R^n$ then any polynomial $f \in R[t_1,\ldots,t_n]$ can be written in the following form

$$f \;=\; \sum_{\alpha\in\mathbb{N}^n} \frac{1}{\alpha!}\big(\partial^\alpha f\big)(x) \cdot (t-x)^\alpha$$

(7.74) Proposition: (viz. 554)
Let $(R,+,\cdot)$ be a commutative ring and $1 \leq n \in \mathbb{N}$. Then the derivations on the polynomial ring $R[t_1,\ldots,t_n]$ satisfy the following properties

(i) If d_1 and $d_2 \in \mathrm{der}(R[t_1,\ldots,t_n])$ are any derivations on the polynomial ring then (a) $d_1 = d_2$ and (b) for all $i \in 1\ldots n$ we have $d_1(t_i) = d_2(t_i)$ are equivalent.

Proof of (7.74):

(i) The direction (a) $\implies$ (b) is trivial and for (b) $\implies$ (a) it suffices to check $d_1(t^\alpha) = d_2(t^\alpha)$ for any $\alpha \in \mathbb{N}$, due to the R-linearity of both d_1 and d_2. Let us first prove $d_1(t_i^k) = d_2(t_i^k)$ for any $i \in 1\ldots n$ and $k \in \mathbb{N}$, by induction on k:

For $k = 0$ we have $t_i^k = \mathbf{1}$ and thereby by (7.70.(i)) $d_1(\mathbf{1}) = 0 = d_2(\mathbf{1})$. For $k = 1$ the identity $d_1(t_i^k) = d_2(t_i^k)$ is precisely the content of (b). Thus we perform the induction step $k \mapsto k+1$: By the product rule we have

$$d_1\big(t_i^{k+1}\big) \;=\; d_1\big(t_i^k \cdot t_i\big) \;=\; d_1\big(t_i^k\big)\cdot t_i + t_i^k \cdot d_1\big(t_i\big)$$

By the induction hypothesis we have $d_1(t_i^k) = d_2(t_i^k)$ and $d_1(t_i) = d_2(t_i)$ is granted by (b). So if we apply the product rule to d_2 we end up with the same term, as we can replace d_2 by d_1 on the right-hand side and hence the induction is complete.

In particular we have proved the claim in case $n = 1$. For higher n we use induction on n again: Suppose we already have $d_1(t^\alpha) = d_2(t^\alpha)$ for any $\alpha \in \mathbb{N}^{n-1}$, then we continue

$$\begin{aligned} d_1\big(t^\alpha t_n^{\alpha_n}\big) &= d_1\big(t^\alpha\big) \cdot t_n^{\alpha_n} + t^\alpha \cdot d_1\big(t_n^{\alpha_n}\big) \\ &= d_2\big(t^\alpha\big) \cdot t_n^{\alpha_n} + t^\alpha \cdot d_2\big(t_n^{\alpha_n}\big) \;=\; d_2\big(t^\alpha t_n^{\alpha_n}\big) \end{aligned}$$

7.8 Solution Formulae

Linear algebra set out to provide a theory of solving systems of linear equations, which we finished in section 4.3 to satisfaction. The gaussian algorithm is an efficient way of finding the set of solutions. Alas, this is the one and only situation that allows a definitive answer. Another classical question are polynomial equations in one variable. We will see that even in this case there will not be an ultimate answer, only special cases. So a general theory of solving systems of polynomial equations in several variables is utopic.

The following problem is ancient: Given a positive (real) number $r > 0$, how do you find a root of r, that is a number x such that $x^2 = r$. The following iterative method is described by Heron in the first century AB, already: Interpret r as the area of a rectangle. The length of the sides shall be a and b, that is $ab = r$. What we need is a square of the same area, if x is the side length of the square, we have $x^2 = r$. As one side of the rectangle exceeds x and one falls short it makes sense to take one side as the average $a' = (a+b)/2$. In order to keep the area fixed at r the other side then becomes $b' := r/a'$. The following illustration depicts the situation where $a = 4$ and $b = 2$, that is $r = 8$.

In the next step we get $a' = 3$ and $b' = 8/3$. It can already be seen that the new rectangle is closer to a square, than the one before. So we can iterate and have reason to assume, that we come ever closer to a square. That is by iterating the rectangle over and over we can approximate $x = \sqrt{r}$. So let us take an algebraic look and compute the new value of a' in general

$$a' \;=\; \frac{a+b}{2} \;=\; \frac{a+r/a}{2} \;=\; \frac{a^2+r}{2a}$$

So in modern terms we have found a recursion formula that should converge to $\sqrt{r}$. This might not be wholly satisfactory, but as a and b will stay rational and $\sqrt{r}$ is irrational, this is actually the best, we can hope for. The following proposition tells us, that this method truly yields a way of approximating $x = \sqrt{8}$ to arbitrary precision, as the recursion converges:

(7.75) Proposition: (viz. 836)

(i) Consider any real number $r \in \mathbb{R}$ with $r > 0$. Then there is another, uniquely determined real number $x \in \mathbb{R}$ with $x > 0$ such that $x^2 = r$. And we find a sequence $(a_n) \subseteq \mathbb{Q}$ of rational numbers that converges to $(a_n) \to x$ in the following way: Start with $a_0 := 1$ and use the recursion formula

$$a_{n+1} \;:=\; \frac{a_n^2 + r}{2a_n}$$

(ii) Consider any complex number $z \in \mathbb{C}$ with $z \neq 0$. Then there are exactly 2 complex numbers w_1, $w_2 \in \mathbb{C}$ such that $w_1^2 = z = w_2^2$: Write z in polar coordinates, that is $z = r(\cos(\alpha) + i\sin(\alpha))$, for some $r > 0$ and $\alpha \in \mathbb{R}$. By (i) there is some $x > 0$ with $x^2 = r$, let us denote it by $\sqrt{r} := x$. Then the roots of z are given to be

$$w_{1/2} \;=\; \pm\sqrt{r}\left(\cos\left(\frac{\alpha}{2}\right) + i\sin\left(\frac{\alpha}{2}\right)\right)$$

So in the complex numbers $\mathbb{C}$ the equation $w^2 = z$ always has a (for $z \neq 0$ even 2) solution. In general we cannot expect the equation $x^2 = a$ to have a solution. Even for the reals $\mathbb{R}$, we do not get solutions for $a < 0$. And for the rational numbers $\mathbb{Q}$ even $x^2 = 2$ does not have a solution. But we encountered this before: The equation $2x = 3$ does not have a solution in the integers $\mathbb{Z}$. Our solution was to enhance the integers by fractions, which led to the rationals $\mathbb{Q}$. More generally we introduced the quotient field of an integral domain and even studied localisations. There's nothing wrong with doing this again: The following construction enhances the base ring by picking up a square root ω of an arbitrary element s:

(7.76) Example: (viz. 837)
Let $(R, +, \cdot)$ be a commutative ring and fix any $s \in R$. The following construction yields a ring, called $R[\sqrt{s}]$, such that R can be regarded as a subring of $R[\sqrt{s}]$ and that contains an element $\omega \in R[\sqrt{s}]$ such that $\omega^2 = s$. The construction is simple: We take $R[\sqrt{s}] := R^2$ as an R-module and only need to define the multiplication on $R[\sqrt{s}]$

$$\begin{pmatrix} a \\ b \end{pmatrix}\begin{pmatrix} c \\ d \end{pmatrix} \;:=\; \begin{pmatrix} ac + bds \\ ad + bc \end{pmatrix}$$

Under these operations $R[\sqrt{s}]$ turns into a commutative R-algebra with unit element $1 = (1,0)$. If we take $\omega := (0,1)$, then it is clear, that $\omega^2 = (s,0)$ which we will interpret as s. Note that 1 and ω are the euclidean base elements of R^2 and therefore any element of $R[\sqrt{s}]$ can be written in the form $(a,b) = a + b\omega$ uniquely. In this form the multiplication of $R[\sqrt{s}]$ reads as

$$\big(a + b\omega\big)\big(c + d\omega\big) \;=\; \big(ac + bds\big) + \big(ad + bc\big)\omega$$

Also note that we obtain a monomorphism of rings $R \hookrightarrow R[\sqrt{s}] : a \mapsto (a,0)$ and we use this monomorphism to interpret R as the subring $\{\,(a,0) \mid a \in R\,\}$ of $R[\sqrt{s}]$. In other words $R[\sqrt{s}] : R$ is a ring extension. For $s = -1$ this is precisely the construction used for the complex numbers $\mathbb{C} = \mathbb{R}[\sqrt{-1}]$. We will present two equivalent constructions of the ring $R[\sqrt{s}]$ below. But first for any $a + b\omega \in R[\sqrt{s}]$ let us define $\nu(a + b\omega) := a^2 - sb^2 \in R$. Then the units of $R[\sqrt{s}]$ are given to be those $a + b\omega$ for which $\nu(a + b\omega)$ is a unit in R. And we can use this to compute the inverse of $a + b\omega$, as well: $(a + b\omega)^{-1} = (a^2 - sb^2)^{-1}(a - b\omega)$

$$R[\sqrt{s}]^* \;=\; \{\, a + b\omega \mid a^2 - sb^2 \in R^* \,\}$$

(i) In a first construction we find an isomorphic version of this ring: Start with $R[t]$ the polynomial ring in one variable and take the ideal $\mathfrak{w} := (t^2 - s)R[t]$ in this ring. Then we obtain an isomorphism of R-algebras that maps $1 = (1,0) \mapsto 1 + \mathfrak{w} = 1$ and $\omega = (0,1) \mapsto t + \mathfrak{w}$, given by

$$R[\sqrt{s}] \xrightarrow{\sim} R[t] \Big/ (t^2 - s)R[t] \; : \; a + b\omega \mapsto a + bt + \mathfrak{w}$$

(ii) Another way to look at $R[\sqrt{s}]$ is the following monomorphism of R-algebras, that allows us to interpret $R[\sqrt{s}]$ as a sub-algebra of the matrix ring $\mathrm{mat}_2(R)$

$$R[\sqrt{s}] \hookrightarrow \mathrm{mat}_2(R) \; : \; a + b\omega \mapsto \begin{pmatrix} a & b \\ sb & a \end{pmatrix}$$

(7.77) Proposition: (viz. 839)
Let $(R, +, \cdot)$ be a commutative ring, for any $b \in R$ and $a \in R^*$ let us abbreviate $b/a := ba^{-1} = a^{-1}b$. Also let $R^\square := \{ r^2 \mid r \in R \}$. Now assume that a and $2 := 1 + 1 \in R^*$ are invertible and b, $c \in R$ are arbitrary. Then we regard the following polynomial of degree 2

$$f(t) \;\; := \;\; at^2 + bt + c$$

Let us abbreviate $\Delta := b^2 - 4ac$, then we can rewrite f in its so-called *vertex form*, which is given to be

$$f(t) \;\; = \;\; a\left(t + \frac{b}{2a}\right)^2 - \frac{\Delta}{4a}$$

And thereby we get the following statements: (i) f has no roots in R, if and only if $\Delta \notin R^\square$. (ii) If $\Delta = \omega^2$ for some $\omega \in R$, then f splits over R, as it can be written in the following form

$$f(t) \;\; = \;\; a\left(t + \frac{b+\omega}{2a}\right)\left(t + \frac{b-\omega}{2a}\right)$$

In particular if R is an integral domain and $\omega^2 = \Delta$ again, then the roots of f are uniquely determined:

$$\mathbb{V}(f) \;\; = \;\; \left\{ \frac{-b-\omega}{2a}, \frac{-b+\omega}{2a} \right\}$$

(7.78) Remark:

(i) The above proposition (7.77) provides the theory of solving polynomial equations in one variable of degree 2. For example take the complex numbers $\mathbb{C}$ as the base ring and regard the equation

$$az^2 + bz + c \;\; = \;\; 0$$

where a, b and $c \in \mathbb{C}$ and $a \neq 0$. We want to find the solutions $z \in \mathbb{C}$ of this equation. To do this compute $\Delta := b^2 - 4ac$. If $\Delta = 0$, then clearly $\omega := 0$ satisfies $\omega^2 = \Delta$. And if $\Delta \neq 0$ then write Δ in polar coordinates $\Delta = r(\cos(\alpha) + i\sin(\alpha))$, where $r > 0$ and $\alpha \in \mathbb{R}$. Then by (7.75.(ii)) admits

a root $\omega = \sqrt{\Delta}$, that is we get $\omega^2 = \Delta$ by taking

$$\omega \;:=\; \sqrt{r}\left(\cos\left(\frac{\alpha}{2}\right) + i\sin\left(\frac{\alpha}{2}\right)\right)$$

Now that we have the square root ω of the determinant Δ we know by (7.77) again, that the solution(s) z of the above quadratic equation are given to be

$$z_{1/2} \;=\; \frac{-b \pm \omega}{2a}$$

(ii) In case of the real numbers $\mathbb{R}$ things are a little more restrained: Again let a, b and $c \in \mathbb{R}$ with $a \neq 0$. As above in (i) we look for solutions $x \in \mathbb{R}$ of the equation

$$ax^2 + bx + c \;=\; 0$$

Again let $\Delta := b^2 - 4ac$. If $\Delta = 0$ then take $\omega := 0$ again. And if $\Delta > 0$, then (7.75.(i)) tells us that Δ has a uniquely determined square root $\omega := \sqrt{\Delta} > 0$. That is to say $\omega^2 = \Delta$. And thereby we find the solution(s) of the above quadratic equation to be literally the same

$$x_{1/2} \;=\; \frac{-b \pm \omega}{2a}$$

However, in case $\Delta < 0$, there is no $\omega \in \mathbb{R}$ with $\omega^2 = \Delta$ and thereby this equation does not have any solutions in $\mathbb{R}$. What we can do, is take to $\Delta \in \mathbb{C}$: Here Δ has a root, namely $\omega := i\sqrt{-\Delta}$. And with this ω is stow, the formula for $x_{1/2}$ yields the solutions of the quadratic equation in $\mathbb{C}$.

Chapter 8

Ring Extensions

8.1 Basic Notions

The most famous ring extension is $\mathbb{C}$ over $\mathbb{R}$ and this already gets the idea across: There is some base ring $R = \mathbb{R}$ and a larger ring $S = \mathbb{C}$, that contains R. In this case we write $S : R$ spoken S *over* R. Another popular example is the polynomial ring $R[t]$ over some commutative ring R. But let us take a closer look: What does it mean, that R is *contained* in S? Clearly $R \subseteq S$ could be a subset, but this need not be the case. With $R[t] : R$ for example there only is an embedding

$$R \hookrightarrow R[t] \;:\; a \mapsto a\,t^0$$

Another important example is a localization $U^{-1}R : R$ of some commutative ring R. In this case we have a canonical homomorphism again

$$\kappa \;:\; R \to U^{-1}R \;:\; a \mapsto \frac{a}{1}$$

but κ only is injective iff $U \subseteq \text{NZD}(R)$. So in general we may not even expect an embedding of the sub-ring. This is the reason why we give a very general definition of a ring extension $S : R$, even though we usually think of a sub-ring $R \subseteq S$. This will be a fixed homomorphism $\alpha : R \to S$ of rings, but the next lemma tells us this is just the same as an R-algebra S. However you will see, that the intuition of a sub-ring $R \subseteq S$ will work just fine.

(8.1) Lemma: (viz. 1213)

(i) If $(R, +, \cdot)$ is a commutative ring and A a commutative R-algebra, then we obtain the so-called **structural homomorphism** $\alpha : R \to A$ by defining $\alpha(a)$ to be the scalar-multiplication of $a \in R$ and $1_A \in A$ in A. And thereby this α is a homomorphism of ring

$$\alpha \;:\; R \to A \;:\; a \mapsto a\,1_A$$

(ii) If $(R, +, \cdot)$ and $(S, +, \cdot)$ are commutative rings and $\alpha : R \to S$ is a homomorphism of rings, then S can be turned into an R-algebra using the multiplication of $\alpha(a)$ and s in S as scalar multiplication

$$R \times S \to S \;:\; (a, s) \mapsto \alpha(a) \cdot s$$

Nota as $\alpha(a) \in S$ satisfies $\alpha(a) = \alpha(a) \cdot 1_S = a\,1_S$ it is clear, that this α thereby becomes the *structural homomorphism* of S under this scalar multiplication induced by α.

(iii) Let $(R, +, \cdot)$ be a commutative ring and $S \neq 0$ be a non-zero commutative R-algebra. If S is torsion free, as an R-module (that is for any $a \in R$ and any $s \in S$ we have $as = 0$ implies $a = 0$ or $s = 0$) then the structural homomorphism $\alpha : R \to S : a \mapsto a\,1_S$ is injective. If S is an integral domain the converse implication is true, as well.

$$S \text{ is } R\text{-torsion free} \quad \Longrightarrow \quad \alpha \text{ is injective}$$

Nota if we take $R := \mathbb{Z}[r]$ and $S := \mathbb{Z}[r,s]/rs\mathbb{Z}[r,s]$ as an R-algebra induced - in the sense of (ii) - by $\alpha : a(r) \mapsto a(r) + rs\mathbb{Z}[r,s]$, then S is not torsion-free, as $r(s + rs\mathbb{Z}[r,s]) = 0 + rs\mathbb{Z}[r,s]$ by construction, but α is injective, still, as $s \mid rs \mid a(r)$ would imply $s \mid a(r)$, which cannot be.

(8.2) Definition: (viz. 1213)
We call the ordered pair (R, T) a **ring extension** - written, as $T : R$ - iff $(R, +, \cdot)$ is a commutative ring and T is a commutative, unital R-algebra. In this case we interpret R as a sub-ring of T, that is by abuse of notation we sometimes denote the following R-subalgebra of T by R again:

$$R\,1_T \;:=\; \{\, a\,1_T \mid a \in R \,\} \quad \leq_{\mathsf{a}} \quad T$$

The **rank** of $T : R$ is defined to be the rank of T as an R-module and will be denoted by $[T : R]$. The extension $T : R$ is said to be **finite** iff $[T : R] < \infty$, that is iff T is finitely generated, as an R-module.

$$[T : R] \;:=\; \mathrm{rank}_R(T)$$

And finally S is said to be an **intermediate ring** of $T : R$ - written, as $T : S : R$, iff $S \leq_{\mathsf{r}} T$ is a sub-ring of T that also satisfies one of the following three equivalent properties

(a) $\{\, a1_T \mid a \in R \,\} \subseteq S$

(b) for any $a \in R$ and $s \in S$ we get $as \in S$

(c) $S \leq_{\mathsf{a}} T$ is an R-sub-algebra

(8.3) Example:

(i) If $(T, +, \cdot)$ is a commutative ring and $R \leq_{\mathsf{r}} T$ is a sub-ring, then $T : R$ clearly is a ring extension. The scalar multiplication ax where $a \in R$ and $x \in T$ is just the usual multiplication $\cdot$ of T. And an intermediate ring S is just another sub-ring $S \leq_{\mathsf{r}} T$ such that $R \subseteq S$.

(ii) Clearly $\mathbb{C} : \mathbb{R}$ and $\mathbb{R} : \mathbb{Q}$ are ring extensions of fields - these are called *field extensions*. Thereby $\mathbb{R}$ is an intermediate ring of $\mathbb{C} : \mathbb{Q}$. Also $\mathbb{Q} : \mathbb{Z}$ is a ring extension, but not a field extension.

(iii) If $(R,+,\cdot)$ is a commutative ring and $R[t]$ the polynomial ring over R, then we already mentioned, that $R[t] : R$ is a ring extension. This is generally true for any commutative monoid A, which gives rise to the ring extension $R[t \mid A] : R$. Recall that the scalar multiplication is point-wise, that is

$$a \sum_{\alpha \in A} f[\alpha]\, t^{\alpha} \;=\; \sum_{\alpha \in A} a f[\alpha]\, t^{\alpha}$$

(iv) If $(R,+,\cdot)$ is a commutative ring and $U \subseteq R$ is a multiplicatively closed subset, then $U^{-1}R$ is an R-algebra [and thereby a ring extension $U^{-1}R : R$] under the scalar multiplication

$$a\frac{b}{u} \;=\; \frac{ab}{u}$$

Nota that is $U^{-1}R : R$ is induced, by $\kappa : R \mapsto U^{-1}R : a \mapsto a/1 = a1_{U^{-1}R}$. Recall that by (2.116) κ is injective, if and only if $U \subseteq \text{NZD}(R)$ - that is if for any $u \in U$ and any $a \in R$ we get $au = 0 \implies a = 0$. This situation will be generalized in the next example:

(v) The most general and most important example is (8.1.(ii)): If $(R,+,\cdot)$ and $(S,+,\cdot)$ are commutative rings and $\alpha : R \to S$ is a fixed homomorphism of rings, then $S : R$ is a ring-extension taking the multiplication of $\alpha(a)$ and s in S as scalar multiplication

$$as \;:=\; \alpha(a) \cdot s$$

(vi) If $S : R$ is a ring extension and $\alpha : R \to S : a \mapsto a\,1_S$ its structural homomorphism, then this induces another R-algebra homomorphism $\overline{\alpha} : R[t] \to S[t]$ by virtue of (7.12.(iv)).

$$\overline{\alpha}\left(\sum_{k=0}^{\infty} f[k]\, t^k\right) \;:=\; \sum_{k=0}^{\infty} \alpha(f[k])\, t^k$$

By abuse of notation we will denote the $\overline{\alpha}$ by α again and in this sense any ring extension $S : R$ already is accompanied by this ring extension $S[t] : R[t]$. It is clear that this example extends to arbitrary polynomial rings $S[t \mid A] : R[t \mid A]$ over a commutative monoid $(A,+)$, if we take to

$$\overline{\alpha}\left(\sum_{\gamma \in A} f[\gamma]\, t^{\gamma}\right) \;:=\; \sum_{\gamma \in A} \alpha(f[\gamma])\, t^{\gamma}$$

(vii) If R is a commutative ring, M any R-module and $\varphi \in \text{end}(M)$ an R-module endomorphism of M. Then we studied $f(\varphi)$, where $f \in R[t]$ is a polynomial, in (5.40). Thereby

$$S \;:=\; R[\varphi] \;=\; \{\, f(\varphi) \mid f \in R[t] \,\} \;\leq_{\text{r}}\; \text{end}(M)$$

is a commutative ring, as any $f(\varphi)$ commutes with any other $g(\varphi)$, where $f, g \in R[t]$. And $R[\varphi]$ clearly is an R-algebra under the scalar multiplication $a\,f(\varphi) = (af)(\varphi)$ such that we have another ring extension $R[\varphi] : R$.

(viii) If $(S,+,\cdot)$ is a commutative ring and $\mathfrak{u}$, $\mathfrak{v} \trianglelefteq_{\mathsf{i}} S$ are ideals of S such that $\mathfrak{u} \subseteq \mathfrak{v}$, then we obtain another ring-extension of the quotient rings of S

$$S\big/_{\mathfrak{v}} : S\big/_{\mathfrak{u}}$$

under the scalar multiplication $(a+\mathfrak{u})(x+\mathfrak{v}) := ax+\mathfrak{v}$. This is well defined, as $a+\mathfrak{u} = b+\mathfrak{u}$ implies $u := b-a \in \mathfrak{u} \subseteq \mathfrak{v}$ such that $ux \in \mathfrak{v}$ and therefore $bx+\mathfrak{v} = (a+u)x+\mathfrak{v} = ax+ux+\mathfrak{v} = ax+\mathfrak{v}$.

(ix) A special case of (vii) is $\mathfrak{u} = 0$, hereby we have $S/\mathfrak{u} = S$ canonically such that for any ideal $\mathfrak{v} \trianglelefteq_{\mathsf{i}} S$ we have the ring extension (under the scalar multiplication $a(x+\mathfrak{v}) = ax+\mathfrak{v}$)

$$S\big/_{\mathfrak{v}} : S$$

(8.4) Definition: (viz. 1214)
Let $S : R$ be any ring extension and $U \subseteq S$ be an arbitrary subset of S. Then we denote the R-sub-algebra of A *generated* by U by the following symbol

$$R[U] \;:=\; \langle U\rangle_{\mathsf{a}} \;=\; \bigcap \{\, Q \leq_{\mathsf{a}} S \mid U \subseteq Q \,\}$$

Let us give a more explicit construction of the intermediate ring $R[U]$: If $u \in S$ is any element of S then we write $R[u]$ instead of $R[\{\, u \,\}]$ and this is just the image of the evaluation homomorphism by u, that is

$$R[u] \;:=\; \{\, f(u) \mid f \in R[t] \,\} \;=\; \left\{ \sum_{k=0}^{n} a_k u^k \;\middle|\; n \in \mathbb{N},\, a_k \in R \right\}$$

Likewise if $u_1, u_2, \ldots, u_n \in S$ are finitely many elements of S, then we write $R[u_1,\ldots,u_n]$ instead of $R[\{\, u_1,\ldots,u_n \,\}]$ and again this is the image of the evaluation homomorphism in the u_k

$$\begin{aligned} R[u_1,\ldots,u_n] &= \{\, f(u_1,\ldots,u_n) \mid f \in R[t_1,\ldots,t_n] \,\} \\ &= \left\{ \sum_{\alpha\in\mathbb{N}^n} a_\alpha u^\alpha \;\middle|\; n \in \mathbb{N},\, a_\alpha \in R \right\} \end{aligned}$$

also confer to example (7.21) for more comments on this. Clearly this is an intermediate ring of $S : R$, as it is the image of a homomorphism of R-algebras. Finally, for a general subset $U \subseteq S$ we find the intermediate ring of $S : R$ generated by U to be the following: If $U = \emptyset$ then $R[U] = R$ and if $U \neq \emptyset$ is non-empty, $R[U]$ is the union of all finitely generated sub-rings $R[u_1,\ldots,u_n]$ where $u_k \in U$, formally

$$R[U] \;=\; \left\{ f(u_1,\ldots,u_n) \;\middle|\; \begin{array}{l} 1 \leq n \in \mathbb{N}, \\ f \in R[t_1,\ldots,t_n], \\ u_1,\ldots,u_n \in U \end{array} \right\} \;=\; \bigcup \left\{ R[u_1,\ldots,u_n] \;\middle|\; \begin{array}{l} 1 \leq n \in \mathbb{N}, \\ u_1,\ldots,u_n \in U \end{array} \right\}$$

(8.5) Proposition: (viz. 1214)
If $S : R$ is a ring-extension, $u_1, u_2, \ldots, u_n \in S$ are (not necessarily distinct) elements of S and $k \in 1 \ldots n$ then we have the following identity of intermediate rings of $S : R$

$$R[u_1, \ldots, u_k][u_{k+1}, \ldots, u_n] \;=\; R[u_1, \ldots, u_n]$$

Note that the case $k = 0$ is trivial, as we have $R[\emptyset] = R$ as mentioned in the definition above. A little more general: If $U, V \subseteq S$ are subsets of S, then $R[U][V]$ is an intermediate ring of $S : R[U]$ and hence of $S : R$, as well. And for these we have the following identity of sets

$$R[U][V] \;=\; R[U \cup V]$$

(8.6) Lemma: (viz. 1215)
Let $T : R$ be any ring-extension and $S \subseteq T$ be any subset. Then we find that the following three statements are equivalent

(a) $T : S : R$ is an intermediate ring

(b) for any subset $U \subseteq S$ we get $R[U] \subseteq S$

(c) for any $u, v \in S$ we get $R[u, v] \subseteq S$

(8.7) Proposition: (viz. 1216)
Let S be an intermediate ring of the ring extension $T : R$. Also consider some non-empty subsets $X \subseteq S$ and $Y \subseteq T$ of S and T respectively. Then we denote the set $XY := \{\, xy \mid x \in X, y \in Y \,\} \subseteq T$ of point-wise products and thereby obtain the following statements:

(i) If X generates S as an R-module $S = \mathrm{Lh}_R(X)$ and Y generated T as an S-module $T = \mathrm{Lh}_S(Y)$ then XY generates T as an R-module, that is

$$T \;=\; \mathrm{Lh}_R(XY)$$

(ii) If X is R-linearly independent and Y is S-linearly independent, then the set XY of point-wise products is R-linearly independent, as well.

(iii) In particular: If X is an R-basis of S and Y is an S-basis of T, then XY is an R-basis of T.

(iv) Hence in any ring extension $T : R$ with an intermediate ring S the degree of $T : R$ cannot exceed the product of the degrees of $T : S$ and $S : R$. Formally we have the inequality

$$[T : R] \;\leq\; [T : S] \cdot [S : R]$$

And if R and S are fields, then the degree of $T : R$ even equals the product of $T : S$ and $S : R$. That is - if R and S are fields - we have the equality

$$[T : R] \;=\; [T : S] \cdot [S : R]$$

(8.8) Remark:
Consider any ring extension $S : R$ and denote its structural homomorphism by $\alpha : R \to S$. That is we think of R as the sub-ring $\alpha(R) = \{\, a\,1_S \mid a \in R \,\}$ of S. Then by (8.3.(vi)) this gives rise to another ring extension $S[t] : R[t]$. In this sense: If $g_1, \ldots, g_r \in S[t]$ are polynomials, then $g_1 \cdot \ldots \cdot g_r \in R[t]$ means

$$\forall\, k \in \mathbb{N} \;\; : \;\; \big(g_1 \cdot \ldots \cdot g_r\big)[k] \;\in\; \alpha(R)$$

And likewise, if $f \in R[t]$ then in $g_1 \cdot \ldots \cdot g_r = f$ the left-hand side polynomial lies in $S[t]$ and the right-hand side polynomial lies in $R[t]$. To say that they are equal means

$$\forall\, k \in \mathbb{N} \;\; : \;\; \big(g_1 \cdot \ldots \cdot g_r\big)[k] \;=\; \alpha(f[k])$$

(8.9) Proposition: (viz. 1225)
If $S : R$ is ring extensions under its structural homomorphisms $\alpha : R \to S$ and $f \in R[t]$ is a polynomial over R, then we say that f **splits** over S, iff there are elements $s_1, \ldots, s_n \in S$ such that f can be written as a product of the linear factors $t - s_k$, formally that is

$$f(t) \;\;=\;\; \mathrm{lc}(f) \prod_{k=1}^{n} \big(t - s_k\big)$$

And if $T : S$ is another ring extensions under the structural homomorphism $\beta : S \to T$, then we regard $T : S$ as a ring extension under $\beta\alpha : R \to T$. Thereby, if $f \in R[t]$ splits over S (as above), then it also splits over T, as we get

$$f(t) \;\;=\;\; \mathrm{lc}(f) \prod_{k=1}^{n} \big(t - \beta(s_k)\big)$$

(8.10) Lemma: (viz. 1217)

(i) *Lemma of Kronecker*: If $(R, +, \cdot)$ is any commutative ring and $f \in R[t]$ is a monic polynomial of degree $n := \deg(f) \geq 1$. Then we take a look at the R-algebra

$$S \;\;:=\;\; R[t] \,\Big/\, fR[t]$$

Thereby $S : R$ is a ring-extension, in which we can consider R as a sub-ring under the monomorphism $\alpha : R \hookrightarrow S : a \mapsto at^0 + fR[t]$ of rings. Also S is a free, finitely generated R-module of dimension $[S : R] = n$. An R-basis of S is given by the following set

$$\Big\{\, t^k + fR[t] \mid 0 \leq k < n \,\Big\}$$

(ii) If $(R, +, \cdot)$ is any commutative ring and $f \in R[t]$ is a monic polynomial of degree $n = \deg(f) \geq 1$ again, then there is another commutative ring $(S, +, \cdot)$ satisfying the following three properties:

(1) $S : R$ can be turned into a ring extension under an injective homomorphism $\alpha : R \hookrightarrow S$

(2) S is finitely generated, as an R-module, its rank being bound by $[S : R] \leq n!$

(3) The polynomial f *splits* over S, that is: There are elements $s_1, \ldots, s_n \in S$ such that f can be written as a product of linear factors of the form $t - s_k$ over S, formally

$$f(t) \;=\; \prod_{k=1}^{n} (t - s_k)$$

(iii) If $(R, +, \cdot)$ is any commutative ring and $f_1, \ldots, f_r \in R[t]$ are monic polynomials of the degrees $n(i) = \deg(f_i) \geq 1$ again, then there is another commutative ring $(S, +, \cdot)$ satisfying

(1) $S : R$ can be turned into a ring extension under an injective homomorphism $\alpha : R \hookrightarrow S$

(2) S is finitely generated, as an R-module, in other words $[S : R] < \infty$

(3) All the polynomials f_1 to f_r *split* over S simultaneously, that is: For any $i \in 1 \ldots r$ there are elements $s_{i,j} \in S$ (where $j \in 1 \ldots n(i)$) such that f_i can be written as a product of linear factors of the form $t - s_{i,j}$ over S, formally again

$$f_i(t) \;=\; \prod_{j=1}^{n(i)} (t - s_{i,j})$$

(iv) If $(E, +, \cdot)$ is a field and $f \in E[t]$ is any polynomial of $n := \deg(f) \geq 1$, then there even is another field $(F, +, \cdot)$ satisfying the following three properties:

(1) $F : E$ can be turned into a ring extension under an injective homomorphism $\alpha : E \hookrightarrow F$

(2) F is finitely generated, as an E-vector-space, its dimension being bound by $[F : E] \leq n!$

(3) The polynomial f *splits* over F, that is: There are elements $a \in E^*$ and $x_1, \ldots, x_n \in F$ such that f can be written as a product of linear factors of the form $t - x_k$ over F, formally

$$f(t) \;=\; a \prod_{k=1}^{n} (t - x_k)$$

(8.11) Remark:

(i) The property that $f \in R[t]$ is a *monic* polynomial is absolutely crucial for this result. If we start with $2t - 1 \in \mathbb{Z}[t]$, then $\mathbb{Z}[t] \twoheadrightarrow \mathbb{Z}[1/2] : g \mapsto g(1/2)$ has the kernel $f\mathbb{Z}[t]$, such that $\mathbb{Z}[t]/f\mathbb{Z}[t]$ and $\mathbb{Z}[1/2]$ are isomorphic. Yet $\mathbb{Z}[1/2]$ is not finitely generated over $\mathbb{Z}$. Also refer to (8.27) for this.

(ii) The benefit of this construction is the following: Let R be any commutative ring and $f \in R[t]$ be a monic polynomial over R. It may happen that f does not have any root in R, such as $f(t) = t^2 + 1 \in \mathbb{R}[t]$. We now extend R to S, thereby R is embedded into S by virtue of

$$R \hookrightarrow S \;:\; a \mapsto at^0 + fR[t]$$

But if we take $x := t + fR[t]$, then $x \in S$ and x is a root of f, as now $f(x) = f(t + fR[t]) = f(t) + fR[t] = 0 + fR[t]$. That is we have found a larger ring S, that contains R, in which f has a root. Starting with $R = \mathbb{R}$ and $f(t) = t^2 + 1 \in \mathbb{R}[t]$ this is the construction that yielded $S = \mathbb{C}$.

(iii) Iterating (i) is precisely the method we used to find the splitting ring S of f in (ii), by inductively building up S, adding one root s_1 at a time and proceeding with the rest f without $(t - s_1)$. This result has a sister-theorem in the case of fields, where $f \in E[t]$ splits in a field extension $F : E$.

(iv) Consider the R-module endomorphism $\varphi : S \to S : s \mapsto xs$ where $x = t + fR[t]$ again. Then the R-basis $\{ 1, x, \ldots, x^{n-1} \}$ of S in (i) is just the cyclic basis $\{ \varphi^k(x) \mid 0 \leq k < n \}$ of x under φ. In this light (i) here and (5.57.(iii)) are much the same result, in different settings.

8.2 Transfer of Ideals

(8.12) Definition:
Let $(R,+,\cdot)$ and $(S,+,\cdot)$ be commutative rings and $\alpha : R \to S$ be a fixed homomorphism of rings, between these. If now $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is an ideal of R and $\mathfrak{u} \trianglelefteq_{\mathrm{i}} S$ is an ideal of S. Then we define the **pull-back** $\mathfrak{u} \cap R$ of $\mathfrak{u}$ and the **push-forward** $\mathfrak{a}S$ of $\mathfrak{a}$ to be the following ideals of R and S respectively:

$$\mathfrak{u} \cap R \;:=\; \alpha^{-1}(\mathfrak{u}) \;=\; \{\, a \in R \mid \alpha(a) \in \mathfrak{u} \,\}$$

$$\mathfrak{a}S \;:=\; \langle \alpha(\mathfrak{a}) \rangle_{\mathrm{i}} \;=\; \langle \alpha(a) \mid a \in \mathfrak{a} \rangle_{\mathrm{i}}$$

Nota thereby $\mathfrak{u} \cap R \trianglelefteq_{\mathrm{i}} R$ is an ideal, according to proposition (1.76.(vii)) and $\mathfrak{a}S \trianglelefteq_{\mathrm{i}} S$ is an ideal, as it has been defined as the ideal generated by the subset $\alpha(\mathfrak{a}) \subseteq S$. This means that any element $f \in \mathfrak{a}S$ is of the following form for some $s_1,\ldots,s_n \in S$ and $a_1,\ldots,a_n \in \mathfrak{a}$:

$$f \;=\; \alpha(a_1)\cdot s_1 + \cdots + \alpha(a_n)\cdot s_n$$

(8.13) Remark:
If $(S,+,\cdot)$ is any ring and $R \leq_{\mathrm{r}} S$ is a subring, then of course $R \subseteq S$ is a subset. The inclusion map of sets $\iota : R \to S : a \mapsto a$ is a homomorphism of rings, that turns $S : R$ into a ring extension (well, this means S should be commutative). For this structural homomorphism we get $\iota^{-1}(\mathfrak{u}) = \{\, a \in R \mid a \in \mathfrak{u} \,\} = \mathfrak{u} \cap R$ are identical *as sets*, for any subset $\mathfrak{u} \subseteq S$. This is where the notation of the pull-back comes from: In case of ambiguity the pull-back and intersection yield precisely the same ideal.

Likewise if the structural homomorphism $\alpha : R \hookrightarrow S$ is injective, then we get an isomorphic copy $\iota(R) \subseteq S$ of R inside S. Then for any ideal $\mathfrak{u} \trianglelefteq_{\mathrm{i}} S$ we can look at the intersection $\mathfrak{u} \cap \iota(R) \trianglelefteq_{\mathrm{i}} \iota(R)$ of sets. Then $\iota(\iota^{-1}(\mathfrak{u})) = \mathfrak{u} \cap \iota(R)$, that is the pull-back $\iota^{-1}(\mathfrak{u})$ is just the preimage of $\mathfrak{u} \cap \iota(R)$ inside R. Thus the pull-back $\mathfrak{u} \cap R$ is an isomorphic copy of an intersection $\mathfrak{u} \cap \iota(R)$ of sets, inside R. The only real difference occurs, whenever α is *not* injective.

(8.14) Proposition: (viz. 1220)
Consider the commutative rings $(R,+,\cdot)$ and $(S,+,\cdot)$, an arbitrary subset $A \subseteq R$ and a homomorphism $\alpha : R \to S$ of rings. Let $\mathfrak{a} := \langle A \rangle_{\mathrm{i}} \trianglelefteq_{\mathrm{i}} R$ be the ideal generated by A, then the push-forward of $\mathfrak{a}$ is just the ideal of S generated by $\alpha(A)$:

$$\mathfrak{a}S \;=\; \langle \alpha(A) \rangle_{\mathrm{i}} \;\trianglelefteq_{\mathrm{i}}\; S$$

(8.15) Proposition: (viz. 1220)
Let $(R,+,\cdot)$ and $(S,+,\cdot)$ be commutative rings and $\alpha : R \to S$ be a fixed homomorphism of rings, between these. Then the transfer of ideals forms a covariant Galois connection

$$\begin{array}{rcl} \mathrm{Ideal}(R) & \to & \mathrm{Ideal}(S) \\ \mathfrak{a} & \mapsto & \mathfrak{a}S \\ \mathfrak{u} \cap R & \hookleftarrow & \mathfrak{u} \end{array}$$

That is for any ideals $\mathfrak{a}$, $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ we find that $\mathfrak{a} \subseteq \mathfrak{b}$ implies $\mathfrak{a}S \subseteq \mathfrak{b}S$. Likewise for any ideals $\mathfrak{u}$, $\mathfrak{v} \trianglelefteq_{\mathrm{i}} S$ we find that $\mathfrak{u} \subseteq \mathfrak{v}$ implies $\mathfrak{u} \cap R \subseteq \mathfrak{v} \cap R$. And finally we have the inclusions

$$\begin{aligned} \mathfrak{a} &\subseteq (\mathfrak{a}S) \cap R \\ (\mathfrak{u} \cap R)\, S &\subseteq \mathfrak{u} \end{aligned}$$

As always in a Galois connection: If $\mathfrak{a} = \mathfrak{u} \cap R$ is the pull-back of some ideal $\mathfrak{u} \trianglelefteq_{\mathrm{i}} S$ then we get $(\mathfrak{a}S) \cap R = \mathfrak{a}$. Likewise if $\mathfrak{u} = \mathfrak{a}S$ is the push-out of some ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$, then we get $(\mathfrak{u} \cap R)S = \mathfrak{u}$. And thereby we obtain a 1-to-1 correspondence, of the form

$$\begin{array}{rcl} \{\, \mathfrak{u} \cap R \mid \mathfrak{u} \trianglelefteq_{\mathrm{i}} S \,\} & \longleftrightarrow & \{\, \mathfrak{a}S \mid \mathfrak{a} \trianglelefteq_{\mathrm{i}} R \,\} \\ \mathfrak{a} & \mapsto & \mathfrak{a}S \\ \mathfrak{u} \cap R & \hookleftarrow & \mathfrak{u} \end{array}$$

For prime ideals this correspondence has even weaker requirements. To be precise, for any prime ideal $\mathfrak{p} \in \operatorname{Spec}(R)$ we find that the above equation holds true if and only if $\mathfrak{p}$ is the pull-back of some prime ideal $\mathfrak{q} \in \operatorname{Spec}(S)$. That is the following two statements are equivalent:

(a) $\mathfrak{p} = (\mathfrak{p}S) \cap R$

(b) $\exists\, \mathfrak{q} \in \operatorname{Spec}(S) \;:\; \mathfrak{p} = \mathfrak{q} \cap R$

(8.16) Remark:

(i) Both of the above inclusions in (8.15) need not be equalities: As a counter-example for the first lets us consider $S := \mathbb{Q}$, $R := \mathbb{Z}$ and $\mathfrak{a} := 2\mathbb{Z}$. Then $1 \in \mathfrak{a}S$ and hence $\mathfrak{a}S = \mathbb{Q}$ such that $\mathfrak{a}S \cap R = \mathbb{Z}$ exceeds $\mathfrak{a}$. As a counter-example for the second let us take to $S := \mathbb{Q}[t]$, $R := \mathbb{Q}$ and $\mathfrak{u} := tS$. Then clearly $\mathfrak{u} \cap R = \{0\}$ such that $(\mathfrak{u} \cap R)S = \{0\}$ is smaller than $\mathfrak{u}$.

(ii) If $S : R$ is any ring extension, then the pull-back $\mathfrak{q} \cap R$ of a prime ideal $\mathfrak{q} \trianglelefteq_{\mathrm{i}} S$ is a prime ideal again, due to (2.17). However the push-out $\mathfrak{p}S$ of a prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ need *not* be prime again. As a counter-example, take a look at $\mathbb{Z}[\sqrt{2}] : \mathbb{Z}$ and the prime ideal $2\mathbb{Z} \trianglelefteq_{\mathrm{i}} \mathbb{Z}$. Then the push-out of $2\mathbb{Z}$ is $2\mathbb{Z}[\sqrt{2}]$, but $2 = \sqrt{2} \cdot \sqrt{2}$ no longer is prime.

(8.17) Remark: (viz. 1221)
Let us take a look at a slightly more general situation: Consider homomorphisms of rings, of the form $\iota : R \to S$ and $\pi : S \to R$, such that $\pi\iota = \mathbb{1}_R$. We consider $S : R$ as a ring-extension, induced by ι. If now $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ and $\mathfrak{u} \trianglelefteq_{\mathrm{i}} S$ are ideals, then we obtain the following statements:

(i) π is a homomorphism of R-algebras

(ii) $\mathfrak{a}S \subseteq \pi^{-1}(\mathfrak{a})$

(iii) $\mathfrak{u} \cap R \subseteq \pi(\mathfrak{u})$

However the converse inclusions need not be true: For a counter-example let $R := \mathbb{Q}[x]$ and $S := \mathbb{Q}[x,y]$. Here $\iota : R \to S$ is the canonical inclusion $\iota(f)[\alpha,\beta] = f[\alpha]$ for $\beta = 0$ and $= 0$ for $\beta \neq 0$. And $\pi : S \to R$ is the evaluation homomorphism $\pi(g) = g(x,0)$. Then clearly $\pi\iota(f) = f$.

Now take $\mathfrak{a} := xR$, then $\mathfrak{a}S = xS$ and hence $y \notin \mathfrak{a}S$. However $\pi(y) = 0 \in \mathfrak{a}$ and hence $y \in \pi^{-1}(\mathfrak{a})$. Likewise let $\mathfrak{u} := (y+1)S$, then $\mathfrak{u} \cap R = 0$, as the only $f \in R$ such that $\iota(f)$ is divisible by $y+1$ is $f = 0$. Yet $\pi(y+1) = 1$ and hence $1 \in \pi(\mathfrak{u})$.

(8.18) Proposition: (viz. 1222)
Let $(R,+,\cdot)$, $(S,+,\cdot)$ and $(T,+,\cdot)$ be commutative rings and $\alpha : R \to S$ and $\beta : S \to T$ be homomorphisms of rings. Then we regard $S : R$ and $T : S$ as ring extensions. Likewise $T : R$ is a ring extension induced by $\beta\alpha : R \to T$. If now $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R$ and $\mathfrak{c} \trianglelefteq_{\mathfrak{i}} T$ are ideals, then we obtain the following identities concerning the transferred ideals:

$$\begin{aligned} (\mathfrak{a}S)T &= \mathfrak{a}T \\ (\mathfrak{c} \cap S) \cap R &= \mathfrak{c} \cap R \end{aligned}$$

(8.19) Proposition: (viz. 1222)
Consider a homomorphism $\alpha : R \to S$ between the commutative rings R and S. Thus $S : R$ is a ring extension under α and any ideal induces another ring extension on the quotient rings, according to:

(i) If $\mathfrak{u} \trianglelefteq_{\mathfrak{i}} S$ is an ideal and $\mathfrak{a} := \mathfrak{u} \cap R$ is the pull-back of $\mathfrak{u}$, then we obtain a well-defined, injective homomorphism of rings, by virtue of

$$R\big/_{\mathfrak{a}} \hookrightarrow S\big/_{\mathfrak{u}} : a + \mathfrak{a} \mapsto \alpha(a) + \mathfrak{u}$$

(ii) If $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} S$ is an ideal and $\mathfrak{u} := \mathfrak{a}S$ is the push-forward of $\mathfrak{a}$, then we obtain a well-defined, homomorphism of rings and in case $\mathfrak{a} = (\mathfrak{a}S) \cap R$ this homomorphism even is injective

$$R\big/_{\mathfrak{a}} \hookrightarrow S\big/_{\mathfrak{u}} : a + \mathfrak{a} \mapsto \alpha(a) + \mathfrak{u}$$

(8.20) Remark:
If $\alpha : R \twoheadrightarrow S$ is surjective, then clearly the homomorphisms in (i) and (ii) in the proposition above, are surjective, as well - and hence isomorphisms. It may also happen, that they are surjective, even if α is not, e.g. in the case $R = \mathbb{Z}$, $\mathfrak{a} = 2\mathbb{Z}$ and $S = \mathbb{Q}$ we have $\mathfrak{a}\mathbb{Q} = \mathbb{Q}$. But generally this is not the case: Consider any ring A, even the algebraically closed field $A = \mathbb{C}$ and let $R := A[s]$, $\mathfrak{a} := sA[s]$ and $S = A[s,t]$. Then $\mathfrak{a}S = sS$ and thereby we get

$$\begin{array}{ccccc} A & \xrightarrow{\sim} & A[s]\big/_{sA[s]} & \hookrightarrow & A[s,t]\big/_{sA[s,t]} \\ a & \mapsto & a + sA[s] & \mapsto & a + sA[s,t] \end{array}$$

Yet the latter ring is isomorphic, to $A[t] \xrightarrow{\sim} A[s,t]/sA[s,t]$ under $f(t) \mapsto f(t) + sA[s,t]$ and hence the monomorphism is not surjective, it cannot reach any element of the form $tg(s,t) + sA[s,t]$.

(8.21) Proposition: (viz. 1222)
Consider any ring extension $S : R$ and a non-empty index set $\Lambda \neq \emptyset$. For any $\lambda \in \Lambda$ let $\mathfrak{a}_\lambda \trianglelefteq_{\mathrm{i}} R$ be an ideal of R, respectively $\mathfrak{u}_\lambda \trianglelefteq_{\mathrm{i}} S$ be an ideal of S. For ease of notation, also let $\mathfrak{a}$, $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ and $\mathfrak{u}$, $\mathfrak{v} \trianglelefteq_{\mathrm{i}} S$ be ideals. Then we find the following statements

(i) The pull-back of ideals is compatible with intersections of ideals. For the sum (of any) and product (of finitely many) ideals, the pull-back still satisfy a one-sided inclusion:

$$\begin{aligned}\left(\bigcap_{\lambda\in\Lambda} \mathfrak{u}_\lambda\right) \cap R &= \bigcap_{\lambda\in\Lambda} (\mathfrak{u}_\lambda \cap R)\\ \left(\sum_{\lambda\in\Lambda} \mathfrak{u}_\lambda\right) \cap R &\supseteq \sum_{\lambda\in\Lambda} (\mathfrak{u}_\lambda \cap R)\\ (\mathfrak{u} \cap R) \cdot (\mathfrak{v} \cap R) &\subseteq (\mathfrak{u} \cdot \mathfrak{v}) \cap R\end{aligned}$$

(ii) The push-out of ideals is compatible with taking sums (of any) and (of finitely many) products of ideals. For the intersection ideals, the push-out still satisfies a one-sided inclusion:

$$\begin{aligned}\left(\bigcap_{\lambda\in\Lambda} \mathfrak{a}_\lambda\right) S &\subseteq \bigcap_{\lambda\in\Lambda} (\mathfrak{a}_\lambda S)\\ \left(\sum_{\lambda\in\Lambda} \mathfrak{a}_\lambda\right) S &= \sum_{\lambda\in\Lambda} (\mathfrak{a}_\lambda S)\\ (\mathfrak{a} S) \cdot (\mathfrak{b} S) &= (\mathfrak{a} \cdot \mathfrak{b}) S\end{aligned}$$

Nota in fact we will prove that the sum of the ideals $\mathfrak{a}_\lambda S$ equals the following set: Let $A \subseteq R$ be the union of the ideals $A := \bigcup_\lambda \mathfrak{a}_\lambda$, then the sum of the ideals contains finite sums of elements of the form $s_i\, \alpha(a_i)$ where $s_i \in S$ and $a_i \in A$. Formally, that is

$$\left(\sum_{\lambda\in\Lambda} \mathfrak{a}_\lambda\right) S = \left\{ \sum_{i=1}^{n} s_i\, \alpha(a_i) \;\middle|\; n \in \mathbb{N},\, s_i \in S,\, a_i \in A \right\}$$

(8.22) Example:
The inclusions in the above proposition may be strict: E.g. consider the ring extension $\mathbb{Z}[t] : \mathbb{Z}$ and regard the ideals $\mathfrak{u}_1 = (t+1)S$ and $\mathfrak{u}_2 = (t-1)S$, where $S = \mathbb{Z}[t]$ of course. Then it is clear, that

$$2 = (t+1) - (t-1) \in (\mathfrak{u}_1 + \mathfrak{u}_2) \cap \mathbb{Z}$$

Yet $\mathfrak{u}_1 \cap \mathbb{Z} = 0$: Suppose there was some $f \in \mathbb{Z}[t]$ such that $g := (t+1)f \in \mathbb{Z}$, then we find $g[0] = f[0]$ and for any $k \geq 1$ also $0 = g[k] = f[k] + f[k-1]$. Thus if $f[0] \neq 0$ is non-zero, then f would not be a polynomial, but a formal power series, as for any $k \geq 1$ we had $f[k] = -f[k-1]$. Likewise $\mathfrak{u}_2 \cap \mathbb{Z} = 0$, as in this case $f[k] = f[k-1]$ for any $k \geq 1$, such that

$$2 \notin 0 = (\mathfrak{u}_1 \cap \mathbb{Z}) + (\mathfrak{u}_2 \cap \mathbb{Z})$$

The counter-example for the intersection is a little more intricate: For the base ring take $R = \mathbb{Z}[t_1, t_2]$ and the ideals $\mathfrak{a}_1 = t_1 R$ and $\mathfrak{a}_2 = t_2 R$. As R is an UFD we have $\mathfrak{a}_1 \cap \mathfrak{a}_2 = t_1 t_2 R$. The extension ring is

$$S \;:=\; R[u] \Big/ (t_1 u - t_2 u) R[u] \;=\; \mathbb{Z}[t_1, t_2, u] \Big/ (t_1 u - t_2 u)\mathbb{Z}[t_1, t_2, u]$$

Let us abbreviate $\mathfrak{v} := (t_1 u - t_2 u)\mathbb{Z}[t_1, t_2, u]$ Then $R \hookrightarrow S$ under $f(t_1, t_2) \mapsto f(t_1, t_2, 0) + \mathfrak{v}$ such that we can even regard R as a subset of S. Let us also abbreviate $s := u + \mathfrak{v} \in S$. Then by (8.14) the ideals $\mathfrak{a}_i S = t_i S$ and $(\mathfrak{a}_1 \cap \mathfrak{a}_2)S = t_1 t_2 S$ are principal again and thereby $t_i s \in \mathfrak{a}_i S$. But by construction we have $t_1 s = t_2 s$ such that we thereby get

$$t_1 s \;\in\; \mathfrak{a}_1 S \cap \mathfrak{a}_2 S$$

However $t_1 s \notin (\mathfrak{a}_1 \cap \mathfrak{a}_2)S = t_1 t_2 S$ - suppose there was some $f \in \mathbb{Z}[t_1, t_2, u]$ such that $t_1 s = t_1 t_2 f + \mathfrak{v} \in S$, then $t_1(t_2 f - u) \in \mathfrak{v}$, but $t_2 f$ can't get rid of the t_2. Hence we have found an element

$$t_1 s \;\notin\; (\mathfrak{a}_1 \cap \mathfrak{a}_2)S$$

Shifting Ideals in Polynomial Rings

We conclude this section by presenting a situation in which the transfer of ideals is particularly well behaved: Ideals in polynomial rings over the same base ring, with differently many variables. Though it is not needed for the rest of this text, this is the algebraic counterpart of regarding an algebraic set in ambient spaces of different dimension.

(8.23) Definition:

If $I \neq \emptyset$ is a non-epmty index set and $(R, +, \cdot)$ is a commutative ring, then we have introduced the polynomial ring $R[t_i \mid i \in I] = R[t \mid \mathbb{N}^{\oplus I}]$ over the monoid $\mathbb{N}^{\oplus I}$ in (7.10). For the time being let us abbreviate this by $R[I]$. And for systematic reasons we would also like to introduce $R[\emptyset] := R$.

If now I and J are any index sets, such that $I \cap J = \emptyset$ [we will usually take $I \subseteq K$ and $J = K \setminus I$ for some set K] then it is clear, that $\mathbb{N}^{\oplus I} \times \mathbb{N}^{\oplus J} = \mathbb{N}^{\oplus (I \cup J)}$ canonically. And by (7.12.(vi)) this gives rise to an isomorphism of R-algebras

$$\begin{array}{ccc} R[u_k \mid k \in I \cup J] & \xrightarrow{\sim} & R[s_i \mid i \in I][t_j \mid j \in J] \\ \displaystyle\sum_{(\alpha,\beta) \in \mathbb{N}^{\oplus I} \times \mathbb{N}^{\oplus J}} f[\alpha, \beta]\, u^{(\alpha,\beta)} & \mapsto & \displaystyle\sum_{\beta \in \mathbb{N}^{\oplus J}} \left(\sum_{\alpha \in \mathbb{N}^{\oplus I}} f[\alpha, \beta]\, s^\alpha \right) t^\beta \end{array}$$

In particular if $I \subseteq K$ are nested index sets, then we let $J := K \setminus I$ and can thereby regard $R[t_i \mid i \in I]$ as a subset of $R[t_k \mid k \in K] = R[t_i \mid i \in I][t_j \mid j \in J]$. This is due to the fact, that the structural homomorphism of the ring extension is injective

$$\iota_I^K \;:\; R[t_i \mid i \in I] \hookrightarrow R[t_k \mid k \in K] \;:\; f \mapsto f\mathbf{1}$$

The coefficients of $f\mathbf{1}$ are given to be $(f\mathbf{1})[\gamma] = f[\alpha]$ whenever $\gamma = (\alpha, 0) \in \mathbb{N}^{\oplus I} \times \mathbb{N}^{\oplus J}$ and $(f\mathbf{1})[\gamma] = 0$, whenever $\gamma = (\alpha, \beta)$ for some $\beta \neq 0$. In the following we are interested in the properties of the transfer of ideals in ring-extensions of the form $R[t_k \mid k \in K] : R[t_i \mid i \in I]$ where $I \subseteq K$. It will turn out, that in this case the transfer of ideals is far better behaved, than in general ring extensions:

(8.24) Proposition: (viz. 1225)
Let $(R, +, \cdot)$ be a commutative ring and I, J and K be arbitrary index sets, such that $I \subseteq J \subseteq K$. By abuse of notation, let us abbreviate $R[I] := R[t_i \mid i \in I]$, likewise $R[J] := R[t_j \mid j \in J]$ and $R[K] := R[t_k \mid k \in K]$. As above let $\iota_I^J : R[I] \hookrightarrow R[J]$ an $\iota_J^K : R[J] \hookrightarrow R[K]$ be the canonical embeddings. Then we get the following statements:

(i) Regardless of the cardinality of I, the polynomial ring always is a union of a net of finitely generated sub-rings of $R[I]$. Formally this can be put as

$$R[I] \;=\; \bigcup \Big\{ \iota_\Omega^I(R[\Omega]) \;\Big|\; \Omega \subseteq I \text{ finite} \Big\}$$

(ii) The canonical embeddings satisfy $\iota_I^K = \iota_J^K \iota_I^J$ and there are homomorphisms $\pi_I^J : R[J] \twoheadrightarrow R[I]$ of R-algebras, that are uniquely determined by the following mapping property for all $j \in J$

$$\pi_I^J(t_j) \;=\; \begin{cases} t_j \text{ if } j \in I \\ 0 \text{ if } j \in J \setminus I \end{cases}$$

And these homomorphism satisfy the properties (1) π_I^J is surjective, (2) $\pi_I^J \iota_I^J = \mathbb{1}_{R[I]}$ and (3) for any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R[I]$ we get $\pi_I^J(\mathfrak{a}\, R[J]) \subseteq \mathfrak{a}$.

(iii) Consider $f_1, \ldots, f_r \in R[J]$ and $a, a_1, \ldots, a_r \in R[I]$ and let us abbreviate $\widehat{a} := \iota_I^J(a)$ and likewise $\widehat{a}_l := \iota_I^J(a_l) \in R[J]$. If we now have $\widehat{a} = f_1\widehat{a}_1 + \cdots + f_r\widehat{a}_r$ then

$$\exists\, b_1, \ldots, b_r \in R_k \quad \text{such that} \quad a = b_1\, a_1 + \cdots + b_r\, a_r$$

(iv) Expanding an ideal into a larger ring and returning to a smaller ring actually is unaffected by the preceding expansion. Formally, for any ideals $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R[I]$ and $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R[J]$ we get the identities

$$\begin{aligned} \big(\mathfrak{a}\, R[K]\big) \cap R[J] &= \mathfrak{a}\, R[J] \\ \big(\mathfrak{b}\, R[K]\big) \cap R[I] &= \mathfrak{b} \cap R[I] \end{aligned}$$

Nota In the special case $I = J$ we get $(\mathfrak{a}\, R[K]) \cap R[I] = \mathfrak{a}$. That is: If we expand $\mathfrak{a}$ and return, nothing changes. This is far from true for general ring-extensions.

(v) Recall $I \subseteq J$ and let us denote $H := J \setminus I$ and $S := R[I]$. Then we identify $R[J]$ with its isomorphic image $R[J] = R[I][J \setminus I] = S[H]$. If $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R[I]$ is any ideal, then $\mathfrak{a}\, R[J] = \mathfrak{a}[H]$ and we obtain the following isomorphism of R-algebras

$$\mathfrak{a}[H] \;:=\; \Big\{ g \in S[H] \;\Big|\; \forall\, \alpha \in \mathbb{N}^{\oplus H} : g[\alpha] \in \mathfrak{a} \Big\}$$

$$R[J]\,\big/_{\mathfrak{a}\,R[J]} \xrightarrow{\sim} \left(R[I]\,\big/_{\mathfrak{a}}\right)[H] \;:\; g + \mathfrak{a}\,R[J] \mapsto \sum_{\alpha\in\mathbb{N}^{\oplus H}} \big(g[\alpha] + \mathfrak{a}\big)t^{\alpha}$$

Thereby: An ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R[I]$ is prime, if and only if the push-out $\mathfrak{p}\,R[J] \trianglelefteq_{\mathrm{i}} R[J]$ is a prime ideal again. Nota In the special case $I = \emptyset$ we have $S = R$ and $H = J$ and thereby any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ satisfies $\mathfrak{a}\,R[J] = \mathfrak{a}[J] = \big\{\, g \in R[J] \mid \forall\, \alpha \in \mathbb{N}^{\oplus J} : g[\alpha] \in \mathfrak{a} \,\big\}$.

(vi) Let J be some index set and consider a countable, ascending chain of subsets $I_0 \subseteq I_1 \subseteq I_2 \subseteq \ldots$ of indices, that exhaust J. That is J is the union

$$J \;:=\; \bigcup_{n\in\mathbb{N}} I_n$$

Then for an arbitrary ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R[J]$ we find, that $\mathfrak{a}$ is the capstone of the ascending chain of ideals $(\mathfrak{a} \cap R[I_{n-1}])\,R[J] \subseteq (\mathfrak{a} \cap R[I_n])\,R[J]$. This is to say, that

$$\sum_{n=0}^{\infty} \big(\mathfrak{a} \cap R[I_n]\big)\,R[I_\infty] \;=\; \mathfrak{a}$$

8.3 Integral Extensions

The historic origin of the following notions is a classic problem: The *squaring of the circle*: That is we want to find (ideally even to construct) a square, that has the same area, as a given circle. It is well known that the area of a circle of radius r is πr^2 and the area of a square of side length a is a^2. So this amounts to solving the equation

$$a^2 \;=\; \pi r^2$$

to a. The solution is $a = r\sqrt{\pi}$ of course, but this is not so simple, as it may seem to us today: The reals are complete and hence satisfy the supremum property. So $\sqrt{\pi}$ clearly is a *real* number. But classically there only are rational numbers. So the question is: Is $\sqrt{\pi} = a/r$ a *rational* number? In other words still: Does π satisfy a polynomial of the form $t^2 - q \in \mathbb{Q}[t]$ for some $q = a/r \in \mathbb{Q}$?
But maybe this is a little too much to ask for. We could just start with *any* polynomial $f \in \mathbb{Q}[t]$ (apart from $f = 0$ of course) for which $f(\pi) = 0$. So, is there any? It turns out the answer is *no*! For any $f \in \mathbb{Q}[t]$ we have $f(\pi) \neq 0$ unless we started with $f = 0$ in the first place (though the proof of this is far from obvious). This means that π is *not* a combination of algebraic operations (including roots of any power), of rational numbers, whatsoever. In this sense π is outside algebra's reach, if we start from $\mathbb{Q}$. You have to use infinite computations in order to reach it. The following beautiful formula of Leibnitz is an example of this (though its proof is not easy, as well):

$$\frac{\pi}{4} \;=\; 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9} + \cdots \;=\; \sum_{k=0}^{\infty} \frac{(-1)^k}{2k+1}$$

Of course we would have to establish a meaning, what an infinite sum is supposed to be, but we leave this to any basic course on analysis. Mathematicians use to say that π is *transcendent* over $\mathbb{Q}$, which is to say that you cannot reach it by finite means. The complementary notion is: If there is some $f \in \mathbb{Q}[t]$ with $f \neq 0$ such that $f(x) = 0$, then x is said to be *algebraic* or *integral* over $\mathbb{Q}$ (we will soon make a slight distinction between these two notions, but over $\mathbb{Q}$ they coincide). All the rational numbers and any roots thereof are examples of this. But there also are exceptions, like π and e.
The notion of being transcendent resp. integral not only is of interest in number fields, where it is the staging point of quite some theory. But it turns out that the same property has deep geometric interpretations and hence is one of the fundamental concepts of algebraic geometry. But we are getting ahead of ourselves, lets start with the basic definitions:

(8.25) Definition: Intergal Extensions:
Let $S : R$ be a ring extension and consider some element $x \in S$. Then x is said to be **algebraic over** R, iff for any element $x \in S$ there is some non-zero polynomial $f \in R[t]$ such that x is a root of this polynomial; formally

$$\exists\; f \in R[t] \;\;:\;\; f \neq 0 \;\text{ and }\; f(x) = 0$$

Now $S : R$ is said to be an **algebraic extension** iff any $x \in S$ is algebraic over R. Somewhat more restrictive: x is said to be **integral over** R iff there is a monic polynomial $m \in R[t]$ such that x is a root of this polynomial. Formally again

$$\exists\; m \in R[t] \;\;:\;\; \mathrm{lc}(m) = 1 \;\text{ and }\; m(x) = 0$$

Likewise $S : R$ is said to be an **integral extension** iff any $x \in S$ is integral over R. The set of all algebraic resp. integral elements of S is said to be the **algebraic closure** (resp. the **integral closure**) of R in S and will be denoted by

$$\begin{aligned} \operatorname{alg}(S:R) &:= \{\, x \in S \mid x \text{ is algebraic over } R \,\} \\ \operatorname{int}(S:R) &:= \{\, x \in S \mid x \text{ is integral over } R \,\} \end{aligned}$$

(8.26) Remark:
Let us take a closer look at the definition above - in other words this reads as: If $x \in S$ is an integral element of the ring extension, then there is a power $1 \leq n \in \mathbb{N}$ and elements $a_0, \ldots, a_{n-1} \in R$ such that

$$x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0 \;=\; 0$$

In particular: If $a \in R$, then we may take $m(t) := t - a \in R[t]$ to find $m(a) = a - a = 0$. Hence any $a \in R$ of course is integral over R, formally this is the inclusion

$$R\,1_S \;\subseteq\; \operatorname{int}(S:R)$$

If $x \in S$ is algebraic only, then this equation need not be monic, that is there is a power $1 \leq n \in \mathbb{N}$ and elements $a_0, \ldots, a_n \in R$ (as not all the a_k are allowed to be zero we may take $a_n \neq 0$) such that

$$a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0 \;=\; 0$$

If R is a field then we can divide the respective equation $f(x) = 0$ by the leading coefficient a_n of f. Hence - supposed R is a field - any algebraic extension already is integral. However if R is an integral domain only, then an algebraic extension need not be integral.

(8.27) Example:
Consider the ring extension $\mathbb{Q} : \mathbb{Z}$, then $1/2 \in \mathbb{Q}$ is algebraic over $\mathbb{Z}$, since it is a root of $f(t) = 2t - 1$. However $1/2$ is *not* integral over $\mathbb{Z}$. Suppose we had an equation of the form

$$\left(\frac{1}{2}\right)^n + \sum_{k=0}^{n-1} a_k \left(\frac{1}{2}\right)^k \;=\; 0$$

then multiplying this equation with 2^n and rearranging a little would yield the following equation, which cannot be true, since $2 \notin \mathbb{Z}^*$

$$1 \;=\; -\sum_{k=0}^{n-1} a_k 2^{n-k} \;=\; -2\sum_{k=0}^{n-1} a_k 2^{n-1-k} \;\in\; 2\mathbb{Z}$$

(8.28) Proposition: (viz. 1228)
Let $(Q,+,\cdot)$ and $(S,+,\cdot)$ be commutative rings and $P \leq_r Q$ and $R \leq_r S$ be a sub-rings of Q and S respectively. Also consider an epimorphism of rings $\pi : S \twoheadrightarrow Q$ such that $\varrho(R) \subseteq P$. If now $\star$ abbreviates any one of the words *integral*, *finitely generated* or *finite*, then we get the implication

$$S : R \text{ is } \star \implies Q : P \text{ is } \star$$

Nota In fact we will prove a little more: If $\{ s_i \mid i \in I \} \subseteq S$ generates S as an R-module (resp. R-algebra), then $\{ \pi(s_i) \mid i \in I \}$ generates Q as as a P-module (resp. P-algebra). In particular we find

$$[Q : P] \leq [S : R]$$

(8.29) Proposition: (viz. 1229)
Let $S : R$ be a ring extension and $\mathfrak{u} \trianglelefteq_i S$ be an ideal in the extension ring S. Then we obtain the following statements

(i) If $x \in \text{NZD}(S)$ is a non-zero divisor of S (that is $xy = 0$ implies $y = 0$) and x is integral over R, then there is a monic polynomial $m \in R[t]$ over R, such that $m(x) = 0$ and $m(0) \neq 0$.

(ii) If $S : R$ is an integral extension such that the structural homomorphism $\alpha : R \hookrightarrow S : a \mapsto a\,1_S$ is injective, then $\alpha(R^*) = S^*$. That is for any $a \in R$ we find [and in this case $\alpha(a)^{-1} = \alpha(a^{-1})$]

$$a \in R^* \iff \alpha(a) \in S^*$$

(iii) If $S : R$ is an integral extension and $\mathfrak{u} \cap R = 0$, then $\mathfrak{u}$ is contained in the zero-divisors of S. Formally that is the implication:

$$\mathfrak{u} \cap R = 0 \implies \mathfrak{u} \subseteq \text{ZD}(S)$$

(iv) If $S : R$ is an integral extension then the following ring extension is integral, as well (where the structural homomorphism, given by $\overline{\alpha} : a + \mathfrak{u} \cap R \mapsto \alpha(a) + \mathfrak{u}$, is injective)

$$S \big/ \mathfrak{u} : R \big/ \mathfrak{u} \cap R \text{ is integral}$$

(v) If $U \subseteq R$ is multipicatively closed, then we regard $U^{-1}S$ as an $U^{-1}R$-algebra, as in (3.123). If now $S : R$ is integral, then the ring extension $U^{-1}S : U^{-1}R$ is integral, as well (where the structural homomorphism, is given by $U^{-1}\alpha : a/u \mapsto (a\,1_S)/u = a/u\,1_{U^{-1}S}$)

$$U^{-1}S : U^{-1}R \text{ is integral}$$

(vi) If $(R,+,\cdot)$ is an integral domain and $f \in R[t]$ is a monic polynomial of degree $n := \deg(f) \geq 1$, then $R[t] : R[f]$ is a finite ring extension having the basis $\{ t^k \mid 0 \leq k < n \}$.

(8.30) Lemma: (viz. 1231)
Let $S : R$ be a ring extension. Then we find the following relations between the notions of a *finite*, *integral* or *algebraic* ring extension $S : R$ to be true:

(i) If $x \in S$ is an integral element over R, then $R[x] : R$ is finite. More precisely: If $m \in R[t]$ is a monic polynomial of degree $\deg(m) = n$ such that $m(x) = 0$, then $\{\, x^k \mid 0 \leq k < n \,\}$ is a generating set of $R[x]$ over R and hence $[R[x] : R] \leq n$.

(ii) If $x_1, \ldots, x_n \in S$ are finitely many elements of S, that are integral over R and $P := R[x_1, \ldots, x_n]$ is the intermediate ring generated by these elements, then $[P : R] < \infty$ is a finite extension.

(iii) If $S : R$ is a finite extension, then $S : R$ also is integral. More precisely: If $n = [S : R]$ then for any $x \in S$ there is some monic polynomial $m \in R[t]$ of degree $\deg(m) \leq n$ such that $m(x) = 0$.

(iv) If $S : R$ is a ring extension generated by integral elements, then the entire extension $S : R$ is integral. More precisely: If there is some $X \subseteq S$ such that any $x \in X$ is integral over S and we also have $S = R[X]$, then any $s \in S$ is integral over R.

(v) We find the equivalence: $S : R$ is a finite ring extension (i.e. there are finitely many $s_1, \ldots, s_k \in S$ such that $S = \mathrm{Lh}_R\{\, s_1, \ldots, s_k \,\}$), if and only if $S : R$ is integral and finitely generated (i.e. there are finitely many $x_1, \ldots, x_n \in S$ such that $S = R[x_1, \ldots, x_n]$)

(vi) If $S : R$ is any ring extension, then the set $\overline{R} := \mathrm{int}(S : R) \subseteq S$ of elements of S that are integral over R, is an intermediate ring $S : \overline{R} : R$ of $S : R$. And for this we get

$$\mathrm{int}\big(S : \overline{R}\big) \;=\; \overline{R}$$

(vii) If $S : E$ is any ring extension in which E is a field and $x \in S$ is an algebraic element over E, then $E[x]$ already is a field.

(viii) If $S : R$ is an integral ring extension, where $S \neq 0$ is a non-zero ring, then the following two combinations of properties or R and S are equivalent

(a) R is a field and S is an integral domain

(b) S is a field and S is a torsion-free R-module

Nota As S in (b) also is an integral domain, (8.1.(iii)) tells us that it suffices that the structural homomorphism $\alpha(a) = a\,1_S$ is injective. Then S already is a torsion-free R-module.

Nota If S in (b) is not torsion-free, then R in (a) need not be a field: As a counter-example just look at the ring extension $\mathbb{Z}_7 : \mathbb{Z}_{21}$ in which $\mathbb{Z}_7$ is a field, as $7 \in \mathbb{Z}$ is prime, but $\mathbb{Z}_{21}$ is not.

(ix) Let $S : R$ is any ring extension and denote $\overline{R} := \mathrm{int}(S : R)$ again. If now $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is an ideal of R and $x \in S$ an element of S, then we say that x is *integral over* $\mathfrak{a}$ iff there are some $n \geq 1$ and $a_0, \ldots, a_{n-1} \in \mathfrak{a}$ such that $x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0 = 0$. And thereby we get

$$\{\, x \in S \mid x \text{ is integral over } \mathfrak{a} \,\} \;=\; \sqrt{\mathfrak{a}\overline{R}}$$

(8.31) Lemma: (viz. 1234)
Let $(R,+,\cdot)$, $(S,+,\cdot)$ and $(T,+,\cdot)$ be commutative rings and $\alpha : R \to S$ and $\beta : S \to T$ be homomorphisms of rings. Then we regard $S : R$ and $T : S$ as ring extensions. Likewise $T : R$ is a ring extension induced by $\beta\alpha : R \to T$. Then the following statements are true:

(i) The property *finitely generated* is transitive, this is to say: If $S : R$ is finitely generated, say $S = R[s_1, \ldots, s_m]$ where $s_i \in S$ and $T : S$ is finitely generated, too, say $T = S[t_1, \ldots, t_n]$ where $t_j \in T$, then $T : R$ is finitely generated, by $T = R[\beta(s_i), \ldots, \beta(s_m), t_1, \ldots, t_n]$, as well.

(ii) If β is injective, then the following two statements (a) and (b) are equivalent: Nota if β is not injective, then we still retain (b) $\implies$ (a) and (a) $\implies$ $T : S$ is integral.

 (a) $T : R$ is integral

 (b) both $T : S$ and $S : R$ are integral

(iii) In the following two statements, we generally have (b) $\implies$ (a). If R is a PID and β is injective, then the statements (a) and (b) are equivalent:

 (a) $T : R$ is finite

 (b) both $T : S$ and $S : R$ are finite

(8.32) Theorem: (viz. 1259)
Lying-over Theorem: Let $S : R$ be any integral ring extension, with $S \neq 0$ and denote its structural homomorphism by $\alpha : R \to S$ with $\alpha(a) = a\,1_S$. Then all the following statements are true:

(i) As always $\Sigma := \operatorname{Spec}(\alpha)$ is well-defined. But since $S : R$ is integral, Σ even is surjective. That is for any prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ there is some prime ideal $\mathfrak{q} \trianglelefteq_{\mathrm{i}} S$, such that we get $\mathfrak{p} = \mathfrak{q} \cap R$

$$\Sigma \;:\; \operatorname{Spec}(S) \twoheadrightarrow \operatorname{Spec}(R) \;:\; \mathfrak{q} \mapsto \mathfrak{q} \cap R$$

And if S is a noetherian ring, then Σ only has finite fibres. That is for any prime ideal $\mathfrak{p} \in \operatorname{Spec}(R)$ the fibre $\Sigma^{-1}(\mathfrak{p}) \subseteq \operatorname{Spec}(S)$ is a finite set. Formally this can be put as

$$\forall\, \mathfrak{p} \in \operatorname{Spec}(R) \;:\; \#\{\, \mathfrak{q} \in \operatorname{Spec}(S) \mid \mathfrak{q} \cap R = \mathfrak{p} \,\} < \infty$$

(ii) The restriction $\Sigma : \operatorname{Smax}(S) \twoheadrightarrow \operatorname{Smax}(R)$ is well-defined and surjective, as well. In fact, for any prime ideal $\mathfrak{n} \in \operatorname{Spec}(S)$ we find that: $\mathfrak{n}$ is a maximal ideal of S, if and only if $\mathfrak{n} \cap R \trianglelefteq_{\mathrm{i}} R$ is a maximal ideal of R. Formally

$$\forall\, \mathfrak{n} \in \operatorname{Spec}(S) \;:\; \mathfrak{n} \text{ is maximal} \iff \mathfrak{n} \cap R \text{ is maximal}$$

(iii) The map Σ is somewhat weaker than injective: If $\mathfrak{u}$ and $\mathfrak{v} \trianglelefteq_{\mathrm{i}} S$ are any ideals, such that and one is contained in the other, but $\mathfrak{u} \cap R = \mathfrak{v} \cap R$ is identical and a prime ideal, then $\mathfrak{u}$ and $\mathfrak{v}$ already are equal, themselves:

$$\left.\begin{array}{ccc} \mathfrak{u} & \subseteq & \mathfrak{v} \\ \mathfrak{u} \cap R & = & \mathfrak{v} \cap R \end{array}\right\} \implies \mathfrak{u} = \mathfrak{v}$$

(iv) Let $\mathfrak{b} \trianglelefteq_i S$ be an arbitrary and $\mathfrak{q} \trianglelefteq_i S$ be a prime ideal, then $\mathfrak{b} \subseteq \mathfrak{q}$ is equivalent to $\mathfrak{b} \cap R \subseteq \mathfrak{q} \cap R$. Using $\mathbb{V}(\mathfrak{b}) := \{ \mathfrak{q} \in \mathrm{Spec}(S) \mid \mathfrak{b} \subseteq \mathfrak{q} \}$ this is the following identity of sets of prime ideals of R

$$\Sigma\big(\mathbb{V}(\mathfrak{b})\big) \quad = \quad \mathbb{V}\big(\mathfrak{b} \cap R\big)$$

Nota the $\mathbb{V}(\mathfrak{b})$ can be used as the closed set of a topology on the spectrum $\mathrm{Spec}(S)$, the so-called *Zariski-topology*. In this sense (iv) tells us, that Σ is a *closed* map with respect to the Zariski-topologies on the spectra $\mathrm{Spec}(R)$ and $\mathrm{Spec}(S)$.

(v) For any prime ideals $\mathfrak{p} \trianglelefteq_i R$ and $\mathfrak{q} \trianglelefteq_i S$ we get: If $\mathfrak{p} = \mathfrak{q} \cap R$ then $\mathfrak{p} = (\mathfrak{p}S) \cap R$ and $\mathfrak{q}$ is a minimal prime over $\mathfrak{p}S$. The latter is to say: $\mathfrak{p}S \subseteq \mathfrak{q}$ and for any $\mathfrak{q}' \in \mathrm{Spec}(S)$ we find that $\mathfrak{p}S \subseteq \mathfrak{q}' \subseteq \mathfrak{q}$ implies $\mathfrak{q}' = \mathfrak{q}$. Formally that is

$$\Sigma^{-1}(\mathfrak{p}) \quad \subseteq \quad \mathbb{V}\big(\mathfrak{p}S\big)_*$$

(8.33) Lemma: (viz. 1258)
Lemma of Gauss: Let $S : R$ be any ring extension and abbreviate $\overline{R} := \mathrm{int}(S : R)$. If now $p, q \in S[t]$ are monic polynomials, such that $pq \in \overline{R}[t]$, then $p, q \in \overline{R}[t]$ already.

(8.34) Remark:
Recall that we defined $(R, +, \cdot)$ to be a **normal domain** iff it is an integral domain, that is integrally closed in its quotient field $E := \mathrm{quot}(R)$. That is, the word "domain" refers to property (1), whereas "normal" refers to property (2) of

(1) R is an *integral domain*: $0 \neq 1$ and $\mathrm{zd}(R) = \{0\}$

(2) R is *integrally closed* in E: $\mathrm{int}(E : R) = R$

By now we have seen two situations, that guarantee R to be a normal domain: (i) Any UFD is a normal domain, by (2.65) and (ii) if R is an integral domain, then $\overline{R} := \mathrm{int}(E : R)$ is a normal domain, by (8.30.(vi)). And in this light the Lemma of Gauss (8.33) can be seen, as a generalization of (7.29.(x)). For a normal domain R it can be formulated as:

Lemma of Gauss: Let $(R, +, \cdot)$ be a normal domain and $E := \mathrm{quot}(R)$ its quotient field. If now $p, q \in E[t]$ are monic polynomials, such that $pq \in R[t]$, then $p, q \in R[t]$ already.

Norm and Trace
The following insight is as simple, as it is ingenious: As S in $S : R$ is an R-module and the multiplication on S is R-linear, we can look at the operations of R through the spectacles of linear algebra. This will become one of the cornerstones of Galois Theory that addresses the problem of solving polynomial equations.

(8.35) Remark:
If $S : R$ is a ring extension and $x \in S$, then we obtain an R-linear map on S by multiplication with x (from the left). That is the following map λ_x is an R-module endomorphism of S

$$\lambda_x \ : \ S \to S \ : \ u \mapsto xu$$

The additivity $\lambda_x(u+v) = \lambda_x(u) + \lambda_x(v)$ is due to the first identity in (M) of an R-semi-algebra and the R-linearity $\lambda_x(au) = a\lambda_x(u)$ is part of property (A), there. This map is the link between linear algebra and ring extensions, it will be used to define the characteristic and minimal polynomials of an element $x \in S$: If $f \in R[t]$ is any polynomial and x, $u \in S$, then is is clear that $f(\lambda_x)(u) = f(x)\,u$, as

$$f(\lambda_x)(u) \;=\; \left(\sum_{k=0}^{\infty} f[k]\lambda_x^k\right)(u) \;=\; \sum_{k=0}^{\infty} f[k]\,x^k u \;=\; f(x)\cdot u$$

In other words that is $f(\lambda_x)(u) = f(x)\,u = \lambda_{f(x)}(u)$ and hence $f(\lambda_x) = \lambda_{f(x)}$, as this is true for any $u \in S$. In particular we find that $f(\lambda_x) = 0 \in \mathrm{end}(M)$ is equivalent to $f(x) = 0 \in S$: If $f(\lambda_x) = 0$ then $0 = f(\lambda_x)(1) = f(x)\,1 = f(x)$ and vice versa. Let us emphasize this important equivalence

$$f(\lambda_x) \;=\; 0 \quad\Longleftrightarrow\quad f(x) \;=\; 0$$

Therefore the null ideal $\{\, f \in R[t] \mid f(\lambda_x) = 0 \,\}$ of λ_x is just the same as $\{\, f \in R[t] \mid f(x) = 0 \,\}$ the null ideal of x. In this sense the minimal polynomial of a ring-extension is just a special case of a minimal polynomial of an endomorphism. Nevertheless let us reformulate (5.42.(iii)) for this special case:

(8.36) Definition:
Consider a ring extension $S : R$ where R is an integral domain. For a fixed $x \in S$ we call the kernel $\mathfrak{v}_x$ of the evaluation homomorphism ε_x the **null ideal** of x

$$\varepsilon_x \;:\; R[t] \to S \;:\; f \mapsto f(x)$$

$$\mathfrak{v}_x \;:=\; \{\, f \in R[t] \mid f(x) = 0 \,\} \;\trianglelefteq_{\mathrm{i}}\; R[t]$$

Clearly x is algebraic over R if and only if $\mathfrak{v}_x \neq 0$. And a polynomial $m \in R[t]$ is said to be the **minimal polynomial** of x, iff it satisfies one of the following four equivalent properties. If such a polynomial exists, it is uniquely determined and we write $m_x := m$ again.

(a) The polynomial m satisfies: (1) m is monic, (2) $m(x) = 0$ and (3) for any $f \in R[t]$ we find that $f(x) = 0$ implies $m \mid f$.

(b) The polynomial m satisfies: (1) m is monic, (2) $m(x) = 0$ and (3) for any $f \in R[t]$ with $f \neq 0$ we find that $f(x) = 0$ implies $\deg(m) \leq \deg(f)$.

(c) The polynomial m satisfies: (1) m is monic and (2) m generates the null ideal of x, formally that is: $mR[t] = \{\, f \in R[t] \mid f(x) = 0 \,\}$.

(d) The polynomial m is the minimal polynomial of $\lambda_x \in \mathrm{end}(S)$, $\lambda_x(u) := xu$ in the sense of (5.41.(v)).

Nota As R is an integral domain, $\mathfrak{v}_x \in \mathrm{Spec}(R[t])$ is a prime ideal and if m is the minimal polynomial of x, then we get from (c), that $m \in R[t]$ already is a prime element of the polynomial ring. In short: If it exists, the minimal polynomial always is irreducible.

(8.37) Corollary: (viz. 1258)
Let $S : R$ be a ring extension, in which R is a normal domain. If now $x \in S$ is an element, that is integral over R, then it has has a minimal polynomial $m_x \in R[t]$.

(8.38) Definition:
Let $S : R$ be a finite ring extension, such that S is a free R-module. For any $x \in S$ we regard the homothety $\lambda_x : S \to S : y \mapsto xy$, which is an endomorphism of R-modules. Then we may define the **norm** and **trace** of x to be the determinant resp. trace of this endomorphism λ_x

$$\begin{aligned} N_{S:R}(x) &:= \det(\lambda_x) \\ T_{S:R}(x) &:= \mathrm{tr}(\lambda_x) \end{aligned}$$

Thereby $N_{S:R}$ and $T_{S:R}$ are maps of the form $S \to R$. And in complete analogy we define the **characteristic polynomial** of x to be the characteristic polynomial of λ_x, that is

$$c_x(t) := c_{\lambda_x}(t) = \det(t\mathbb{1}_S - \lambda_x) \in R[t]$$

Nota that both the determinant and trace of $\lambda_x \in \mathrm{end}(S)$ are independent of the specific ordered R-basis chosen for S, according to (4.43). And the same is true for the characteristic polynomial, due to (5.41.(ii)).

(8.39) Proposition: (viz. 975)
Let $S : R$ be a finite ring extension of degree $n := [S : R]$, such that S is a free R-module. Then $T_{S:R} : S \to R$ is R-linear and $N_{S:R} : S \to R$ is multiplicative, that is

$$\begin{aligned} T_{S:R}(ax) &= aT_{S:R}(x) \\ T_{S:R}(x+y) &= T_{S:R}(x) + T_{S:R}(x) \\ N_{S:R}(1_S) &= 1_R \\ N_{S:R}(ax) &= a^n N_{S:R}(x) \\ N_{S:R}(xy) &= N_{S:R}(x) \cdot N_{S:R}(y) \end{aligned}$$

for any $x, y \in S$ and $a \in R$. Also x satisfies its own characteristic polynomial, that is $c_x(x) = 0$ and the norm and trace of x occur as the coefficients $c_x[0] = (-1)^n N_{S:R}(x)$ and $c_x[n-1] = -T_{S:R}(x)$ in the characteristic polynomial of x. A little less formal that is

$$c_x(t) = t^n - T_{S:R}(x)t^{n-1} + \cdots + (-1)^n N_{S:R}(x)$$

(8.40) Example:

(i) Consider the field extension $\mathbb{C} : \mathbb{R}$ in its standard ordered basis $(1, i)$. As $i \cdot 1 = 1$ and $i \cdot i = -1$ the matrix representation of λ_i is given to be the following

$$[\lambda_i] \;=\; \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$$

In particular we find $T_{\mathbb{C}:\mathbb{R}}(i) = 0$ and $N_{\mathbb{C}:\mathbb{R}}(i) = 1$, likewise $c_i(t) = t^2 + 1$. This is an example of the property $c_i(i) = 0$ and as $i \notin \mathbb{R}$ we can also conclude $\mu_i(t) = t^2 + 1$.

(ii) More generally: If $S : R$ is any ring extension and $x \in S$ is integral over R, then $R[x] : R$ is a finite ring extension. Suppose x has a minimal polynomial m_x, that is m_x is the monic generator of the null ideal $\mathfrak{v}_x = \mathsf{kn}(f \mapsto f(x)) = \{\, f \in R[t] \mid f(x) = 0 \,\}$. Then

$$R[t] \,\big/\, m_x R[t] \;\xrightarrow{\sim}\; R[x] \;:\; f + m_x R[t] \mapsto f(x)$$

is an isomorphism of R-algebras, by the first isomorphism theorem. Now by (8.10.(i)) $R[x] : R$ has the ordered basis $(1, x, \ldots, x^{n-1})$ where $n := \deg(m_x)$. As $\lambda_x(x^k) = x^{k+1}$ for any $k < n$ and x^n can be expressed, as $x^n = -m_x[0] - m_x[1]x - \cdots - m_x[n-1]x^{n-1}$ we find the following matrix representation of λ_x in this ordered basis:

$$[\lambda_x] \;=\; \begin{pmatrix} 0 & 0 & \cdots & 0 & -m_x[0] \\ 1 & 0 & \cdots & 0 & -m_x[1] \\ 0 & 1 & \cdots & 0 & -m_x[2] \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 1 & -m_x[n-1] \end{pmatrix} \;=\; \mathsf{comp}(m_x)$$

Both, the characteristic and minimal polynomials of this matrix are m_x again, according to (5.43), even for an arbitrary commutative ring R. Formally that is

$$c_{[\lambda_x]}(t) \;=\; m_{[\lambda_x]}(t) \;=\; m_x(t)$$

8.4 Algebraic Dependence

If E is a field and V an E-vector-space, then V is of the form $V = E^{\oplus B}$ where B is some basis of V over E. And this completely defines the algebraic structure of V. If A is an F-algebra, then it also is an E-vector-space, but $A = E^{\oplus B}$ doesn't help much, as the multiplicative structure of A is not respected - just look at $A = E[t]$ for a counter-example.
Therefore we need a different approach. The standard-algebra is a polynomial ring $R[t_i \mid i \in I]$, so the question is: How large a polynomial ring is contained in A? This is quite similar to the question: How large a free module $R^{\oplus I}$ is contained (in the R-module) M?
In (3.102.(viii)) we found a satisfactory answer to this question, in case R is an integral domain: There is a maximal linearly independent subset $L \subseteq M$ and any two of these share the same cardinality. This is what we called the *linear freedom* of M. So M contains an isomorphic copy of $F = R^{\oplus L}$ as a sub-module. However M can be larger still, but the rest M/F is a torsion module.
This is very similar to what we will find for R-algebras A, too. If A is an integral domain and the structural homomorphism $\alpha : a \mapsto a1_A$ is injective, then A contains an isomorphic copy of a polynomial ring $P = R[t_i \mid i \in I]$ and the maximal size $|I|$ of this is uniquely determined - it will be called *transcendence degree* of A over R. Again A may be larger, but the rest $A : P$ is an algebraic extension.

This is an astounding similarity, but the analogy is even more far-reaching: In case R is a PID and M is a finitely generated R-module, then (5.32) gives a detailed description of the structure M can have $M = R^f \oplus \text{TOR}(M)$ and we can even control the torsion-part very accurately. In case E is a field and A is a finitely generated E-algebra, then the Noetherian normalisation theorem will be the analogue for A: $A : P$ will be a finite extension, where P is an isomorphic copy of $E[t_1, \ldots, t_n]$ and we can even arrange P according to a given chain of ideals.
So let us begin with this beautiful theory: The first part is fairly easy, we will study algebraic ring extensions and prove that (in integral domains) algebraic dependence is a dependence relation again, such that we can reap the harvest of section 3.6 a second time. It also is easy to formulate the Noetherian normalisation theorem. Its proof, however, is one of those technical monsters, that dwell out there. In case you really want to work through it, you have been warned.

(8.41) Proposition: (viz. 1245)

(i) Let $S : R$ be a ring extension, such that $\text{NIL}(R) = 0$ (we say R is *reduced*). Then for any element $x \in S$ the following two statements are equivalent

 (a) x is algebraic over R

 (b) there is some $a \in R$ with $a \neq 0$ and ax is integral over R

(ii) Let $S : R$ be a ring extension, such that R is an integral domain, then the algebraic closure of R in S is an intermediate ring of $S : R$, that is

$$R\,1_S \quad \subseteq \quad \text{alg}(S : R) \quad \leq_{\text{a}} \quad S$$

(iii) Let $(S,+,\cdot)$ be an integral domain and $R \leq_r S$ be a sub-ring of S, then we get the equivalence of

(a) $S : R$ is algebraic

(b) $\text{QUOT}(S) : \text{QUOT}(R)$ is algebraic

And in this case we also get: Let us denote $U := R \setminus \{0\}$ such that $\text{QUOT}(R) = U^{-1}R$. Then we obtain a canonical isomorphism of the quotient field $\text{QUOT}(S)$ of S

$$U^{-1}S \xrightarrow{\sim} \text{QUOT}(S) \; : \; \frac{s}{u} \mapsto \frac{s}{u}$$

(iv) *Transitivity of being algebraic*: Let $(T,+,\cdot)$ be an integral domain and $S \leq_r T$ and $R \leq_r S$ be sub-rings of T. Then the following two statements are equivalent

(a) $T : R$ is algebraic

(b) $T : S$ and $S : T$ are algebraic

(v) *Artin-Tate-Lemma:* Let $T : R$ be a ring extensions and S be an intermediate ring $T : S : R$, such that (1) R in noetherian, (2) $T : R$ is finitely generated and (3) $T : S$ is finite. Then $S : R$ is finitely generated ring extension, too.

(8.42) Remark:
In (8.30.(vi)) we have seen, that the integral closure $\text{int}(S : R)$ of R in S is a ring again. If R is a field, then we have $\text{alg}(S : R) = \text{int}(S : R)$, such that the algebraic closure $\text{alg}(S : R)$ is a ring, as well. But we have just seen, that it suffices that R is an integral domain, for $\text{alg}(S : R)$ to be a ring, once more. However, for general R the algebraic closure need not be a sub-ring of S!

As an example let $R := \mathbb{Z}^2$ and $S := \mathbb{Z}[x]^2$. Then $(x,0) \in S$ is algebraic over R, as $(0,1) \cdot (x,0) = (0,0)$. Likewise $(0,x)$. However the sum $(x,0) + (0,x) = (x,x)$ is not algebraic over R as any polynomial $(f,g) \in R[t]$ turns (x,x) into $(f,g)(x,x) = (f(x),g(x))$ which only is zero, if both f and g are.

(8.43) Remark: (viz. 1257)
If $T : S$ and $S : R$ are ring extensions, such that $T : R$ is *integral* or *algebraic*, then $T : S$ and $S : R$ are integral resp. algebraic again (under reasonable assumptions). The same is true for *finite* (under quite strong assumptions). The converse implications are generally true. Also if $T : S$ and $S : R$ are *finitely generated*, say $T = S[y_1,\ldots,y_n]$ and $S = R[x_1,\ldots,x_m]$, then $T = R[x_1,\ldots,x_m,y_1,\ldots,y_n]$ such that $T : R$ is finitely generated again. The converse need not be true however: If $T : R$ is finitely generated, then $S : R$ need not be, even in extremely nice cases:

- Let $(R,+,\cdot)$ be a field and $B := E[x,y]$ the polynomial ring in two variables over E. Then we define A to be the sub-algebra of B generated by elements of the form xy^k where $k \in \mathbb{N}$. That is

$$A \; := \; E[xy^k \mid k \in \mathbb{N}]$$

- We then find $xx^kA \subseteq xy^kE + x^2y^kB$. Thereby we are able to construct ideals $\mathfrak{a}_k \trianglelefteq_\mathrm{i} A$ with the property $xx^{y+1} \notin \mathfrak{a}_k$. For these ideals we take

$$\mathfrak{a}_k \;:=\; \sum_{j=0}^{k} xy^jA$$

 Then it is clear that these ideals for an ascending chain and as $xy^{k+1} \notin \mathfrak{a}_k$ the inclusions of these chain even are strict: $\mathfrak{a}_0 \subset \mathfrak{a}_1 \subset \ldots \subset \mathfrak{a}_k \subset \ldots$.

- In particular A is not a noetherian ring. So it cannot be finitely generated: If it was then (as E is a field) the Hilbert basis theorem (2.42) would imply, that A is noetherian - which it is not. Thus there is an infinitely generated E-algebra A inside an E-algebra B, that is generated by 2 elements! This counter-example is sharp however, as we see in the proposition below.

- $(\diamondsuit)$ Clearly $\{ x, y \}$ is a transcendence basis of $B : E$. We also find a transcendence basis $\{ x, xy \}$ of $A : E$, so this does not contradict the properties of transcendence bases and the transcendence degree, that will be introduced in the next section.

- **Proposition:** Let $(E, +, \cdot)$ is a field and B be an E-algebra, that is generated by a single element, say $B = E[b]$ for some $b \in B$. If then $A \leq_\mathrm{a} B$ is a sub-algebra of B, then A is finitely generated.

(8.44) Definition:
Consider a ring extension $S : R$, (i.e. S is a commutative, unital R-algebra). Then for any element $x \in S$ and any subset $U \subseteq S$ we define the following notions

(i) Let us introduce a relation $\vdash$ between subsets $U \subseteq S$ and elements $x \in S$ of S: We say x is **algebraically dependent on** U, and write this as $U \vdash x$, iff there is a non-zero polynomial f over $R[U]$ such that $f(x) = 0$, formally that is

$$\exists f \in R[U][t] \;:\; f \neq 0 \;\text{ and }\; f(x) = 0$$

(ii) A finite subset $U = \{ u_1, \ldots, u_n \} \subseteq S$ is said to be **algebraically independent** iff for any polynomial $f \in R[t_1, \ldots, t_n]$ with the same number n of variables, we get the implication

$$f(u_1, \ldots, u_n) \;=\; 0 \quad\Longrightarrow\quad f \;=\; 0$$

 And an arbitrary subset $U \subseteq S$ is said to be **algebraically independent**, iff any finite subset of U is algebraically independent in the sense of finite sets. Of course U is said to be **algebraically dependent**, iff it is not algebraically independent.

(iii) Now a subset $U \subseteq S$ will be called a **transcendence basis** of S over R, iff it is algebraically independent and $S : R[U]$ is an algebraic extension (that is, iff any $x \in S$ satisfies $U \vdash x$).

(8.45) Lemma: (viz. 1247)
Let $S : R$ be a ring extension, such that S is an integral domain and the structural homomorphism $\alpha : a \mapsto a1_S$ is injective. Also let $x \in S$ be any element and $U \subseteq S$ be any subset of S, then the following statements are true

(i) The following four properties concerning U and x are equivalent

(a) $U \vdash x$

(b) $x \in \mathrm{alg}(S : R[U])$

(c) $ax \in \mathrm{int}(S : R[U])$, for some $a \in R$ with $a \neq 0$

(d) $R[U \cup \{ x \}] : R[U]$ is an algebraic ring extension

(ii) $\vdash$ is a dependence relation

(iii) If $U \subseteq S$ is algebraically independent, then the following two statements are equivalent:

(a) $U \vdash x$

(b) $U \cup \{ x \}$ is algebraic dependent (over R)

(iv) If $U = \{ u_1, \ldots, u_n \}$ is a finite set, then the following three statements are equivalent:

(a) $\{ u_1, \ldots, u_n \}$ is algebraically independent

(b) $\forall k \in 1 \ldots n$ we get $U \setminus \{ u_k \} \nvdash u_k$

(c) $\forall k \in 1 \ldots n$ we get $\{ u_1, \ldots, u_{k-1} \} \nvdash u_k$

(8.46) Corollary: (viz. 1250)
Let $S : R$ be a ring extension, such that S is an integral domain and the structural homomorphism $\alpha : a \mapsto a1_S$ is injective. Then the relation $\vdash$ of algebraic dependence is a dependence relation, by (8.45.(ii)) and therefore we get the following statements

(i) If $U \subseteq S$ is any subset, then the following three statements are equivalent

(a) U is $\vdash$independent

(b) U is algebraically independent

(c) $R[t_u \mid u \in U] \xrightarrow{\sim} R[U] : t_u \mapsto u$ is an isomorphism of R-algebras

(ii) For any subset $U \subseteq S$ we have $\langle U \rangle = \mathrm{alg}(S : R[U])$, in particular equivalent are

(a) U $\vdash$generates S

(b) $S : R[U]$ is an algebraic ring extension

(iii) If $U \subseteq S$ is any subset, then the following two statements are equivalent

(a) U is a $\vdash$basis of S

(b) U is a transcendence basis of $S : R$

(iv) *Basis Exchange Theorem:* Let V be a transcendence basis of $S : R$ and consider any subset $U \subseteq V$. Also let $U' \subseteq S$ be some subset, such that (1) U' is algebraically independent, (2) $R[U'] \subseteq R[U]$ is a sub-ring and (3) $R[U] : R[U']$ is an algebraic extension. Then also the following set

$$\big(V \setminus U\big) \cup U' \quad \text{is a transcendence basis of } S : R$$

(8.47) Remark:
Let $S : R$ be a ring extension, such that S is an integral domain and the structural homomorphism $\alpha : a \mapsto a1_S$ is injective. Then we can reap the harvest from (8.45.(ii)) and (8.46) by importing the properties of dependence relations for algebraic dependence. For convenience let us restate the major theorems in (3.57) in the language of algebraic dependence:

(i) If $U \subseteq S$ is algebraically independent and $W \subseteq S$ is a subset, such that $S : R[W]$ is algebraic, then there is some V with $U \subseteq V \subseteq W$, such that V is a transcendence basis of $S : R$. In particular any such ring extension $S : R$ has a transcendence basis.

(ii) If U and $V \subseteq S$ both are transcendence bases of $S : R$ then they are of the same cardinality $|U| = |V|$. This enables us to name the cardinality of any (and hence all) transcendence basis of $S : R$ the **transcendence degree** of $S : R$

$$\operatorname{trdeg}(S : R) \;:=\; |U|$$

(iii) If $U \subseteq S$ is any subset, then we get: (1) If U is algebraically independent, then $|U| \leq \operatorname{trdeg}(S : R)$ and (2) if $S : R[U]$ is algebraic, then $|U| \geq \operatorname{trdeg}(S : R)$.

(iv) If $U \subseteq S$ is a transcendence basis of $S : R$, such that $\operatorname{trdeg}(S : R) = |U| < \infty$ is finite and $V \subseteq S$ is another algebraically independent set in S, then we have the equivalence of

(a) $|V| = \operatorname{trdeg}(S : R)$

(b) V is a transcendence basis of $S : R$

(8.48) Example: (viz. 1251)

(i) If $S : R$ is an algebraic extension then $\emptyset \subseteq S$ is a transcendence basis of $S : R$ [$\emptyset$ is algebraically independent and $R[\emptyset]$]. The converse is true as well and hence we have

$$\operatorname{trdeg}(S : R) \;=\; 0 \quad\Longleftrightarrow\quad S : R \text{ is algebraic}$$

(ii) If $(R, +, \cdot)$ is an integral domain and $S = R[t_i \mid i \in I]$ is a polynomial ring over R, then the set $T := \{\, t_i \mid i \in I \,\}$ clearly is a transcendence basis of $S : R$, we even have $S = R[T]$. In particular

$$\operatorname{trdeg}\big(R[t_i \mid i \in I] : R\big) \;=\; |I|$$

(iii) If $(R, +, \cdot)$ is an integral domain and $E := \operatorname{QUOT}(R)$ its quotient field, then $E : R$ is an algebraic extension, as any $a/b \in E$ satisfies a polynomial $bt - a \in R[t]$ of degree 1. Therefore

$$\operatorname{trdeg}\big(\operatorname{QUOT}(R) : R\big) \;=\; 0$$

(iv) A special case of (8.49.(i)) below is the field of rational functions $F = E(t_1, \ldots, t_n)$ over a field $(E, +, \cdot)$. This is the quotient field of of the polynomial ring $E[t_1, \ldots, t_n]$. We then find, that the set $\{\, t_1, \ldots, t_n \,\} \subseteq F$ is a transcendence basis of $F : E$, as well.

(v) Let $(R,+,\cdot)$ be an integral domain and $S = R[t_1,\ldots,t_n]$ be the polynomial ring, in finitely many variables. By (ii) $\{\, t_1,\ldots,t_n \,\}$ is a transcendence basis of $S : R$. Let $s_1,\ldots,s_n \in S$ be the symmetric polynomials in n variables. Then by (7.67.(iii)) $\{\, s_1,\ldots,s_n \,\}$ is algebraically independent, too. Now (8.47.(iv)) tells us, that $\{\, s_1,\ldots,s_n \,\}$ is a transcendence basis of S, too. That is

$$R[t_1,\ldots,t_n] : R[s_1,\ldots,s_n] \text{ is algebraic}$$

Note that the algebra of symmetric polynomials $R[s_1,\ldots,s_n]$ is smaller than the polynomial ring $R[t_1,\ldots,t_n]$ itself, but the transcendence degrees over R are equal.

(vi) Let $(R,+,\cdot)$ be an integral domain and $A := R[t_1,\ldots,t_n]$ be the polynomial ring in n variables. If now $p \in A$ is a prime polynomial, with $\deg_1(p) \geq 1$, then we take

$$S \;:=\; {}^{A}\Big/_{p\,A}$$

for the extension ring of R. Now define $u_k := t_k + fA \in S$ and $U := \{\, u_2,\ldots,u_n \,\}$, then U is a transcendence basis of $S : R$ and in particular we have

$$\operatorname{trdeg}(S : R) \;=\; n-1$$

(vii) Let $(S,+,\cdot)$ be an integral domain, $R \leq_{\mathrm{r}} S$ be a sub-ring and $U \subseteq S$ be a transcendence basis of $S : R$. For any $u \in U$ pick up a power $1 \leq m(u) \in \mathbb{N}$. Then the set $U' := \left\{\, u^{m(u)} \mid u \in U \,\right\}$ is a transcendence basis of $S : R$, as well.

(8.49) Proposition: (viz. 1252)
Let $(S,+,\cdot)$ be an integral domain and $R \leq_{\mathrm{r}} S$ and $Q \leq_{\mathrm{r}} R$ be sub-rings of S. Then the following three statements are true

(i) Let $1 \leq n \in \mathbb{N}$ and $V = \{\, v_1,\ldots,v_n \,\} \subseteq S$ be a transcendence basis of $S : R$ $n \geq 1$) and $A = (a_{i,j}) \in \operatorname{mat}_n(R)$ be an $(n \times n)$-matrix. For any $i \in 1\ldots n$ define $w_i = [Au]_i = \sum_j a_{i,j}u_i$. Then the following two statements are equivalent

(a) $\det(A) = 0$

(b) $\{\, w_1,\ldots,w_n \,\}$ is a transcendence basis of $S : R$

(ii) If $V \subseteq S$ is a transcendence basis of $S : R$, then $V/1 := \{\, v/1 \mid v \in V \,\} \subseteq F$ is a transcendence basis of the extension of the quotient fields $\textsc{quot}(S) : \textsc{quot}(R)$ and therefore we have

$$\operatorname{trdeg}\big(\textsc{quot}(S) : \textsc{quot}(R)\big) \;=\; \operatorname{trdeg}\big(S : R\big)$$

(iii) If $U \subseteq R$ is a transcendence basis of $R : Q$ and $V \subseteq S$ is a transcendence basis of $S : R$ again, then $U \cap V = \emptyset$ and $U \cup V$ is a transcendence basis of $S : Q$. In particular we have

$$\operatorname{trdeg}\big(S : Q\big) \;=\; \operatorname{trdeg}\big(S : R\big) + \operatorname{trdeg}\big(R : Q\big)$$

(8.50) Remark: (viz. 1254)
In the above we always required S to be an integral domain. This is due to the fact, that we needed the transitivity of algebraic extensions and that the algebraic closure is a sub-ring again - refer to (8.41). This is not needed with *integral* instead of *algebraic*. So the above statements can often be modified, in case $S : R[U]$ is integral. And sometimes S being integral is not needed at all. Here are a few examples of such statements:

(i) If $S : R$ is any ring extension, then a subset $U = \{ u_1, \ldots, u_n \} \subseteq S$ is algebraically independent, if and only if the evaluation homomorphism $\varepsilon : R[t_1, \ldots, t_n] \twoheadrightarrow R[U] : f \mapsto f(u_1, \ldots, u_n)$ is an isomorphism of R-algebras.

Nota that this has far-reaching consequences: If R is an integral domain, then the polynomial ring $R[t_1, \ldots, t_n]$ is an integral domain, too (7.12.(vii)). Hence $R[U]$ is an integral domain, due to the isomorphy in (i). Likewise, if R is noetherian and U is finite, then $R[U]$ is noetherian again (2.42). Finally, if R is an UFD, then $R[U]$ inherits being an UFD, as well (7.29.(viii)).

(ii) Let $S : R$ be any ring extension and let $U, V \subseteq S$ such that U is an algebraically independent set. Then the following two statements are equivalent

 (a) $U \cup V$ is algebraically dependent over R

 (b) There is some $v \in V$ such that v is algebraically dependent over $R[U \cup V \setminus \{ v \}]$.

(iii) If $S : R$ is any ring extension and $U \subseteq S$ is algebraically independent over R, then there is some subset $U^* \subseteq S$, such that (1) $U \subseteq U^*$, (2) U^* is algebraically independent over R, too and (3) $S : R[U^*]$ is an algebraic extension of rings.

(iv) Let $S : R$ be any ring extension and $V \subseteq S$ be a subset, such that $S : R[V]$ is integral. Also let $U \subseteq V$ and $U' \subseteq S$ be subsets, such that (1) $R[U'] \subseteq R[U]$ and (2) $R[U] : R[U']$ is integral. Then $S : R[V']$ is integral, too, where $V' := (V \setminus U) \cup U'$.

(v) Let $S : R$ be any ring extension and $V \subseteq S$ be algebraically independent set. Also let $U \subseteq V$ and $U' \subseteq S$ be subsets, such that (1) U' is algebraically independent and (2) $R[U'] \subseteq R[U]$ Then $V' := (V \setminus U) \cup U'$ is algebraically independent, too.

Noetherian Normalisation
We will now aim for the Noetherian normalisation theorem, the structure theorem for finitely generated, commutative algebras A over a field E. It refines the theory of transcendence bases in two ways, as it contains the existence of an algebraically independent set $\{ z_1, \ldots, z_n \} \subseteq A$ (1) even if A is not an integral domain and (2) such that for $P = E[z_1, \ldots, z_n]$ the extension $A : P$ is finite, not only algebraic. It will be crucial for dimension theory, e.g. when proving that in (a finitely generated algebra A, that also is an integral domain) all maximal chain of prime ideals have the same length.
In order to put the proof into a readable form we chose to export a special case, as a separate proposition. Of course we already know, that a non-zero polynomial $0 \neq g \in E[t_1, \ldots, t_n]$ can be appended to a transcendence basis $\{ g, z_2, \ldots, z_n \}$, as this is a property of dependence relations. The proposition however is computational and will be the staging area to get $A : P$ finite.

(8.51) Proposition: (viz. 1261)
Let $(E,+,\cdot)$ be a field and consider $A := E[t_1,\ldots,t_n]$ a polynomial ring in $n \geq 1$ variables. If now $g \in A$ is a polynomial with, with $\deg(g) \geq 1$, then there are some $1 \leq m_2,\ldots,m_n \in \mathbb{N}$ such that for $z_i := t_i - t_1^{m_i} \in A$ (where $i \in 2\ldots n$) and $P := E[g,z_2,\ldots,z_n]$ we get

(1) $\{ g,z_2,\ldots,z_n \} \subseteq A$ is algebraically independent

(2) $A : P$ is a finite ring-extension, where $P := E[g,z_2,\ldots,z_n]$

(3) The ideal gP is prime in P and satisfies $gA \cap P = gP$

Nota In case $n = 1$ we do not need z_2 to z_n and the statements reduce to (1) g is not algebraic over E [which is clear, as $\deg(f(g)) = \deg(f) \cdot \deg(g)$], (2) $A : E[g]$ is a finite ring-extension [which is clear, as t_1 is algebraic over P, as $g(t_1) - g = 0$] and (3) gP is prime in P and $gA \cap P = gP$ [this has to be proved].

Nota The proof relies on (7.57) to get the z_i. If E is an infinite field, then the same proposition tells us, that we could have chosen the z_i in another way, too: There are non-zero $0 \neq a_2,\ldots,a_n \in E$, such that $z_i = t_i - a_i t_1$ the $\{ g,z_2,\ldots,z_n \}$ is another algebraically independent set satisfying properties (1) to (3).

(8.52) Theorem: (viz. 1263)
Noetherian Normalisation Theorem: Let $(E,+,\cdot)$ be a field and $A \neq 0$ be a finitely generated E-algebra. Also consider a chain $\mathfrak{a}_1 \subseteq \mathfrak{a}_2 \subseteq \ldots \subseteq \mathfrak{a}_r \trianglelefteq_{\mathrm{i}} A$ of proper ideals in A, that is $\mathfrak{a}_r \neq A$, of length $r \in \mathbb{N}$. Then there are elements $z_1,\ldots,z_n \in A$ and numbers $0 \leq k(1) \leq k(2) \leq \cdots \leq k(r) \leq n$ such that

(1) $\{ z_1,\ldots,z_n \} \subseteq A$ is algebraically independent

(2) $A : P$ is a finite ring-extension, where $P := E[z_1,\ldots,z_n]$

(3) For any $i \in 1\ldots r$ we have $\mathfrak{a}_i \cap P = z_1 P + \cdots + z_{k(i)} P$

Nota By (8.30.(v)) the ring-extension $A : P$ also is integral and hence algebraic. Therefore due to (1) and (2) $\{ z_1,\ldots,z_n \}$ is a transcendence basis of $A : E$. In case A also is an integral domain, this means that n is fixed to be $n = \mathrm{trdeg}(A : E)$ because of (8.47.(ii)).

Nota Under these assumptions A is a noetherian ring, by the Hilbert basis theorem (2.42). And because of (1) P is isomorphic to a polynomial ring in n variables over a field, by (8.50.(i)). In particular P is a noetherian UFD and therefore A also is a noetherian P-module, as we have (2) and (3.111.(vi)).

Nota As $\{ z_1,\ldots,z_n \}$ is algebraically independent, P is isomorphic to a polynomial ring $E[t_1,\ldots,t_n]$. Thereby $\mathfrak{a}_i \cap P$ corresponds to the ideal $\langle t_1,\ldots,t_{k(i)} \rangle_{\mathrm{i}} \trianglelefteq_{\mathrm{i}} E[t_1,\ldots,t_n]$ and therefore is prime in P

$$\{ \mathfrak{a}_i \cap P \mid i \in 1\ldots r \} \quad \subseteq \quad \mathrm{Spec}(P)$$

Nota This theorem will be continued in (8.76.(iii)). There we will prove that the numbers n and (in case A is an integral domain) $k(i)$ are uniquely determined to be $n = \mathrm{kdim}(A)$ and $k(i) = \mathrm{height}(\mathfrak{a}_i)$.

8.5 Algebraically closed Fields

In this section we will study field extensions and algebraically closed fields. The latter are a very rare but incredibly powerful fields in which any non-constant polynomial always has all its roots. As such these fields can no longer be extended algebraically, a true extension has to be transcendental. While few fields are algebraically closed, to begin with, any field admits an algebraic extension that is algebraically closed. E.g. the reals $\mathbb{R}$ are contained in the algebraically closed field $\mathbb{C}$ of complex numbers.
One of the major benefits of algebraically closed fields F is that any point of F^n corresponds to a maximal ideal of the polynomial ring $F[t_1,\dots,t_n]$. This has far reaching consequences: From this we find that algebraic sets (which are objects of geometry) correspond to radical ideals of $F[t_1,\dots,t_n]$ (which are objects of algebra). This gives birth to the entirely new branch of algebraic geometry, which studies geometric objects through the looking glass of its algebraic counterparts. These correspondences will all be formulated and proved in this section.

(8.53) Definition:
Recall that we speak of a ring extension $F : E$, if F is a unital E-algebra. We now define a **field extension** $F : E$ to be a ring extension, such that both, E and F, are fields. In this case a subset $P \subseteq F$ is said to be an **intermediate field** of $F : E$ - which we denote by $F : P : E$ - iff P is a subalgebra and a subfield of F. That is $P \leq_r F$ is a subring of F that also satisfies the properties

(1) for any $p \in P$ with $p \neq 0$ we get $p^{-1} \in P$

(2) for any $a \in E$ and any $p \in P$ we get $ap \in P$

In a field extension $F : E$ clearly F is an E-vector space (and in particular a torsion free E-module). Therefore the structural homomorphism $\alpha : E \hookrightarrow F : a \mapsto a1_F$ is injective and its image $\mathrm{im}(\alpha) = E\,1_F$ is an intermediate field of $F : E$

$$E\,1_F \;=\; \{\, a1_F \mid a \in E \,\}$$

Prob If $a1_F = b1_F$ we have $d1_F = 0_F$ for $d := a - b$. If we had $d \neq 0$, then $1_E = d^{-1}d$ such that $1_F = 1_E1_F = d^{-1}d1_F = d^{-1}0_F = 0_F$, which contradicts $F \neq 0$. Thus we have $a = b$, which is the injectivity of α. As α is a homomorphism of E-algebras, its image $E\,1_F$ is a subalgebra of F. Also, as $a1_F \neq 0_F$ implies $a \neq 0_E$ we get $(a1_F)^{-1} = a^{-1}1_F \in E\,1_F$, such that $E\,1_F$ also is a subfield of F.

(8.54) Remark:
If $F : E$ is a field extension and $U \subseteq F$ is a subset, then by (1.52) there is a sub-field $E \cup U$. We denote this intermediate field of $F : E$, that is generated by U by the symbol

$$E(U) \;:=\; \langle E \cup U \rangle_f \quad \leq_f \quad F$$

By (1.55) the intermediate field generated by U consists precisely of the quotients $f/g := fg^{-1}$ of elements $f, g \in E[U]$ of the intermediate ring generated by U. Yet by (8.4) the intermediate ring $E[U]$ consists of all polynomial expressions in finitely many elements of U over E. So combining these results we get an explicit description of $E(U)$ to be

$$E(U) \;=\; \left\{ fg^{-1} \mid f,g \in E[U],\, g \neq 0 \right\}$$

$$= \left\{ \frac{f(u_1,\ldots,u_n)}{g(u_1,\ldots,u_n)} \;\middle|\; \begin{array}{l} 1 \leq n \in \mathbb{N}, u_1,\ldots,u_n \in U \\ f,g \in R[t_1,\ldots,t_n], \\ g(u_1,\ldots,u_n) \neq 0 \end{array} \right\}$$

(8.55) Definition: (viz. 1268)
Let $(F,+,\cdot)$ be a field, then F is said to be **algebraically closed**, iff it satisfies one (and hence all) of the following six equivalent properties

(a) If $K:F$ is any field extension, then $\mathrm{alg}(K:F) = F1_K$.

(b) If K is a field such that $K:F$ is an algebraic field extension, then $K = F1_K$.

(c) If K is a field such that $K:F$ is a finite field extension, then $K = F1_K$.

(d) Any non-constant polynomial splits into linear factors over F. That is for any $f \in F[t]$ of degree $n := \deg(f) \geq 1$, there are some $a \in F$ and $x_1,\ldots,x_n \in F$ such that we get the following identity

$$f \;=\; a\prod_{i=1}^{n}(t-x_i)$$

(e) Any non-constant polynomial over F has a root in F, that is: If $f \in F[t]$ is of $\deg(f) \geq 1$, then there is some $x \in F$, such that $f(x) = 0$.

(f) If $p \in F[t]$ is an irreducible polynomial, then $\deg(p) = 1$

By (7.79.(iii)) the field $\mathbb{C}$ of complex numbers is algebraically closed. But the proof is analytic in nature and relies on the fact that every real polynomial of odd degree has a root. Also it is rather intricate and for this reason we will give an alternate proof in section 8.6. What we aim for next, is to prove that any field E is contained in an algebraically closed field. In fact this field uniquely determined (up to isomorphy) and hence called the *algebraic closure* of E. The following corollary will be vastly generalized in (8.59.(iii)), but only by using much more powerful tools.

(8.56) Corollary: (viz. 1269)
In any field $(F,+,\cdot)$ the maximal ideals of the polynomial ring $F[t]$ are precisely the principal ideals induces by irreducible polynomials. Formally this is the identity

$$\mathrm{Smax}\big(F[t]\big) \;= \{\, pF[t] \mid p \in F[t] \text{ irreducible} \,\}$$

Hence, if F is algebraically closed, then the maximal ideals of $F[t]$ are precisely the principal ideals induced by polynomials of the form $t-a \in F[t]$ for some $a \in F$. Formally again

$$\mathrm{Smax}\big(F[t]\big) \;= \{\, (t-a)F[t] \mid a \in F \,\}$$

Lemma von Steinitz: Konstruktion des algebraischen Abschlusses

(8.57) Proposition: (viz. 1269)

(i) If $(R,+,\cdot)$ is any commutative ring and $(A,+)$ is any monoid, then the cardinality of the polynomial ring $R[t \mid A]$ is the maximal cardinality of R and A. Formally that is

$$|R[t \mid A]| \;=\; \max\{\,|R|, |A|\,\}$$

(ii) If $(R,+,\cdot)$ is any commutative ring and $I \neq \emptyset$ is any non-empty set, then the cardinality of polynomial ring $R[t_i \mid i \in I]$ is given to be the maximal cardinality if $\mathbb{N}$, A and R:

$$|R[t_i \mid i \in I]| \;=\; \max\{\,|\mathbb{N}|, |R|, |I|\,\}$$

NOTA The main task here lies in proving $|\mathbb{N}^{\oplus I}| = \max\{\,|\mathbb{N}|, |I|\,\}$, the rest is then clear by (i). Though this is generally true, we did not formulate this identity as a separate proposition.

(iii) Let $S : R$ be an algebraic ring extension in which $(S,+,\cdot)$ is an integral domain. Then the cardinality of S cannot exceed that of $\mathbb{N}$ and R, since

$$|S| \;\leq\; \max\{\,|\mathbb{N}|, |R|\,\}$$

(iv) If $(E,+,\cdot)$ is any field, $P := \text{PRF}(E)$ its prime field and $F := \text{AC}(E)$ its algebraic closure. Then we have the following identity for the transcendence degree of $F : P$

$$|F| \;=\; \max\{\,|\mathbb{N}|, \text{trdeg}(F : P)\,\}$$

(v) If $(R,+,\cdot)$ is a commutative noetherian ring, $I \neq \emptyset$ is any non-empty set and $\mathfrak{a} \trianglelefteq_{\text{i}} R[t_i \mid i \in I]$ is an ideal in the polynomial ring, then we get: (1) If I is finite, then there is a finite subset $A \subseteq R[t_i \mid i \in I]$ such that $\mathfrak{a} = \langle A\rangle_{\text{i}}$. And (2) if I is infinite, then there is a subset $A \subseteq R[t_i \mid i \in I]$ such that $\mathfrak{a} = \langle A\rangle_{\text{i}}$ and $|A| \leq |I|$.

Hilbert's Nullstellensatz

Fix any commutative ring $(R,+,\cdot)$, a non-empty index set I and let $A := R[t_i \mid i \in I]$ be the polynomial ring $R[\mathbb{N}^{\oplus I}]$ over R in the variables t_i where $i \in I$. Recall that the evaluation $f(x)$ of a polynomial $f \in A$ in a point $x = (x_i) \in R^I$ - introduced in (7.52) - is well-defined. By construction A is a commutative R-algebra and the set $\text{ahom}(A,R)$ of R-algebra homomorphisms from A to R becomes a commutative algebra under the point-wise operations of functions from A to R. As $\varepsilon_x : f \mapsto f(x)$ is a homomorphism of R-algebras, we obtain a map from R^I to $\text{ahom}(A,R)$ by virtue of

$$R^I \;\to\; \text{ahom}(A,R) \;:\; x \;\mapsto\; \varepsilon_x$$

$$\varepsilon_x \;:\; A \to R \;:\; f \;\mapsto\; f(x)$$

And thereby the kernel $\mathfrak{m}_x := \text{kn}(\varepsilon_x) \trianglelefteq_{\text{i}} A$ is an ideal in A and if R is a field, it even is a maximal ideal of A. As in (7.60), for any subset $X \subseteq R^I$, we define the the *vanishing ideal* $\mathbb{I}(X)$ of X to be the set of all polynomials whose zero-locus contains X, that is

$$\mathbb{I}(X) \;:=\; \{\, f \in A \mid \forall\, x \in X : f(x) = 0\,\} \;=\; \bigcap_{x \in X} \mathfrak{m}_x$$

Likewise for a set $P \subseteq A$ of polynomials we denote the *algebraic set* $\mathbb{V}(P)$ of P to consist of those points, that belong to the zero locus of all the polynomials of P, that is

$$\mathbb{V}(P) := \left\{ x \in R^I \mid \forall f \in P : f(x) = 0 \right\} = \bigcap_{f \in P} \mathbb{V}(f)$$

We have seen in (7.62) that for an integral domain R the algebraic sets form the closed sets $\mathcal{Z}(R^I) = \{ \mathbb{V}(P) \mid P \subseteq A \}$ of the so-called *Zariski-topology* on R^I. Also the maps $\mathbb{I}$ and $\mathbb{V}$ thereby form a contra-variant Galois connection between the set of ideals of A and algebraic sets of R^I

$$\begin{array}{rcl} \{ \mathfrak{a} \mid \mathfrak{a} \trianglelefteq_{\mathrm{i}} A \} & \to & \left\{ X \mid X \subseteq R^I \right\} \\ \mathfrak{a} & \mapsto & \mathbb{V}(\mathfrak{a}) \\ \mathbb{I}(X) & \leftarrow\!\shortmid & X \end{array}$$

That is to say (1) for any $X \subseteq Y \subseteq R^I$ we get $\mathbb{I}(Y) \subseteq \mathbb{I}(X)$, (2) for any $\mathfrak{a}, \mathfrak{b} \trianglelefteq_{\mathrm{i}} A$ with $\mathfrak{a} \subseteq \mathfrak{b}$ we get $\mathbb{V}(\mathfrak{b}) \subseteq \mathbb{V}(\mathfrak{a})$, (3) for any $\mathfrak{a} \trianglelefteq_{\mathrm{i}} A$ we get $\mathfrak{a} \subseteq \mathbb{IV}(\mathfrak{a})$ and (4) for any $X \subseteq R^I$ we get $X \subseteq \mathbb{VI}(X)$. In this case we also have (5) $\mathbb{V}(P) = \mathbb{V}(\mathfrak{a})$ for any $P \subseteq A$, where we let $\mathfrak{a} := \langle P \rangle_{\mathrm{i}}$. As always with a Galois connection, we get $\mathbb{IVI} = \mathbb{I}$ and $\mathbb{VIV} = \mathbb{V}$ resulting in a one-to-one correspondence of the form

$$\begin{array}{rcl} \left\{ \mathbb{I}(X) \mid X \subseteq R^I \right\} & \longleftrightarrow & \{ \mathbb{V}(\mathfrak{a}) \mid \mathfrak{a} \trianglelefteq_{\mathrm{i}} A \} \\ \mathfrak{a} & \mapsto & \mathbb{V}(\mathfrak{a}) \\ \mathbb{I}(X) & \leftarrow\!\shortmid & X \end{array}$$

For a ring R with $\mathrm{NIL}(R) = 0$ the vanishing ideals $\mathbb{I}(X)$ are radical ideals, $\mathbb{I}(X) \in \mathrm{Srad}(A)$, but in general not every radical ideal occures as a vanishing ideal of some algebraic set $X \subseteq R^I$. It is not entirely satisfactory to not have a criterion for whether an ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} A$ is of the form $\mathfrak{a} = \mathbb{I}(X)$ for some $X \in \mathcal{Z}(R^I)$ and the Hilbert's Nullstellensatz is precisely the answer to this question: If R is an algebraically closed field satisfying $|I| < |R|$, then any radical ideal is the vanishing ideal of some $X \subseteq R^I$. If R is flawed, in one way or the other, there will be radical (even maximal) ideals not corresponding to an algebraic set. This will be the topic of corollary (8.62).

(8.58) Proposition: (viz. 599)
Let $(R, +, \cdot)$ be any non-zero, commutative ring, I be a non-empty index set and abbreviate the polynomial algebra $A := R[t_i \mid i \in I]$. Then we get the following statements

(i) If $\mathfrak{a} \trianglelefteq_{\mathrm{i}} A$ is a proper ideal (i.e. $\mathfrak{a} \neq A$) and φ is an R-algebra homomorphism φ of the following form, then for any $a \in R$ we get $\varphi(a1_A + \mathfrak{a}) = a$. In particular φ is non-zero and surjective:

$$\varphi : A \Big/ \mathfrak{a} \to R$$

(ii) Suppose that *for any* proper ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} A$ there is an R-algebra homomorphism φ of the following form, then R already has to be an algebraically closed field:

$$\varphi : A \Big/ \mathfrak{a} \to R$$

(iii) For any point $x = (x_i) \in R^I$ the ideal $\mathfrak{m}_x := \langle t_i - x_i \mid i \in I \rangle_{\mathfrak{i}}$ of A admits the one and only solution x and thereby $\mathfrak{m}_x$ is the kernel of the evaluation homomorphism $\varepsilon_x : A \to R : f \mapsto f(x)$:

$$\mathbb{V}(\mathfrak{m}_x) \;=\; \{\, x \,\} \quad \text{and} \quad \mathbb{I}(x) \;=\; \mathfrak{m}_x$$

(iv) If R is a reduced ring (that is $\text{NIL}(R) = 0$), then for any ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} A$ of A the radical ideal of $\mathfrak{a}$ is contained in the vanishing ideal of the algebraic set of $\mathfrak{a}$. Formally that is

$$\sqrt{\mathfrak{a}} \quad \subseteq \quad \mathbb{IV}(\mathfrak{a})$$

(8.59) Proposition: (viz. 601)
Similarly to the above, let $(F, +, \cdot)$ be a field, I be a non-empty index set and abbreviate the polynomial algebra $A := F[t_i \mid i \in I]$. Then we get the following statements

(i) If $x \in F^I$ is any point, then the ideal $\mathfrak{m}_x := \text{kn}(\varepsilon_x) = \langle t_i - x_i \mid i \in I \rangle_{\mathfrak{i}}$ is a maximal ideal of A and the following map is well-defined and injective

$$F^I \;\hookrightarrow\; \text{Smax}(A) \;:\; x \mapsto \mathfrak{m}_x$$

Definition: We say that A is **geometric**, iff this map even is surjective. That is iff every maximal ideal $\mathfrak{m} \in \text{Smax}(A)$ of A is of the form $\mathfrak{m} = \mathfrak{m}_x$ for some $x \in F^I$.

(ii) If A is geometric and $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} A$ is any proper ideal, then we obtain one-to-one correspondences between the algebraic set $\mathbb{V}(\mathfrak{a})$, the maximal ideals of $A/\mathfrak{a}$ and the algebra-homomorphisms from of $A/\mathfrak{a}$ to F, of the form

$$\begin{array}{ccccc} \mathbb{V}(\mathfrak{a}) & \longleftrightarrow & \text{Smax}\left(A \big/ \mathfrak{a}\right) & \longleftrightarrow & \text{ahom}\left(A \big/ \mathfrak{a}, F\right) \\ x & \mapsto & \mathfrak{m}_x \big/ \mathfrak{a} & \mapsto & \varepsilon_x : f + \mathfrak{a} \mapsto f(x) \\ & & \text{kn}(\varphi) & \mapsfrom & \varphi \end{array}$$

(iii) If I is finite and F is an algebraically closed field, then A is geometric.

(iv) If I is infinite, then A is geometric if and only if the polynomial ring $A[s]$ is geometric.

(8.60) Theorem: (viz. 604)
Let $(F, +, \cdot)$ be any non-zero, commutative ring, I be a non-empty index set and abbreviate the polynomial algebra $A := F[t_i \mid i \in I]$. Then the following nine statements (a) to (i) are equivalent

(a) F is an algebraically closed field and $|I| < |F|$.

(b) For any proper ideal $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} A$ there is an F-algebra homomorphism φ of the form

$$\varphi \;:\; A \big/ \mathfrak{a} \to F$$

(c) For any maximal ideal $\mathfrak{m} \trianglelefteq_{\mathfrak{i}} A$ there is an F-algebra homomorphism φ of the form

$$\varphi \;:\; A \big/ \mathfrak{m} \to F$$

(d) For any maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} A$ there is a point $x \in F^I$ such that $\mathfrak{m} = \mathfrak{m}_x$.

(e) The points of F^I correspond to the maximal ideals of A, under the following bijection

$$F^I \longleftrightarrow \mathrm{Smax}(A) \ : \ x \mapsto \mathfrak{m}_x$$

(f) For any maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} A$ and any finite subset $\Omega \subseteq I$ there is a tuple $a \in F^{\Omega}$ such that $\mathfrak{m} \cap F[t_i \mid i \in \Omega]$ is an ideal of the form

$$\mathfrak{m} \cap F[t_i \mid i \in \Omega] \ = \ \langle t_i - a_i \mid i \in \Omega \rangle_{\mathrm{i}} \ \trianglelefteq_{\mathrm{i}} \ F[t_i \mid i \in \Omega]$$

(g) F is a field and for any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} A$ we get $\mathbb{V}(\mathfrak{a}) = \emptyset$ if and only if $\mathfrak{a} = A$.

(h) F is a field and if $K : F$ is any field extension and $U = \{ u_i \mid i \in I \} \subseteq K$ is a subset, such that $F[U]$ is a field, then there is an isomorphism of F-algebras, of the form

$$F[U] \ \xrightarrow{\sim} \ F$$

(i) For any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} A$ the vanishing ideal of the algebraic set $\mathbb{V}(\mathfrak{a}) \subseteq F^I$ coincides with the radical ideal of $\mathfrak{a}$. Formally that is the identity

$$\sqrt{\mathfrak{a}} \ = \ \mathbb{IV}(\mathfrak{a})$$

Nota Item (f) might be a little misleading: In case $\Omega = \emptyset$ the assumption reads as: For any maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} A$ we get $\mathfrak{m} \cap F = 0$. But this property is equivalent to F being a field. Thus more explicitly we could reformulate (f) as: F is a field and for any maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} A$ and any *non-empty*, finite subset $\Omega \subseteq I$ we get the identity $\mathfrak{m} \cap F[t_i \mid i \in \Omega] = \langle t_i - a_i \mid i \in \Omega \rangle_{\mathrm{i}}$.

(8.61) Remark:
In 1952 S. Lang proved a similar equivalence: If F is an algebraically closed field and $P := \mathrm{PRF}(F)$ is the prime field of F, then property (d) holds true if and only if I is finite or $|I| < \mathrm{trdeg}(F : P)$. This is much the same as (a), since the transcendence degree satisfies

$$|F| \ = \ \max\{ \, |\mathbb{N}|, \mathrm{trdeg}(F : P) \, \}$$

(8.62) Corollary: (viz. 610)
If F is an algebraically closed field and I is a non-empty index set, such that $|I| < |F|$, then the algebraic subsets of F^I are in 1-to-1 correspondence with the radical ideals of the polynomial algebra $A := F[t_i \mid i \in I]$. That is, if we abbreviate

$$\begin{aligned} \mathrm{Srad}(A) \ &= \ \left\{ \mathfrak{a} \trianglelefteq_{\mathrm{i}} A \mid \sqrt{\mathfrak{a}} = \mathfrak{a} \right\} \\ \mathcal{Z}(F^I) \ &= \ \{ \, \mathbb{V}(\mathfrak{a}) \mid \mathfrak{a} \trianglelefteq_{\mathrm{i}} A \, \} \end{aligned}$$

then $\mathbb{V} : \mathrm{Srad}(A) \to \mathcal{Z}(F^I)$ and $\mathbb{I} : \mathcal{Z}(F^I) \to \mathrm{Srad}(A)$ are well-defined, mutually inverse maps: $\mathbb{I} = \mathbb{V}^{-1}$. If F is not algebraically closed or $|F| \leq |I|$, then $\mathbb{VI} = \mathbb{1}$ is still satisfied, but $\mathbb{IV} = \mathbb{1}$ (and

hence the correspondence) fails.

(8.63) Corollary: (viz. 610)
Let R be any commutative ring and $I \subseteq J$ be index sets, such that I is non-empty. Then we abbreviate the polynomial rings $R[I] := R[t_i \mid i \in I]$ and likewise $R[J] := R[t_j \mid j \in J]$. Let us denote the canonical projection from R^J onto R^I by π_I^J below, then we get

$$\pi_I^J \;:\; R^J \;\twoheadrightarrow\; R^I \;:\; (x_j)_{j\in J} \;\mapsto\; (x_i)_{i\in I}$$

(i) Let $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R[I]$ be an ideal in the polynomial sub-ring $R[I] \leq R[J]$, then the set of the pushed-out ideal $\mathfrak{a}R[J]$ is just the pull-back of the algebraic set of $\mathfrak{a}$, that is

$$\mathbb{V}\big(\mathfrak{a}\,R[J]\big) \;\;=\;\; \big(\pi_I^J\big)^{-1}\big(\mathbb{V}(\mathfrak{a})\big)$$

(ii) If R is an infinite integral domain and $X \subseteq R^I$ is an algebraic set, then the vanishing ideal of the pull-back of X is just the pushed-out vanishing ideal of X, that is

$$\mathbb{I}\Big(\big(\pi_I^J\big)^{-1}(X)\Big) \;\;=\;\; \mathbb{I}(X)\,R[J]$$

(iii) In particular: If R is an algebraically closed field with $|I| < |R|$ and $\mathfrak{u} \trianglelefteq_{\mathfrak{i}} R[J]$ is an ideal of the form $\mathfrak{u} = \mathfrak{a}\,R[J]$ for some $\mathfrak{a} \trianglelefteq_{\mathfrak{i}} R[I]$, then we get

$$\mathbb{I}\,\mathbb{V}(\mathfrak{u}) \;\;=\;\; \sqrt{\mathfrak{u}}$$

Proof of (8.58):

(i) The unit element of $A/\mathfrak{a}$ is $1_A + \mathfrak{a}$, the R-algebra homomorphism is required to map $\varphi(1_A + \mathfrak{a}) = 1_R$. Thus for any $a \in R$ we get $\varphi(a1_A + \mathfrak{a}) = a\varphi(1_A + \mathfrak{a}) = a1_R = a$, as $a1_A + \mathfrak{a} = a(1_A + \mathfrak{a})$ and φ is R-linear. In particular $\mathrm{im}(\varphi) = R$. Suppose $\varphi = 0$, then we had $\varphi(1_A + \mathfrak{a}) = 0_R$ which would mean $0_R = 1_R$, in contradiction to $R \neq 0$.

(ii) In a first step, let us prove, that R is a field: So consider any $a \in R$ with $a \notin R^*$, we need to prove $a = 0$. To see this define the ideals $\mathfrak{h} := \langle t_i \mid i \in I\rangle$ and $\mathfrak{a} := \mathfrak{h} + aA$. That is $\mathfrak{a}$ is generated by $a1_A \in A$ and all the variables $t_i \in A$. Now regard the homomorphism

$$A \;\twoheadrightarrow\; R\Big/_{aR} \;:\; f \;\mapsto\; f[0] + aR$$

Clearly $\mathfrak{a}$ is contained in the kernel of this homomorphism. Conversely, if $f[0] + aR = 0 + aR$, then $f[0] = ab$ for some $b \in R$. Hence $f - ab \in \mathfrak{h}$ and from this we get $f \in \mathfrak{h} + ab \subseteq \mathfrak{a}$. Thus $\mathfrak{a}$ is the kernel of the above homomorphism and therefore $A/\mathfrak{a}$ and R/aR are isomorphic as R-algebras. If we had $\mathfrak{a} = A$ then R/aR would have to be zero, such that $aR = R$ in contradiction, to $a \notin R^*$. We conclude that $\mathfrak{a}$ is a proper ideal. Hence, by assumption there is a homomorphism φ of the form $\varphi : A/\mathfrak{a} \to R$ and by (i) we know that this is surjective

$$R\Big/_{aR} \;\xrightarrow{\sim}\; A\Big/_{\mathfrak{a}} \;\twoheadrightarrow\; R$$

In particular $R/aR \twoheadrightarrow R : b + aR \mapsto b1_A + \mathfrak{a} \mapsto \varphi(b1_A + \mathfrak{a}) = b$ is surjective. But as $a + aR \mapsto a$ and $a + aR = 0 + aR \mapsto 0$ the well-definedness of this map yields $a = 0$.

(ii) We have just proved, that R is a field, it remains to show, that R even is algebraically closed: To do this fix any $j \in I$, let $H := I \setminus \{j\}$ and consider an arbitrary, non-constant polynomial $f \in R[t_j] \subseteq A$ over R. Now define the ideals $\mathfrak{h} := \langle t_i \mid i \in H \rangle$ and $\mathfrak{a} := fA + \mathfrak{h}$. That is $\mathfrak{a}$ is generated by f and all the t_i with $i \neq j$. Then it is clear, that $R[t_j] \xrightarrow{\sim} A/\mathfrak{h} : g \mapsto g + \mathfrak{h}$ is an isomorphism of R-algebras, that maps $fR[t_j]$ to $\mathfrak{a}/\mathfrak{h}$. And therefore we find an isomorphism of the form

$$R[t_j] \Big/ fR[t_j] \xrightarrow{\sim} A/\mathfrak{h} \Big/ \mathfrak{a}/\mathfrak{h} \xrightarrow{\sim} A \Big/ \mathfrak{a} : g + fR[t_j] \mapsto g + \mathfrak{a}$$

Now $R[t_j]/fR[t_j]$ is a $\deg(f)$-dimensional R-vector space and as f is non-constant, we have $\deg(f) \geq 1$. In particular $R[t_j]/fR[t_j] \neq 0$ and therefore $A/\mathfrak{a} \neq 0$. That is $\mathfrak{a}$ is a proper ideal and by assumption there is a homomorphism φ of R-algebras such that we can build up the chain

$$\varphi : R[t_j] \Big/ fR[t_j] \xrightarrow{\sim} A \Big/ \mathfrak{a} \twoheadrightarrow R$$

Abbreviate the ideal $\mathfrak{f} := fR[t_j]$ and let $x := \varphi(t_j + \mathfrak{f}) \in R$. As φ is a homomorphism of R-algebras, it commutes with polynomials and hence we can compute

$$f(x) = f\big(\varphi(t_j + \mathfrak{f})\big) = \varphi\big(f(t_j + \mathfrak{f})\big) = \varphi\big(f(t_j) + \mathfrak{f}\big) = \varphi(f + \mathfrak{f}) = 0_R$$

as $f \in \mathfrak{f}$. Thus we have found a root $x \in R$ of f. As f was an arbitrary non-constant polynomial, this means *any* non-constant polynomial over R has a root, which means R is algebraically closed.

(iii) Let us first verify $\mathbb{V}(\mathfrak{m}_x) = \{x\}$: If $y \in \mathbb{V}(\mathfrak{m}_x)$, then for any $i \in I$ we can compute $0 = (t_i - x_i)(y_i) = y_i - x_i$ and hence $y_i = x_i$. That is $y = x$, so we have the inclusion from left to right. Conversely if $f \in \mathfrak{m}_x$, then there is a finite subset $\Omega \subseteq I$ such that

$$f(t) = \sum_{i \in \Omega} f_i(t) \cdot (t_i - x_i)$$

for some $f_i \in A$. But then we get $f(x) = \sum_i f_i(x)(x_i - x_i) = 0$ and as this is true for any $f \in \mathfrak{m}_x$ we found $x \in \mathbb{V}(\mathfrak{m}_x)$, which is the inclusion from right to left.

(iii) To continue we need a short preparation: For any $x = (x_i) \in R^I$ let us define the R-algebra homomorphism α_x by algebraic expansion of $t_i \mapsto t_i - x_i$ that is

$$\alpha_x : A \to A : f(t) \mapsto f(t - x)$$

These homomorphisms clearly satisfy $\alpha_x \alpha_{-x} = \mathbb{1}_A$ and $\alpha_{-x} \alpha_x = \mathbb{1}_A$ such that they are automorphisms. And by construction it also is clear, that

$$\alpha_x(\mathfrak{m}_0) = \mathfrak{m}_x$$

Let us first consider $x = 0$, then for any $f \in A$ we get $\varepsilon_0(f) = f(0) = f[0]$ such that $\varepsilon_0(f) = 0$ is

equivalent to $f \in \mathfrak{m}_0$. That is we have

$$\mathsf{kn}\big(\varepsilon_0\big) \;=\; \mathfrak{m}_0$$

Now for any $f \in A$ and any $x \in R^I$ compute $\varepsilon_x \alpha_x(f) = \alpha_x(f)(x) = f(x-x) = f(0)$. That is $\alpha_x(f) \in \mathsf{kn}(\varepsilon_x)$ is equivalent to $f(0) = 0$ which in turn is equivalent to $f \in \mathfrak{m}_0$. If we apply α_x to $f \in \mathfrak{m}_0 = \alpha_{-x}(\mathfrak{m}_x)$ we see that $f \in \mathfrak{m}_0$ equivalent to $\alpha_x(f) \in \mathfrak{m}_x$. Thus for $g := \alpha_x(f)$ we have $g \in \mathsf{kn}(\varepsilon_x)$ if and only if $g \in \mathfrak{m}_x$. And as α_x is surjective (even bijective) this is

$$\mathsf{kn}\big(\varepsilon_x\big) \;=\; \mathfrak{m}_x$$

Let us take a look at $\mathbb{I}(x) = \{\, f \in A \mid f(x) = 0 \,\}$. We see, that this is precisely the definition of $\mathsf{kn}(\varepsilon_x)$, such that the above identity can be extended, to

$$\mathbb{I}(x) \;=\; \mathsf{kn}\big(\varepsilon_x\big) \;=\; \mathfrak{m}_x$$

(iv) Consider any $g \in \sqrt{\mathfrak{a}}$, that is $g^n \in \mathfrak{a}$ for some $n \in \mathbb{N}$, then we need to show $g \in \mathbb{IV}(\mathfrak{a})$. More explicitly we need to verify $g(x) = 0$ for any $x \in \mathbb{V}(\mathfrak{a})$. As $x \in \mathbb{V}(\mathfrak{a})$ we have $f(x) = 0$ for any $f \in \mathfrak{a}$, in particular $g^n(x) = 0$. But this is $g(x)^n = 0$ and as R is reduced this implies $g(x) = 0$. As this is true for any $x \in \mathbb{V}(\mathfrak{a})$, we are done.

□

Proof of (8.59):

(i) Let us first prove, that any ideal of the form $\mathfrak{m}_x$ is maximal: For $x = 0 \in F^I$ we have $\mathfrak{m}_0 = \langle t_i \mid i \in I \rangle$ and thereby a canonical isomorphism of the form

$$F \;\xrightarrow{\sim}\; A\Big/_{\mathfrak{m}_0} \,:\, a \mapsto a1_A + \mathfrak{m}_0$$

And as F is a field, this means $A/\mathfrak{m}_0$ is, as well, such that $\mathfrak{m}_0$ is a maximal ideal of A. But as $\mathfrak{m}_x = \alpha_x(\mathfrak{m}_0)$ and α_x is an automorphism of A by (refer to the proof of 8.58.(iii)) and $\mathfrak{m}_0$ is a maximal ideal, so are all the ideals $\mathfrak{m}_x$.

The injectivity of the map $x \mapsto \mathfrak{m}_x$ is easy to see: Consider any two points $x = (x_i)$ and $y = (y_i) \in F^I$ such that $\mathfrak{m}_x = \mathfrak{m}_y$. Then for any $i \in I$ we have $t_i - x_i \in \mathfrak{m}_y$. In particular $x_i - y_i = (t_i - y_i) - (t_i - x_i) \in \mathfrak{m}_y$. If we had $x_i \neq y_i$ then $x_i - y_i \in F^* = A^*$ is a unit and hence $\mathfrak{m}_y = A$ in contradiction to the maximality of $\mathfrak{m}_y$. Thus we have $x_i = y_i$ for any $i \in I$ and hence $x = y$.

(ii) Let us first prove the correspondence for the maximal spectrum of $A/\mathfrak{a}$: If $\overline{\mathfrak{m}} \trianglelefteq_{\mathrm{i}} A/\mathfrak{a}$ is a maximal ideal, then by the correspondence theorem of ideals it is of the form $\overline{\mathfrak{m}} = \mathfrak{m}/\mathfrak{a}$ for some $\mathfrak{m} \in \mathsf{Smax}(A)$ with $\mathfrak{a} \subseteq \mathfrak{m}$. By assumption this means $\mathfrak{m} = \mathfrak{m}_x$ for some $x \in F^I$. As $\mathfrak{a} \subseteq \mathfrak{m} = \mathfrak{m}_x$ we get $\mathbb{V}(\mathfrak{m}_x) \subseteq \mathbb{V}(\mathfrak{a})$, but $\mathbb{V}(\mathfrak{m}_x) = \{\, x \,\}$ is clear, such that we have $x \in \mathbb{V}(\mathfrak{a})$. Altogether we have

$$\mathsf{Smax}\left(A\Big/_{\mathfrak{a}}\right) \;\subseteq\; \left\{ \mathfrak{m}_x\Big/_{\mathfrak{a}} \;\middle|\; x \in \mathbb{V}(\mathfrak{a}) \right\}$$

Conversely consider any $x \in \mathbb{V}(\mathfrak{a})$, then $\mathfrak{m}_x \trianglelefteq_{\mathrm{i}} A$ is maximal by (i). Applying $\mathbb{I}$ we get $\mathfrak{a} \subseteq \mathbb{IV}(\mathfrak{a}) \subseteq \mathbb{I}(x)$. But $\mathbb{I}(x) = \mathsf{kn}(\varepsilon_x) = \mathfrak{m}_x$ by (8.58.(iii)) such that we have $\mathfrak{a} \subseteq \mathfrak{m}_x$ and hence

$\mathfrak{m}_x/\mathfrak{a} \trianglelefteq_{\mathrm{i}} A/\mathfrak{a}$ is maximal, by the correspondence theorem of ideals.

That is the map $x \mapsto \mathfrak{m}_x/\mathfrak{a}$ is well-defined and surjective. It remains to prove its injectivity: If $\mathfrak{m}_x/\mathfrak{a} = \mathfrak{m}_x/\mathfrak{a}$, then $\mathfrak{m}_x = \mathfrak{m}_y$ because of the correspondence of ideals, but from this we already get $x = y$, according to (i).

(ii) Now for the second part: The correspondence of the maximal spectrum and the homomorphisms of F-algebras: If we start with a maximal ideal $\mathfrak{m}_x/\mathfrak{a}$ (that is $x \in \mathbb{V}(\mathfrak{a})$), then we have to show that ε_x is well defined. So consider any two $f, g \in A$ with $f + \mathfrak{a} = g + \mathfrak{a}$. That is $d := f - g \in \mathfrak{a} \subseteq \mathbb{IV}(\mathfrak{a})$. As $x \in \mathbb{V}(\mathfrak{a})$ and $d \in \mathbb{IV}(\mathfrak{a})$ we have $d(x) = 0$, which is $f(x) = g(x)$. Thus ε_x is well-defined.

If we start with $\varphi : A/\mathfrak{a} \to F$, then φ is surjective by (i) and hence $(A/\mathfrak{a})/\mathrm{kn}(\varphi)$ is isomorphic to F, which is a field and hence $\mathrm{kn}(\varphi) \trianglelefteq_{\mathrm{i}} A/\mathfrak{a}$ is a maximal ideal. Thus the converse map is well-defined, too. It remains to prove, that they are mutally inverse:

If we start with a maximal ideal $\overline{\mathfrak{m}} = \mathfrak{m}_x/\mathfrak{a}$ of $A/\mathfrak{a}$ we have to verify that $\mathrm{kn}(\varepsilon_x)$ is $\mathfrak{m}_x/\mathfrak{a}$ again: But as we have seen in (8.58.(iii)) $\mathrm{kn}(\varepsilon_x) = \{ f + \mathfrak{a} \mid f(x) = 0 \} = \mathfrak{m}_x/\mathfrak{a}$ is satisfied. Conversely, if we start with a homomorphism φ, then $\mathrm{kn}(\varphi) = \mathfrak{m}_x/\mathfrak{a}$ for some $x \in \mathbb{V}(\mathfrak{a})$. So we have to verify $\varphi = \varepsilon_x$: That is we consider any $f \in A$ and have to show $\varphi(f + \mathfrak{a}) = \varepsilon_x(f + \mathfrak{a}) = f(x)$.

Let $a := \varphi(f + \mathfrak{a})$, then by (8.58.(i)) we have $\varphi(a1_A + \mathfrak{a}) = a = \varphi(f + \mathfrak{a})$ and therefore $(f - a1_A) + \mathfrak{a} \in \mathrm{kn}(\varphi) = \mathfrak{m}_x/\mathfrak{a}$. Thus we found $f - a1_A \in \mathfrak{m}_x$, which is nothing but $f(x) = a1_A(x) = a$. Therefore $\varepsilon_x(f + \mathfrak{a}) = f(x) = a = \varphi(f + \mathfrak{a})$ such that $\varphi = \varepsilon_x$.

- Nota Item (iii) is the classical Hilbert's Nullstellensatz. As this is a most famous result, we will give 2 alternative proofs: The first is due to O. Zariski who saw an application of Noetherian normalization here. The second is an application of Jacobson rings and it's merit is due to several mathematicians, primarily W. Krull, and O. Goldman.

(iii) *Zariski's Proof:* As I is non-empty and finite, we may assume $I = \{ 1, \ldots, n \}$ for some $1 \leq n \in \mathbb{N}$. Consider any maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} A$ and let $L := A/\mathfrak{m}$. Then L is a finitely generated F-algebra, as $L = F[t_1 + \mathfrak{m}, \ldots, t_n + \mathfrak{m}]$. By the Noetherian normalization theorem, there is an algebraically independent set $\{ z_1, \ldots, z_r \} \subseteq L$ such that for $K := F[z_1, \ldots, z_r]$ the extension $L : K$ is finite (we also know $r \leq n$, but this is irrelevant here). In particular $L : K$ is an integral extension of rings.

As $\mathfrak{m}$ is a maximal ideal L is a field and as $K \subseteq L$, L also is torsion-free, as a K-module. As $L : K$ is integral, this implies K to be a field, too. Suppose $r \geq 1$, then $z_1^{-1} \in K$, that is $z_1 f(z_1, \ldots, z_r) = 1_L$ for some $f \in F[t_1, \ldots, t_r]$. But then $0 = \deg_1(1_L) = 1 + \deg_1(f)$, which is absurd. Hence we find $r = 0$, that is $K = F1_L$. That is $L : F$ is finite, say $m := [L : F]$. Hence any $x \in L$ satisfies an equation $g \in F[t]$ of degree $\deg(g) \leq m + 1$. But F was assumed to be algebraically closed hence $g(x) = 0$ implies $x \in F\,1_L$ and therefore

$$\alpha : F \xrightarrow{\sim} L : a \mapsto a1_L$$

is surjective. And as F is a field and $\alpha \neq 0$ it also is injective. Pick up $x_i \in F$ such that $x_i + \mathfrak{m} = x_i 1_L = t_i + \mathfrak{m} \in A/\mathfrak{m} = L$. Then for any $i \in 1 \ldots n$ we get $t_i - x_i \in \mathfrak{m}$ and hence $\mathfrak{m}_x \subseteq \mathfrak{m}$. As F is a field, $\mathfrak{m}_x$ is maximal and $\mathfrak{m} \neq A$ such that $\mathfrak{m}_x = \mathfrak{m}$.

(iii) *Goldman-Like Proof:* As I is non-empty and finite, we may assume $I = 1 \dots n$ for some $1 \leq n \in \mathbb{N}$. Then we use induction on n, starting with $n = 1$, that is $A = F[s]$ for $s := t_1$. Consider any maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} F[s]$, then $\mathfrak{m} = gF[s]$ for some $g \in F[s]$. As $\mathfrak{m} \neq F[s]$ we have $g \notin F[s]^* = F^*$, that is g is non-constant. As F is algebraically closed, this means $g(x) = 0$ for some $x \in F$ and thereby $s - x \mid g$. By maximality of $\mathfrak{m} = gF[s] \subseteq \langle s - x \rangle = \mathfrak{m}_x$ we have $\mathfrak{m} = \mathfrak{m}_x$ which means that $F[s]$ is geometric.

Now for the induction step: We already know that $A = F[t_1, \dots, t_n]$ is geometric and have to prove that $F[t_1, \dots, t_n, t_{n+1}] = A[s]$ for $s := t_{n+1}$ is geometric, too. Thus we consider any maximal ideal $\mathfrak{n} \trianglelefteq_{\mathrm{i}} A[s]$. As F is a field, it also is a Jacobson ring and hence A and $A[s]$ are Jacobson rings, too, according to (2.170.(iv)). One of the equivalent properties of A being jacobson is that $\mathfrak{m} := \mathfrak{n} \cap A$ is a maximal ideal again, as we have seen in (2.171.(iii)). By induction hypothesis there then is some $x \in F^n$ such that $\mathfrak{m} = \mathfrak{m}_x$. Now consider the epimorphism

$$\varepsilon_x \ : \ A[s] \ \twoheadrightarrow \ F[s] \ : \ g(t)(s) \mapsto g(x)(s)$$

Consider $g \in A[s]$ in the form $g(t)(s) = \sum_k g_k(t)s^k$ for some $g_k \in A$. Then we get $\varepsilon_x(g) = g(x)(s) = \sum_k g_k(x)s^k = 0$ if and only $g_k(x) = 0$ for any $k \in \mathbb{N}$. This again is $g_k \in \mathfrak{m}_x$ (for any $k \in \mathbb{N}$) and thereby we get

$$\mathsf{kn}\big(\varepsilon_x\big) \ = \ \mathfrak{m}_x[s]$$

As ε_x is surjective we find that this induces an isomorphism of F-algebras, of the form

$$\bar{\varepsilon}_x \ : \ A[s] \Big/ \mathfrak{m}_x[s] \ \xrightarrow{\sim} \ F[s] \ : \ g(t)(s) + \mathfrak{m}_x[s] \mapsto g(x)(s)$$

As $\mathfrak{n}$ is maximal and $\mathfrak{m}_x[s] = (\mathfrak{n} \cap A)[s] \subseteq \mathfrak{n}$ we find that $\mathfrak{n}/\mathfrak{m}_x$ is a maximal ideal of $A/\mathfrak{m}_x[s]$. This is transferred to $F[s]$ under $\bar{\varepsilon}_x$, that is we have

$$\bar{\varepsilon}_x \left(\mathfrak{n} \Big/ \mathfrak{m}_x[s] \right) \ \in \ \mathsf{Smax}\big(F[s]\big)$$

By the case $n = 1$ this means that this ideal is of the form $(s - y)F[s]$ for some $y \in F$. In other words $t_{n+1} - y + \mathfrak{m}_x[s] \in \mathfrak{n}/\mathfrak{m}_x[s]$, which is $t_{n+1} - y \in \mathfrak{n}$. But as for any $k \in 1 \dots n$ we also have $t_k - x_k \in \mathfrak{m}_x = \mathfrak{n} \cap A$ we find $\mathfrak{m}_{(x,y)} \subseteq \mathfrak{n}$. And by the maximality of $\mathfrak{m}_{(x,y)}$ this implies $\mathfrak{m}_{(x,y)} = \mathfrak{n}$, that is $A[s]$ is geometric again.

(iv) Let us now consider an infinite set I, that is there is a subset $\Omega := \{\, i(n) \mid n \in \mathbb{N} \,\} \subseteq I$. Then we can use this subset to shift the variables t_i of A according to $t_{i(n)} \mapsto t_{i(n-1)}$ for $1 \leq n \in \mathbb{N}$ and $t_i \mapsto t_i$ for $i \notin \Omega$. Then we freed up $t_{i(0)} \mapsto s$ and thereby gain an isomorphism of F-algebras, by extension of

$$\Phi \ : \ A \ \xrightarrow{\sim} \ A[s] \ : \ t_i \mapsto \begin{cases} s \text{ if } i = i(0) \\ t_{i(n)} \text{ if } i = i(n+1) \\ t_i \text{ if } i \notin \Omega \end{cases}$$

If now $x = (x_i) \in F^I$, then we need to shift $x \mapsto x' := (x'_i)$ where $x'_{i(n)} := x_{i(n+1)}$ for $n \in \mathbb{N}$,

$x'_i := x_i$ for $i \notin \Omega$ and $y := x_{i(0)}$. Then it is clear that this isomorphism links the maximal ideals

$$\Phi(\mathfrak{m}_x) \;=\; \mathfrak{m}_{(x',y)}$$

Thus, if A is geometric and $\mathfrak{n} \trianglelefteq_{\mathrm{i}} A[s]$ is a maximal ideal, then $\Phi^{-1}(\mathfrak{m}) \trianglelefteq_{\mathrm{i}} A$ is a maximal ideal, as well. Hence we find an $x \in F^I$ such that $\Phi(\mathfrak{n}) = \mathfrak{m}_x$ and therefore $\mathfrak{n} = \Phi(\mathfrak{m}_x) = \mathfrak{m}_{(x',y)} \trianglelefteq_{\mathrm{i}} A[s]$. As we can do this for any maximal ideal $\mathfrak{n}$ of $A[s]$ we see that $A[s]$ is geometric again. The converse direction is just the same thing, using the transfer of $\mathfrak{m} \trianglelefteq_{\mathrm{i}} A$ to $A[s]$ under Φ^{-1}.

□

Proof of (8.60):
We will first prove the equivalence of the statements (b) to (h) in pairs. Note that due to (8.58.(ii)) property (b) implies that F is an algebraically closed field. Thus whenever we have (b) on our side, we may assume F to be a field (an even algebraically closed one).

- The implication (b) $\implies$ (c) is trivial, we have to commit ourselves to (c) $\implies$ (b) only: For this we simply choose a maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} A$, such that $\mathfrak{a} \subseteq \mathfrak{m}$. Then we obtain a well-defined homomorphism
$$\varrho \;:\; {}^{A}\!\Big/_{\mathfrak{a}} \twoheadrightarrow {}^{A}\!\Big/_{\mathfrak{m}} \;:\; f + \mathfrak{a} \mapsto f + \mathfrak{m}$$
and by assumption (c) there also is a homomorphism $\varphi : A/\mathfrak{m} \to F$. Thus by composition $\varphi\varrho$ we get the desired homomorphism from $A/\mathfrak{a}$ to F.

- The next step will be (d) $\implies$ (c): Consider any maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} A$, then we have to find a homomorphism φ of R-algebras, of the form $\varphi : A/\mathfrak{m} \to F$. By assumption (d) there is some $x \in F^I$ such that $\mathfrak{m} = \mathfrak{m}_x$, thus the candidate is $\varepsilon_x : A \to F : f \mapsto f(x)$. By (8.58.(iii)) we have $\mathrm{kn}(\varepsilon_x) = \mathfrak{m}_x = \mathfrak{m}$ and thereby ε_x induces φ via
$$\varphi \;:\; {}^{A}\!\Big/_{\mathfrak{m}} \to F \;:\; f + \mathfrak{m} \mapsto f(x)$$
For the converse direction (c) $\implies$ (d) we are given any maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} A$ and have to find some $x \in F^I$ such that $\mathfrak{m} = \mathfrak{m}_x$. With (c) comes (b) and hence F is a field here. And by assumption (c) there is a homomorphism φ of the form $\varphi : A/\mathfrak{m} \to F$. By (8.58.(i)) φ is surjective and $\varphi \neq 0$. Now consider $\mathrm{kn}(\varphi) \trianglelefteq_{\mathrm{i}} A/\mathfrak{m}$. As $\mathfrak{m}$ is maximal, $A/\mathfrak{m}$ is a field, such that either $\mathrm{kn}(\varphi) = 0$ or $\mathrm{kn}(\varphi) = A/\mathfrak{m}$. The latter is ruled out, by $\varphi \neq 0$ and hence φ also is injective. Altogether we have an isomorphism
$$\varphi \;:\; {}^{A}\!\Big/_{\mathfrak{m}} \xrightarrow{\sim} F$$
of F-algebras. For any $i \in I$ let $x_i := \varphi(t_i + \mathfrak{m}) \in F$ and $x := (x_i)$, then we have $\varphi(t_i - x_i 1_A + \mathfrak{m}) = \varphi(t_i + \mathfrak{m}) - x_i\varphi(1_A + \mathfrak{m}) = x_i - x_i = 0$. Thus $t_i - x_i 1_A + \mathfrak{m} \in \mathrm{kn}(\varphi) = 0$ such that $t_i - x_i 1_A \in \mathfrak{m}$. As this is true for any $i \in I$ we get $\mathfrak{m}_x \subseteq \mathfrak{m}$. But as F is a field, $\mathfrak{m}_x$ is a maximal ideal, by (8.58.(v)) and as $\mathfrak{m} \neq A$ this implies $\mathfrak{m}_x = \mathfrak{m}$.

- The implication (e) $\implies$ (d) is trivial again, it is the surjectivity of the correspondence in (e). For the converse direction (d) $\implies$ (e), we also got (b) from (d) and hence F is a field. Therefore (8.59.(i)) already tells us, that the map $x \mapsto \mathfrak{m}_x$ is well-defined and injective. And if $\mathfrak{m} \trianglelefteq_{\mathrm{i}} A$ is

any maximal ideal, then by assumption (d) there is some $x \in F^I$ such that $\mathfrak{m} = \mathfrak{m}_x$. This also is the surjectivity of $x \mapsto \mathfrak{m}_x$ and hence the correspondence.

- Property (f) is just a reformulation of (d), of finite kind. Let us deal with the case $\Omega = \emptyset$ first: In this case $F[t_i \mid i \in \Omega] = F$ and $\langle t_i - a_i \mid i \in \Omega \rangle = \langle \emptyset \rangle = 0$. Thus (f) reads as $\mathfrak{m} \cap F = 0$ for any $\mathfrak{m} \in \operatorname{Smax}(A)$. If F is a field, then $\mathfrak{m} \cap F = 0$ is clear, as 0 is the only proper ideal of F and $\mathfrak{m} \cap F$ even is a prime ideal of F. Conversely, we assume $A \cap \mathfrak{m} = 0$ for any $\mathfrak{m} \in \operatorname{Smax}(A)$ and need to show that F is a field: Consider any $a \in F \setminus F^*$. Then $aF \trianglelefteq_{\mathfrak{i}} F$ is a proper ideal and hence there is a maximal ideal $\mathfrak{m}_0 \in \operatorname{Smax}(F)$ containing $aF \subseteq \mathfrak{m}_0$. Then $\mathfrak{m} := \{ f \in A \mid f(0) \in \mathfrak{m}_0 \}$ is a maximal ideal of A. Yet $a \in \mathfrak{m}_0 = \mathfrak{m} \cap F = 0$ implies $a = 0$ and as a has been arbitrary we conclude $F \setminus \{0\} = F^*$, which means F is a field.

 We start by proving (d) $\implies$ (f): With (d) comes (b) and hence we find that F is a field. Now, if $\Omega \subseteq I$ is a non-empty finite set and $\mathfrak{m} \trianglelefteq_{\mathfrak{i}} A$ is a maximal ideal, then by assumption (d) we have $\mathfrak{m} = \mathfrak{m}_x$. That is for any $i \in I$ there is some $x_i \in F$, such that $t_i - x_i \in \mathfrak{m}_x = \mathfrak{m}$. For $i \in \Omega$ we also have $t_i - x_i \in A_0 := F[t_i \mid i \in \Omega]$ and therefore

 $$\langle t_i - x_i \mid i \in \Omega \rangle \quad \subseteq \quad \mathfrak{m} \cap A_0$$

 As F is a field $\langle t_i - x_i \mid i \in \Omega \rangle$ is a maximal ideal of A_0, according to (8.59.(i)). Yet $\mathfrak{m} \cap A_0$ is a proper ideal (even a prime ideal) and therefore this inclusion turns into an identity again.

 Conversely for (f) $\implies$ (d) we find that F is a field, by taking $\Omega = \emptyset$. We now start with a maximal ideal $\mathfrak{m}$ and have to find some $x \in F^I$, such that $\mathfrak{m} = \mathfrak{m}_x$. To do this pick up an arbitrary $i \in I$. Then $\Omega := \{i\} \subseteq I$ is a finite set and hence by assumption (f) we have $\mathfrak{m} \cap F[t_i] = \langle t_i - x_i \rangle$ for some $x_i \in F$. As we can do this with any $i \in I$ we find a point $x = (x_i) \in F^I$ with $t_i - x_i \in \mathfrak{m}$ for any $i \in I$. That is $\mathfrak{m}_x \subseteq \mathfrak{m}$. As F is a field $\mathfrak{m}_x$ is a maximal ideal of A, by (8.59.(i)) again. And as $\mathfrak{m}$ is proper (even maximal) the inclusion $\mathfrak{m}_x \subseteq \mathfrak{m}$ turns into the identity desired $\mathfrak{m}_x = \mathfrak{m}$.

- The step (d) $\implies$ (g) is easy again: With (d) we also have (b) and hence F is a field. And if $\mathfrak{a} = A$, then $1_A \in \mathfrak{a}$ and hence $\mathbb{V}(\mathfrak{a}) \subseteq \mathbb{V}(1_A) = \emptyset$. Conversely, if $\mathfrak{a} \neq A$, then there is a maximal ideal $\mathfrak{m} \trianglelefteq_{\mathfrak{i}} A$ such that $\mathfrak{a} \subseteq \mathfrak{m}$. And by assumption (d) we have $\mathfrak{m} = \mathfrak{m}_x$ for some $x \in F^I$. Thereby $\{ x \} = \mathbb{V}(\mathfrak{m}_x) = \mathbb{V}(\mathfrak{m}) \subseteq \mathbb{V}(\mathfrak{a})$ and in particular $\mathbb{V}(\mathfrak{a}) \neq \emptyset$ is non-empty.

 Conversely for (g) $\implies$ (d) we are given some maximal ideal $\mathfrak{m} \trianglelefteq_{\mathfrak{i}} A$. As $\mathfrak{m} \neq A$ we have $\mathbb{V}(\mathfrak{m}) \neq \emptyset$ by assumption (g). Thus there is some $x \in F^I$ with $x \in \mathbb{V}(\mathfrak{m})$. That is for any $f \in \mathfrak{m}$ we have $f(x) = 0$, which can be put as $f \in \operatorname{kn}(\varepsilon_x)$. In other words we find the inclusion $\mathfrak{m} \subseteq \operatorname{kn}(\varepsilon_x) = \mathfrak{m}_x$ by (8.58.(iii)). But from this, as $\mathfrak{m}$ is maximal and $\mathfrak{m}_x \neq A$, we conclude $\mathfrak{m} = \mathfrak{m}_x$.

- Let us get to the bottom of this (g) $\implies$ (h): With (g) we have (b) and hence know, that F is a field (even algebraically closed). Now define the evaluation homomorphism

 $$\varepsilon \; : \; A \; \twoheadrightarrow \; F[U] \; : \; t_i \mapsto u_i$$

 As this is surjective, we have $A/\operatorname{kn}(\varepsilon) \xrightarrow{\sim} F[U]$ under $f + \operatorname{kn}(\varepsilon) \mapsto \varepsilon(f) = f(u)$. As $F[U]$ is assumed to be a field, $\operatorname{kn}(\varepsilon)$ is a maximal ideal of A. Thus by assumption there is some $x \in F^I$

with $x \in \mathbb{V}(\ker(\varepsilon))$. Then we find

$$\ker(\varepsilon) \quad \subseteq \quad \mathbb{IV}\big(\ker(\varepsilon)\big) \quad \subseteq \quad \mathbb{I}(x) \quad = \quad \mathfrak{m}_x$$

But $\ker(\varepsilon)$ is maximal and $\mathfrak{m}_x$ is proper, such that we have $\ker(\varepsilon) = \mathfrak{m}_x$. Now consider the following isomorphisms, as these can be composed to yield the desired isomorphism

$$\begin{array}{ccccccc} F[U] & \xrightarrow{\sim} & A\big/_{\ker(\varepsilon)} & = & A\big/_{\mathfrak{m}_x} & \xrightarrow{\sim} & F \\ \varepsilon(f) & \mapsto & f + \ker(\varepsilon) & = & f + \mathfrak{m}_x & \mapsto & f(x) \end{array}$$

Let us proceed with (h) $\implies$ (g): If $\mathfrak{a} = A$, then $1_A \in \mathfrak{a}$ and hence $\mathbb{V}(\mathfrak{a}) \subseteq \mathbb{V}(1_A) = \emptyset$. Conversely consider a proper ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} A$, then there is a maximal ideal $\mathfrak{m} \in \operatorname{Smax}(A)$ containing $\mathfrak{a} \subseteq \mathfrak{m}$. For any $i \in I$ let $u_i := t_i + \mathfrak{m}$, then $A/\mathfrak{m} = F[U]$. And as $\mathfrak{m}$ is maximal, this makes $F[U]$ a field. By assumption (h) there is an isomorphism

$$\Phi \;:\; A\big/_{\mathfrak{m}} \xrightarrow{\sim} F$$

Let $x_i := \Phi(u_i) \in F$ then we find $\Phi(t_i - x_i + \mathfrak{m}) = \Phi(t_i + \mathfrak{m}_i) - \Phi(x_i 1_A + \mathfrak{m}) = \Phi(u_i) - x_i\Phi(1_A + \mathfrak{m}) = x_i - x_i = 0_F$. As Φ is injective we conclude $t_i - x_i + \mathfrak{m} = 0 + \mathfrak{m}$ and thereby $t_i - x_i \in \mathfrak{m}$. As this is true for any $i \in I$, we have $\mathfrak{m}_x \subseteq \mathfrak{m}$. But F was assumed to be a field and hence $\mathfrak{m}_x$ is maximal, such that we get $\mathfrak{m}_x = \mathfrak{m}$. In particular $x \in \mathbb{V}(\mathfrak{m}_x) = \mathbb{V}(\mathfrak{m}) \subseteq \mathbb{V}(\mathfrak{a})$ such that $\mathbb{V}(\mathfrak{a}) \neq \emptyset$.

By now we have established the equivalencies of (b) to (h) and all of the proves have been more or less straightforward. Time to bring (i) into the fold, we will see that this already requires some more effort:

- The direction (i) $\implies$ (g) is clear: If $\mathfrak{a} = A$, then $1_A \in \mathfrak{a}$ and hence $\mathbb{V}(\mathfrak{a}) \subseteq \mathbb{V}(1_A) = \emptyset$. Conversely consider $\mathfrak{a} \trianglelefteq_{\mathrm{i}} A$ with $\mathbb{V}(\mathfrak{a}) = \emptyset$, then $\sqrt{\mathfrak{a}} = \mathbb{IV}(\mathfrak{a}) = \mathbb{I}(\emptyset) = A$ and thereby $1_A \in \sqrt{\mathfrak{a}}$. That is $1_A^n \in \mathfrak{a}$ for some $n \in \mathbb{N}$ which implies $1_A \in \mathfrak{a}$ and thereby $\mathfrak{a} = A$.

- So we finally set out for (d) $\implies$ (i), where we know that F is an algebraically closed field, as (d) implies (b). Note that the assumption (d) can be put as: A is geometric. If I is infinite, then by (8.59.(iv)) we know, that $A[s]$ is geometric, too. If I is finite, say $I = 1 \ldots n$, then $A[s] = A[s] = F[s, t_1, \ldots, t_n]$ is geometric in itself, because of (8.59.(iii)). So in both cases we get from (d), that $A[s]$ is geometric, too. That is $A[s]$ satisfies property (d) and we already know that this is equivalent to property (g). That is we have (g) for $A[s]$, as well.

 With this knowledge in mind, we can use *Rabinowitsch's trick*, which still works like charm, after all these years: As F is a reduced ring (even a field) we have $\sqrt{\mathfrak{a}} \subseteq \mathbb{IV}(\mathfrak{a})$ according to (8.58.(iv)). Thus we only need to check the converse inclusion, which is

$$\mathbb{IV}(\mathfrak{a}) \quad = \quad \{\, f \in A \mid \forall\, x \in \mathbb{V}(\mathfrak{a}) : f(x) = 0 \,\} \quad \subseteq \quad \sqrt{\mathfrak{a}}$$

 Note that the condition $\forall\, x \in \mathbb{V}(\mathfrak{a}) : f(x) = 0$ is equivalent to saying $\mathbb{V}(\mathfrak{a}) \subseteq \mathbb{V}(f)$. Now assume that f is such a polynomial. Then we introduce a new indeterminate s to the polynomial

ring $A = F[t_i \mid i \in I]$ and for any $a \in \mathfrak{a}$ we define the following polynomials in $A[s]$

$$\overline{a}(s,t) \;:=\; a(t) \quad \text{and} \quad b(s,t) \;:=\; 1 - s\,f(t)$$

We now claim that the algebraic set of all these polynomials is empty - that is

$$\mathbb{V}(\mathfrak{b}) \;=\; \emptyset \quad \text{where} \quad \mathfrak{b} \;:=\; \langle \{\, \overline{a} \mid a \in \mathfrak{a} \,\} \cup \{\, b \,\} \rangle \;\trianglelefteq_{\mathrm{i}}\; A[s]$$

In fact assume that $z = (x,y) \in F \times F^I$ was contained in $\mathbb{V}(\mathfrak{b})$. Then by construction all the $\overline{a}$ would vanish on z. As $0 = \overline{a}(z) = a(y)$ this would imply $y \in \mathbb{V}(\mathfrak{a}) \subseteq \mathbb{V}(f)$ such that

$$0 \;=\; b(z) \;=\; 1 - xf(y) \;=\; 1 - x \cdot 0 \;=\; 1$$

From this contradiction we get $\mathbb{V}(\mathfrak{b}) = \emptyset$ and since (we have for this argued above) $A[s]$ satisfies property (g) again, this means $\mathfrak{b} = A[s]$ and hence there are polynomials $g_1, \ldots, g_r, h \in A[s]$ and $a_1, \ldots, a_r \in \mathfrak{a}$ such that

$$1 \;=\; g_1\,a_1 + \cdots + g_r\,a_r + h \cdot (1 - s\,f)$$

We now map $A[s] \to \mathrm{QUOT}(A)$ by substituting $s \mapsto 1/f$. If the insert this equation into this map $1 - s\,f$ vanishes and we can multiply with a sufficiently high power $k \in \mathbb{N}$ to clear denominators to finally find

$$f^k \;=\; \widetilde{g}_1\,a_1 + \cdots + \widetilde{g}_r\,a_r$$

where $\widetilde{g}_i(t) = f^k(t) \cdot g_i(\frac{1}{f(t)}, t) \in A$ now are polynomials of A. In other words, f is contained in the radical of $\mathfrak{a}$, which had to be shown.

Altogether we have established the equivalencies of (b) to (i) and it remains to tackle (a). This is where the real work begins: The proof for (a) $\implies$ (d) is a generalization of the proof found in M. Brodmann, Algebraische Geometrie for $F = \mathbb{C}$ and the converse direction is due to S. Lang.

- We start with (a) $\implies$ (d): If I is finite, then $A = F[t_i \mid i \in I]$ is geometric, according to (8.59.(iii)) and this already is property (d). So we only have to consider the case, that I is infinite: By definition any polynomial $f \in A = F[t_i \mid i \in I]$ is an F-linear combination over the monomials t^α where $\alpha \in \mathbb{N}^{\oplus I}$. However, as I is infinite

$$|\mathbb{N}^{\oplus I}| \;=\; \max\{\, |\mathbb{N}|, |I| \,\} \;=\; |I|$$

We can choose any well-ordering on I and use the bijection $I \longleftrightarrow \mathbb{N}^{\oplus I} : i \mapsto \alpha_i$ to install a total order $\alpha_i \leq \alpha_j \;:\Longleftrightarrow\; i \leq j$. This need not be a monomial order, as this will not be required for the proof. Nevertheless, we may define the degree of a polynomial $f \in A$ in the obvious way

$$\deg(f) \;:=\; \max\Big\{\, \alpha \in \mathbb{N}^{\oplus I} \mid f[\alpha] \neq 0 \,\Big\}$$

If now $\beta \in \mathbb{N}^{\oplus I}$ is any multi-index then clearly $\{\, t^\alpha \mid \alpha \leq \beta \,\}$ corresponds to a subset of I. Hence the subspace of A generated by this set has dimension $|I|$, at most:

$$\Omega_\beta \;:=\; \{\, f \in A \mid \deg(f) \leq \beta \,\}$$

- Now consider some maximal ideal $\mathfrak{m} \trianglelefteq_{\mathrm{i}} A$. We need to show that $\mathfrak{m}$ belongs to some point $x = (x_i) \in F^I$. But by the maximality of $\mathfrak{m}_x$, it suffices to show $\mathfrak{m}_x \subseteq \mathfrak{m}$, which can be put as

$$\forall\, i \in I \;\; \exists\, x_i \in F \;\; : \;\; t_i - x_i \in \mathfrak{m}$$

Assume this was false, i.e. there was some $j \in I$ such that for any $z \in F$ we would get $t_j - z \notin \mathfrak{m}$. Formally the assumption for this j reads as

$$\forall\, z \in F \;\; : \;\; t_j - z \notin \mathfrak{m}$$

As $\mathfrak{m}$ is maximal this implies $\mathfrak{m} + (t_j - z)A = A$ and hence (for any $z \in F$) we may find polynomials $m^z \in \mathfrak{m}$ and $g^z \in A$ such that

$$\forall\, z \in F \;\; : \;\; m^z + (t_j - z)g^z \;=\; 1$$

Every polynomial g^z has a degree and hence F may be decomposed into a disjoint union of the following subsets

$$F \;\; = \;\; \bigsqcup_{i \in I} \{\, z \in F \mid \deg(g^z) = \alpha_i \,\}$$

If all these sets $F_i := \{\, z \in F \mid \deg(g^z) = \alpha_i \,\}$ would satisfy $|F_i| \leq |I|$ then there would be surjective maps $s_i : I \twoheadrightarrow F_i$ and thereby a surjective map $I \times I \twoheadrightarrow F : (h,i) \mapsto s_i(h)$. Yet as I is infinite we have $|I \times I| = |I| < |F|$ by assumption and (0.38.(iv)). Hence there cannot be a surjective map from $I \times I$ onto F. We conclude that there must be some $i \in I$ such that $|F_i| > |I|$. Let $\beta := \alpha_i$ and $Z := F_i$ for this $i \in I$, that is

$$Z \;\; := \;\; \{\, z \in F \mid \deg(g^z) = \beta \,\} \quad \text{satisfies} \quad |Z| \;>\; |I|$$

As we have seen Ω_β is an F-vectorspace of dimension at most $|I|$. If some of the g^z where $z \in Z$ were identical, then we could skip the next step and continue with the next linear relation, right away. If all the g^z where $z \in Z$ are distinct, then the set $\{\, g^z \mid z \in Z \,\}$ has cardinality $|Z| > |I| \geq \dim(\Omega_\beta)$. Thus the g^z have to satisfy a linear relation, that is there are pairwise distinct elements $z_1, \ldots, z_r \in Z$ and coefficients $\lambda_1, \ldots, \lambda_r \in F^*$ such that

$$\sum_{p=1}^{r} \lambda_p\, g^{z_p} \;\; = \;\; 0$$

We now define a specific polynomial $g \in F[t_j] \subseteq A$ in the one variable t_j over F

$$g \;\; := \;\; \sum_{p=1}^{r} \lambda_p \prod_{q \neq p} (t_j - z_q) \;\; \in \;\; F[t_j] \;\; \subseteq \;\; A$$

By construction we have $g(z_1) = \lambda_1 (z_1 - z_2) \ldots (z_1 - z_r) \neq 0$ and hence g is non-zero itself. We now claim that this polynomial is nevertheless contained in the ideal $\mathfrak{m}$

$$g \;\; = \;\; \sum_{p=1}^{r} \lambda_p \prod_{q \neq p} (t_j - z_q)$$

$$
\begin{aligned}
&= \sum_{p=1}^{r} \lambda_p [m^{z_p} + (t_j - z_p) g^{z_p}] \prod_{q \neq p} (t_j - z_q) \\
&= \sum_{p=1}^{r} \left[\lambda_p \prod_{q \neq p} (t_j - z_q) \right] m^{z_p} + \left[\sum_{p=1}^{r} \lambda_p \, g^{z_p} \right] \prod_{q=1}^{r} (t_j - z_q) \\
&= \sum_{p=1}^{r} \left[\lambda_p \prod_{q \neq p} (t_j - z_q) \right] m^{z_p} + 0 \quad \in \quad \mathfrak{m}
\end{aligned}
$$

That is, we have $g \in \mathfrak{m}$, if $g \in F$ was constant, then (as also $g \neq 0$) we had $g \in F^* = A^*$. But this cannot be, as $g \in \mathfrak{m}$ and $\mathfrak{m} \neq A$. In fact, as $\mathfrak{m}$ is maximal, it is a prime ideal and hence some prime factor of $g \in F[t_j]$ is contained in $\mathfrak{m}$. But as F is algebraically closed and $g \notin F$, the prime factors of g are of the form $t_j - z$ for some $z \in F$, in contradiction to $t_j - z \notin \mathfrak{m}$ for any $z \in F$.

- We turn our attention to (d) $\implies$ (a) now: We already know that (d) implies F to be algebraically closed, due to (8.58.(ii)) so it only remains to prove $|I| < |F|$. If I is finite, then $|I| < |F|$ is clear, as an algebraically closed field always is infinite. So from now on we assume, that I is infinite: Fix any $j \in I$, as I is infinite we have $|I \setminus \{j\}| = |I|$ and thereby there is a subset $H \subseteq I \setminus \{j\}$ such that $H \longleftrightarrow F : i \mapsto a_i$. We now define a homomorphism of F-algebras $\varphi : A \to F(s)$, by expansion of

$$
\begin{aligned}
\varphi(t_i) &:= 0 \quad \text{for} \quad i \in I \setminus \big(H \cup \{j\}\big) \\
\varphi(t_i) &:= s \quad \text{for} \quad i = j \\
\varphi(t_i) &:= \frac{1}{s - a_i} \quad \text{for} \quad i \in H
\end{aligned}
$$

We first have to check, that φ is surjective: As F is algebraically closed any polynomial $p(s) \in F[s]$ splits into linear factors, but as we have enumerated F using the index set H, we may write it in the form

$$
p(s) \quad = \quad \lambda \, (s - a)^{\alpha} \quad := \quad \lambda \prod_{i \in H} (s - a_i)^{\alpha_i}
$$

with only finitely many $\alpha_i \in \mathbb{N}$ being non-zero. Therefore any rational function p/q, where p, $q \in F[s]$ and $q \neq 0$, can be written in the following form, where $k_i \in \mathbb{Z}$ and only finitely many k_i are non-zero

$$
\frac{p(s)}{q(s)} \quad = \quad \lambda \prod_{i \in H} (s - a_i)^{k_i}
$$

By construction of φ it is clear, that any polynomial $f(t_j) \in F[t_j] \subseteq A$ is simply mapped to $f(s) \in F(s)$. Likewise any monomial $t^{\beta} \in F[t_i \mid i \in H] \subseteq A$ where $\beta \in \mathbb{N}^{\oplus H}$ is mapped to $1/(s - a)^{\beta}$. Recall that we aim to prove the surjectivity of φ: Given $p/q \in F[s]$, write p/q in the form above and pick up α and $\beta \in \mathbb{N}^{\oplus H}$ such that $k_i = \alpha_i - \beta_i$ for any $i \in H$ (and $\alpha_i = 0 = \beta_i$ for $k_i = 0$). Then we find polynomials $f := \lambda \prod_i (t_j - a_i)^{\alpha_i} \in F[t_j] \subseteq A$ and $g := t^{\beta} \in F[t_i \mid i \in H] \subseteq A$ such that $fg \in A$ is mapped to $p/q \in F(s)$ under φ, since

$$
\varphi\left(\lambda \prod_{i \in H} (t_j - a_i)^{\alpha_i} \cdot t^{\beta} \right) \; = \; \lambda \prod_{i \in H} (s - a_i)^{\alpha_i} \cdot \frac{1}{(s - a)^{\beta}} \; = \; \lambda \prod_{i \in H} \frac{(s - a_i)^{\alpha_i}}{(s - a_i)^{\beta_i}} \; = \; \frac{p(s)}{q(s)}
$$

As p/q have been arbitrary φ is surjective and if we let $\mathfrak{m} := \ker(\varphi)$ we therefore find an isomorphism

$A/\mathfrak{m} \xrightarrow{\sim} F(s)$. As $F(s)$ is a field, $\mathfrak{m}$ is a maximal ideal. Now by (d) we find $\mathfrak{m} = \mathfrak{m}_x$ for some $x \in F^I$, in particular $t_i - x_i \in \mathfrak{m}$ for some $i \in H$. By construction this means

$$0 \;=\; \varphi(t_i - x_i) \;=\; \frac{1}{s - a_i} - x_i \;=\; \frac{1 - x_i s + x_i a_i}{s - a_i}$$

This yields $1 - x_i s + x_i a_i = 0$ and by comparing the coefficients of this polynomial in s, we get $x_i = 0$ and $0 = 1 + x_i a_i = 1$. But $0 = 1$ is an obvious contradiction to the assumption $|F| \leq |I|$.

□

Proof of (8.62):
By assumption F satisfies property (a) in theorem (8.60). So if we start with $\mathfrak{a} \in \operatorname{Srad}(A)$ then by property (i) in (8.60) we get $\mathbb{IV}(\mathfrak{a}) = \sqrt{\mathfrak{a}} = \mathfrak{a}$. Conversely if $X = \mathbb{V}(\mathfrak{a})$ is an algebraic set, then $\mathbb{I}(X)$ is a radical ideal, as any field is reduced. And due to the Galois connection property we get $\mathbb{VI}(X) = \mathbb{VIV}(\mathfrak{a}) = \mathbb{V}(\mathfrak{a}) = X$. In effect $\mathbb{V}$ and $\mathbb{I}$ are well-defined and mutually inverse maps.

If F is not algebraically closed, then property (b) in (8.60) has to fail, according to (8.58.(ii)). That is (d) has to fail and hence there are maximal ideals of A that do not correspond to a point $x \in F^I$. And if $|F| \leq |I|$, then we would be able to construct a maximal ideal $\mathfrak{m} \trianglelefteq_{\mathfrak{i}} A$ such that $\mathbb{V}(\mathfrak{m}) = \emptyset = \mathbb{V}(A)$, as we have seen in the proof of (b) $\implies$ (a) of theorem (8.60). Thus the correspondence fails in this case, too. □

Proof of (8.63):

(i) For any $x \in R^J$ let us abbreviate $\check{x} := \pi_I^J(x)$ and $\widehat{\mathfrak{a}} := \mathfrak{a}\,R[J]$. Then we start by decoding what it means that $x \in (\pi_I^J)^{-1}(\mathbb{V}(\mathfrak{a}))$. First of all this is $\check{x} \in \mathbb{V}(\mathfrak{a})$ and this again means $a(\check{x}) = 0$ for any $a \in \mathfrak{a}$. That is we have to prove that the following equivalence holds for all $x \in R^J$

$$\forall\, f \in \widehat{\mathfrak{a}} : f(x) = 0 \quad\Longleftrightarrow\quad \forall\, a \in \mathfrak{a} : a(\check{x}) = 0$$

In the direction " $\Longleftarrow$ " we are given some $a \in \mathfrak{a}$ and need to show that $a(\check{x}) = 0$. But letting $f = \widehat{a} := \iota_I^J(a) \in \mathfrak{a}\,R[J] = \widehat{\mathfrak{a}}$, this becomes apparent

$$a(\check{x}) \;=\; f(x) \;=\; 0$$

For the converse implication we are given $f \in \widehat{\mathfrak{a}}$ and need to show $f(x) = 0$. That is there are $f_i \in R[J]$ and $a_i \in \mathfrak{a}$ such that for $\widehat{a}_i := \iota_I^J(a_i)$ we get $f = f_1\,\widehat{a}_1 + \cdots + f_r\,\widehat{a}_r$. As above, it is clear, that $\widehat{a}_i(x) = a_i(\check{x})$ and hence

$$f(x) \;=\; f_1(x)\,a_1(\check{x}) + \cdots + f_r(x)\,a_r(\check{x}) \;=\; 0$$

(ii) Let us denote $\widehat{X} := (\pi_I^J)^{-1}(X) \subseteq R^J$ then we have to show $\mathbb{I}(\widehat{X}) = \mathbb{I}(X)\,R[J]$. For $I = J$ we have $\widehat{X} = X$ and $\mathbb{I}(X)\,R[J] = \mathbb{I}(X)$ so the claim is satisfied trivially. Also, in case $X = \emptyset$ we have $\widehat{X} = \emptyset$ and $\mathbb{I}(X) = \mathbb{I}(\emptyset) = R[I]$ such that $\mathbb{I}(\widehat{X}) = R[J] = \mathbb{I}(X)\,R[J]$. Thus we only need to consider $I \subset J$ and $X \neq \emptyset$. We first deal with the inclusion $\mathbb{I}(X)\,R[J] \subseteq \mathbb{I}(\widehat{X})$: As $\mathbb{I}(X)\,R[J]$ is generated by $\{\, \widehat{a} \mid a \in \mathbb{I}(X) \,\}$, where $\widehat{a} := \iota_I^J(a)$, it suffices to show $\widehat{a} \in \mathbb{I}(\widehat{X})$ for any $a \in \mathbb{I}(X)$.

But by construction $\widehat{a}(x) = a(\check{x}) = 0$ for any $x \in \widehat{X}$ with $\check{x} := \pi_I^J(x) \in X$. Thus we have

$$\mathbb{I}(X)\, R[J] \quad \subseteq \quad \mathbb{I}\big(\widehat{X}\big)$$

For the converse inclusion we have to regard any $f \in R[J]$ such that for any $x \in \widehat{X}$ we get $f(x) = 0$ and have to show $f \in \mathbb{I}(X)\, R[J]$. Fix any $\check{x} \in X$ and any $y \in R^{J \setminus I}$ then $x := (\check{x}, y) \in \widehat{X}$ and thereby $f(x) = 0$. Let $S := R[I]$ and $H := J \setminus I$. Note that $H \neq \emptyset$, as $I \subset J$. Then we write $f \in R[J]$ as a polynomial in $f \in S[H]$, that is

$$f \;=\; \sum_{(\alpha,\beta) \in \mathbb{N}^{\oplus J}} f[\alpha,\beta]\, t^{(\alpha,\beta)} \;=\; \sum_{\beta \in \mathbb{N}^{\oplus H}} \left(\sum_{\alpha \in \mathbb{N}^{\oplus I}} f[\alpha,\beta]\, t^{\alpha} \right) t^{\beta}$$

Then we turn our attention to $g(t) := f(\check{x}, t) \in R[H]$. By assumption on f we have $g(y) = f(x) = 0$ for any $y \in R^H$. And as R is an infinite integral domain this means $g = 0$. That is for any $\beta \in \mathbb{N}^{\oplus H}$ we have $f_\beta(\check{x}) = 0$ where

$$f_\beta \;:=\; \sum_{\alpha \in \mathbb{N}^{\oplus I}} f[\alpha,\beta]\, t^{\alpha} \;\in\; R[I]$$

As $\check{x} \in X$ has been arbitrary, this means $f_\beta \in \mathbb{I}(X)$. But by construction there are finitely many $\beta \in \mathbb{N}^{\oplus H}$ such that f can be written as $f = \sum_\beta f_\beta\, t^\beta$. Then, as any $f_\beta \in \mathbb{I}(X)$ we get $f \in \mathbb{I}(X)\, R[J]$ and thereby we also have the converse inclusion.

(iii) The inclusion $\sqrt{\mathfrak{u}} \subseteq \mathbb{I}\,\mathbb{V}(\mathfrak{u})$ is generally true, for any reduced ring R. For the converse inclusion note that any algebraically closed field already is an infinite integral domain. By (i) we have $\mathbb{V}(\mathfrak{u}) = (\pi_I^J)^{-1}(\mathbb{V}(\mathfrak{a}))$ and (ii) turns this into

$$\begin{aligned} \mathbb{I}\,\mathbb{V}(\mathfrak{u}) \;&=\; \mathbb{I}\left(\left(\pi_I^J\right)^{-1} (\mathbb{V}(\mathfrak{a})) \right) \;=\; \mathbb{I}\,\mathbb{V}(\mathfrak{a})\, R[J] \\ &=\; \sqrt{\mathfrak{a}}\, R[J] \;\subseteq\; \sqrt{\mathfrak{a}\, R[J]} \;=\; \sqrt{\mathfrak{u}} \end{aligned}$$

□

8.6 Galois Theory

8.7 Krull Dimension

The notion of the dimension of a commutative ring is inspired by algebraic geometry: E.g. a flying carpet is a 2-dimensional object, this can be seen in two ways: (1) at any point, the tangential space is a plane or (2) we can build up the dimension iteratively: The flying carpet contains the image of a plane, which contains the image of a line, which contains the image of a point. As in each step the dimension is increased by 1 and as we start with dimension 0 (of a point), we end up at 2 again. Hence in algebraic geometry (without going into details), the dimension can be defined by chains of irreducible subsets - the longer the chain can be, the higher the dimension. As prime ideals correspond to irreducible subsets (in a order-reversing way), we can measure the length of the chain in the ring of regular functions of the variety. The theory we are about to present here is about lengths of chains of prime ideals, as they can be better controlled, than irreducible subsets. It will be the perfect tool for algebraic geometry.

This sub-section boasts several theorems of great renown: After some preleminary results we provide going-up and down. We then compare the Krull dimension with the transcendence degree of an algebra, by continuing the Noetherian normalisation theorem. And finally we aim for Krulls principal ideal theorem, which gives an upper on the number of generators of an ideal in a noetherian ring. These theorems are hard-earned, step by step we wall in the truth until it finally cannot elude us any more. Alas, the sweetest fruits are the hardest to pluck.

(8.64) Definition:
Let $(R,+,\cdot)$ be a commutative ring, then a tuple $(\mathfrak{p}_0,\ldots,\mathfrak{p}_n)$ is said to be a **chain of prime ideals** (which we usually abbreviate by **CPI** iff it satisfies the following properties (1), (2) and (3), where

(1) For any $k \in 0\ldots n$ $\mathfrak{p}_k \trianglelefteq_{\mathfrak{i}} R$ is a prime ideal

(2) For any $k \in 1\ldots n$ we have $\mathfrak{p}_{k-1} \subseteq \mathfrak{p}_k$

(3) For any $k \in 1\ldots n$ we have $\mathfrak{p}_{k-1} \neq \mathfrak{p}_k$

We denote the set of all chains of prime ideals in R by $\mathrm{CPI}(R)$. An if $\mathfrak{p}$ and $\mathfrak{q}$ are prime ideals of R, then the set of all chains of prime ideals that start in $\mathfrak{p}$ is denoted by $\mathrm{CPI}_{\mathfrak{p}}(R)$. The set of all chains of prime ideals that end in $\mathfrak{q}$ is denoted by $\mathrm{CPI}^{\mathfrak{q}}(R)$. Formally

$$\begin{aligned}
\mathrm{CPI}(R) &:= \{\,(\mathfrak{p}_0,\ldots,\mathfrak{p}_n) \mid (1),(2),(3)\,\}\\
\mathrm{CPI}_{\mathfrak{p}}(R) &:= \{\,(\mathfrak{p}_0,\ldots,\mathfrak{p}_n) \in \mathrm{CPI}(R) \mid \mathfrak{p}_0 = \mathfrak{p}\,\}\\
\mathrm{CPI}^{\mathfrak{q}}(R) &:= \{\,(\mathfrak{p}_0,\ldots,\mathfrak{p}_n) \in \mathrm{CPI}(R) \mid \mathfrak{p}_n = \mathfrak{q}\,\}\\
\mathrm{CPI}^{\mathfrak{q}}_{\mathfrak{p}}(R) &:= \{\,(\mathfrak{p}_0,\ldots,\mathfrak{p}_n) \in \mathrm{CPI}(R) \mid \mathfrak{p}_0 = \mathfrak{p} \text{ and } \mathfrak{p}_n = \mathfrak{q}\,\}
\end{aligned}$$

Finally, if $\mathcal{P} = (\mathfrak{p}_0,\ldots,\mathfrak{p}_m)$ and $\mathcal{Q} = (\mathfrak{q}_0,\ldots,\mathfrak{q}_n) \in \mathrm{CPI}(R)$ are any two chains of prime ideals in R, then we introduce a partial order $\leq$ on $\mathrm{CPI}(R)$, by letting $\mathcal{P} \leq \mathcal{Q}$, iff one of the following two equivalent conditions is satisfied

(a) $\{\,\mathfrak{p}_0,\ldots,\mathfrak{p}_m\,\} \subseteq \{\,\mathfrak{q}_0,\ldots,\mathfrak{q}_n\,\}$

(b) $\exists\, j : 0\ldots m \hookrightarrow 0\ldots n$ injective, such that $\forall\, i \in 0\ldots m$ we get $\mathfrak{p}_i = \mathfrak{q}_{j(i)}$

Prob If (a) then any $\mathfrak{p}_i \in \{\, \mathfrak{q}_0, \ldots, \mathfrak{q}_n \,\}$. That is there is some $j(i) \in 0 \ldots n$ such that $p_i \in \mathfrak{q}_{j(i)}$. And as the $\mathfrak{p}_i$ are pairwise distinct, by (3), the map $j : i \mapsto j(i)$ is injective. So we got (b). If conversely (b) then for any $i \in 0 \ldots m$ we get $\mathfrak{p}_i = \mathfrak{q}_{j(i)} \in \{\, \mathfrak{q}_0, \ldots, \mathfrak{q}_n \,\}$, which is (a). Thereby it is clear, that $\leq$ inherits the properties of a partial order from $\subseteq$ in property (a).

(8.65) Remark:

(i) Consider a commutative ring $(R, +, \cdot)$ and a prime ideal $\mathfrak{p} \in \operatorname{Spec}(R)$. By the correspondence theorem of prime ideals (1.71) the prime ideals of $R/\mathfrak{p}$ correspond to the prime ideals of R that contain $\mathfrak{p}$. And as this correspondence respects the inclusion $\subseteq$ it is clear, that we get the following one-to-one correspondence of chains of prime ideals

$$\begin{array}{rcl} \{\, \mathcal{P} \in \operatorname{CPI}(R) \mid \mathfrak{p} \subseteq \mathfrak{p}_0 \,\} & \longleftrightarrow & \operatorname{CPI}\left(R \Big/ \mathfrak{p}\right) \\ \mathcal{P} = (\mathfrak{p}_0, \ldots, \mathfrak{p}_n) & \mapsto & \left(\mathfrak{p}_0 \Big/ \mathfrak{p}, \ldots, \mathfrak{p}_n \Big/ \mathfrak{p}\right) \end{array}$$

(ii) Likewise by (2.129) there is a one to one correspondence between the prime ideals of the localisation $R_\mathfrak{p}$ and the prime ideals of R that are contained in $\mathfrak{p}$, where $\mathfrak{p}_k R_\mathfrak{p} = \{\, a/u \in R_\mathfrak{p} \mid a \in \mathfrak{p}_k, u \in R \setminus \mathfrak{p} \,\}$. Recall that $R_\mathfrak{p}$ is a local ring with maximal ideal $\mathfrak{p}R_\mathfrak{p}$ according to (2.138). This correspondence also respects inclusions and hence grants a one-to-one correspondence of chains of prime ideals

$$\begin{array}{rcl} \{\, \mathcal{P} \in \operatorname{CPI}(R) \mid \mathfrak{p}_n \subseteq \mathfrak{p} \,\} & \longleftrightarrow & \operatorname{CPI}(R_\mathfrak{p}) \\ \mathcal{P} = (\mathfrak{p}_0, \ldots, \mathfrak{p}_n) & \mapsto & (\mathfrak{p}_0 R_\mathfrak{p}, \ldots, \mathfrak{p}_n R_\mathfrak{p}) \end{array}$$

(iii) Let us combine (i) and (ii): If $\mathfrak{p} \subseteq \mathfrak{q} \in \operatorname{Spec}(R)$ are nested primes of R, then we take $Q := R/\mathfrak{p}$ a quotient ring of R, that is an integral domain. By (i) $\overline{\mathfrak{q}} := \mathfrak{q}/\mathfrak{p}$ is a prime ideal in Q and thereby we can take to the local ring $Q_{\overline{\mathfrak{q}}}$ whose maximal ideal is given to be $\overline{\mathfrak{q}} Q_{\overline{\mathfrak{q}}}$. And we obtain a one-to-one correspondence of chains of prime ideals

$$\begin{array}{rcl} \operatorname{CPI}^{\mathfrak{q}}_{\mathfrak{p}}(R) & \longleftrightarrow & \operatorname{CPI}(Q_{\overline{\mathfrak{q}}}) \\ (\mathfrak{p}_0, \ldots, \mathfrak{p}_n) & \mapsto & \left(\mathfrak{p}_0 \Big/ \mathfrak{p}Q_{\overline{\mathfrak{q}}}, \ldots, \mathfrak{p}_n \Big/ \mathfrak{p}Q_{\overline{\mathfrak{q}}}\right) \end{array}$$

(8.66) Definition: (viz. 1271)
Let $(R, +, \cdot)$ be a commutative ring again, then a CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ of R is said to be **saturated**, iff it cannot be extended to a longer chain by inserting more prime ideals. That is iff it satisfies one of the following two conditions

(a) The chain $(\mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ is a maximal element of $\operatorname{CPI}^{\mathfrak{q}}_{\mathfrak{p}}(R)$, where $\mathfrak{p} = \mathfrak{p}_0$ and $\mathfrak{q} = \mathfrak{p}_m$. That is for any CPI $(\mathfrak{q}_0, \ldots, \mathfrak{q}_n)$ that satisfies $\mathfrak{q}_0 = \mathfrak{p}_0$ and $\mathfrak{q}_n = \mathfrak{p}_m$ we get

$$(\mathfrak{p}_0, \ldots, \mathfrak{p}_m) \leq (\mathfrak{q}_0, \ldots, \mathfrak{q}_n) \quad \Longrightarrow \quad (\mathfrak{p}_0, \ldots, \mathfrak{p}_m) = (\mathfrak{q}_0, \ldots, \mathfrak{q}_n)$$

(b) For any prime ideal $\mathfrak{p} \in \operatorname{Spec}(R)$ and any index $k \in 1 \ldots m$ we have the following implication

$$\mathfrak{p}_{k-1} \subseteq \mathfrak{p} \subseteq \mathfrak{p}_k \quad \Longrightarrow \quad \mathfrak{p}_{k-1} = \mathfrak{p} \text{ or } \mathfrak{p} = \mathfrak{p}_k$$

And $(\mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ is said to be **maximal**, iff it cannot be extended to a longer chain by inserting or appending prime ideals at any position. That is iff it satisfies one of the following two conditions

(a) The chain $(\mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ is a maximal element of $\mathrm{CPI}(R)$. That is for any CPI $(\mathfrak{q}_0, \ldots, \mathfrak{q}_n)$ we get

$$(\mathfrak{p}_0, \ldots, \mathfrak{p}_m) \leq (\mathfrak{q}_0, \ldots, \mathfrak{q}_n) \quad \Longrightarrow \quad (\mathfrak{p}_0, \ldots, \mathfrak{p}_m) = (\mathfrak{q}_0, \ldots, \mathfrak{q}_n)$$

(b) The chain $(\mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ satisfies the following three properties: (1) it is saturated, (2) $\mathfrak{p}_m$ is a maximal ideal of R and (3) $\mathfrak{p}_0$ is a minimal prime ideal of R. That is for any prime ideal $\mathfrak{p} \in \mathrm{Spec}(R)$ we get $\mathfrak{p} \subseteq \mathfrak{p}_0 \implies \mathfrak{p} = \mathfrak{p}_0$.

(8.67) Remark:
If $(R, +, \cdot)$ is any commutative ring $\mathfrak{p}$ and $\mathfrak{q} \in \mathrm{Spec}(R)$ are prime ideals and $\mathcal{Q} = (\mathfrak{q}_0, \ldots, \mathfrak{q}_n)$ is a CPI of R, with $\mathfrak{p} = \mathfrak{q}_0$ and $\mathfrak{q}_n = \mathfrak{q}$. If $\mathcal{P}$ is of maximal length with this property, that is

$$\ell(\mathcal{Q}) \quad = \quad \max\{\, \ell(\mathcal{P}) \in \mathbb{N} \mid \exists\, \mathcal{P} \in \mathrm{CPI}_{\mathfrak{p}}^{\mathfrak{q}}(R) \,\}$$

Then $\mathcal{Q}$ obviously is saturated, as any CPI that truly extends $\mathcal{Q}$ would have to exceed $\mathcal{Q}$ in length. The converse need not be true, however: There may be CPI from $\mathfrak{p}$ to $\mathfrak{q}$ that are longer than a given saturated CPI. Counter-examples are not easy to find, but Nagata managed to do so.

(8.68) Definition:
Once more let $(R, +, \cdot)$ be a commutative ring and $\mathcal{P} = (\mathfrak{p}_0, \ldots, \mathfrak{p}_n)$ be a CPI in R. Then we call n the **length** of $\mathcal{P}$ and denote it by $\ell(\mathcal{P}) := n$. Now if $R \neq 0$ is non-zero, then we define its **Krull-dimension** [or simply its *dimension*] to be the maximal length of any CPI contained in R. If the length is unbound, then the dimension of R is infinite, formally

$$\mathrm{kdim}(R) \quad := \quad \sup\{\, \ell(\mathcal{P}) \mid \mathcal{P} \in \mathrm{CPI}(R) \,\} \quad \in \quad \mathbb{N} \cup \{\infty\}$$

If $R \neq 0$, then $\mathrm{kdim}(R) \geq 0$, as there always is at least one maximal ideal contained in R. And in case $R = 0$ we specifically define $\mathrm{kdim}(R) := -1$. And for a fixed prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$, we define the **height** of $\mathfrak{p}$ to be the maximal length of a CPI, that terminates in $\mathfrak{p}$:

$$\mathrm{height}(\mathfrak{p}) \quad := \quad \sup\{\, \ell(\mathcal{P}) \mid \mathcal{P} \in \mathrm{CPI}^{\mathfrak{p}}(R) \,\} \quad \in \quad \mathbb{N} \cup \{\infty\}$$

For the ideal $\mathfrak{a} = R$ we specifically define $\mathrm{height}(R) = -1$. And for a proper ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ (that is $\mathfrak{a} \neq R$) there is a maximal ideal containing $\mathfrak{a}$, according to (2.4.(ii)) and hence we may define the **height** of $\mathfrak{a}$ to be the minimal height of a prime ideal containing $\mathfrak{a}$.

$$\mathrm{height}(\mathfrak{a}) \quad := \quad \inf\{\, \mathrm{height}(\mathfrak{p}) \mid \mathfrak{p} \in \mathrm{Spec}(R) \ \text{ with } \mathfrak{a} \subseteq \mathfrak{p} \,\} \quad \in \quad \mathbb{N} \cup \{\infty\}$$

Nota if $\mathfrak{a} = \mathfrak{p}$ is a prime ideal of R itself, then $\mathrm{height}(\mathfrak{a})$ in this sense equals $\mathrm{height}(\mathfrak{p})$ as a prime ideal. This is clear, as any prime ideal $\mathfrak{q}$ with $\mathfrak{a} \subseteq \mathfrak{q}$ already contains $\mathfrak{p} \subseteq \mathfrak{q}$ and hence $\mathrm{height}(\mathfrak{p}) \leq \mathrm{height}(\mathfrak{q})$. In case of doubt refer to (8.69.(vi)) below.

Nota recall the notation $\mathbb{V}(\mathfrak{a}) := \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p} \,\}$, which is a non-epmty set, as $\mathfrak{a} \neq R$. Using this we can rewrite the above definition, as $\mathrm{height}(\mathfrak{a}) = \min\{\, \mathrm{height}(\mathfrak{p}) \mid \mathfrak{p} \in \mathbb{V}(\mathfrak{a}) \,\}$. Some authors only allow prime ideals minimal over $\mathfrak{a}$, that is they define $\mathrm{height}(\mathfrak{a}) = \min\{\, \mathrm{height}(\mathfrak{p}) \mid \mathfrak{p} \in \mathbb{V}(\mathfrak{a})_* \,\}$. But we will see in (8.69.(vii)) below, that both definitions return the same result.

(8.69) Proposition: (viz. 1236)
Let $(R, +, \cdot)$ be any commutative ring and $\mathfrak{p} \in \mathrm{Spec}(R)$ be any prime ideal of R. Then the following statements are generally true

(i) If $\mathcal{P} \in \mathrm{CPI}(R)$ is a chain of prime ideals with $\ell(\mathcal{P}) = \mathrm{kdim}(R)$, then $\mathcal{P}$ is maximal.

(ii) If $(S, +, \cdot)$ is another commutative ring and $\varphi : S \twoheadrightarrow R$ is a surjective homomorphism of rings, then the Krull-dimension of R cannot exceed the Krull-dimension of S, that is

$$\mathrm{kdim}(R) \quad \leq \quad \mathrm{kdim}(S)$$

Nota If $\varphi : R \hookrightarrow S$ is an injective homomorphism of rings, than we cannot draw this conclusion. An easy counter-example is $\mathbb{Z} \hookrightarrow \mathbb{Q}$ where we have $\mathrm{kdim}(\mathbb{Z}) = 1 > 0 = \mathrm{kdim}(\mathbb{Q})$.

(iii) Any prime ideal $\mathfrak{p} \in \mathrm{Spec}(R)$ is a minimal prime (that is for any other $\mathfrak{p}' \in \mathrm{Spec}(R)$ we have the implication $\mathfrak{p}' \subseteq \mathfrak{p} \implies \mathfrak{p}' = \mathfrak{p}$) if and only if, it has $\mathrm{height}(\mathfrak{p}) = 0$. Formally that is

$$\mathrm{Smin}(R) \quad = \quad \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathrm{height}(\mathfrak{p}) = 0 \,\}$$

(iv) The Krull-dimension of $R/\mathrm{nil}(R)$ equals the Krull-dimension of R, that is we have the identity

$$\mathrm{kdim}\left(R \Big/ \mathrm{nil}(R) \right) \quad = \quad \mathrm{kdim}(R)$$

(v) By definition the dimension of R is the maximal height of a prime ideal of R. But this definition already yields the following identities

$$\begin{aligned} \mathrm{kdim}(R) \quad &= \quad \sup\{\, \mathrm{height}(\mathfrak{a}) \mid \mathfrak{a} \in \mathrm{Ideal}(R) \,\} \\ &= \quad \sup\{\, \mathrm{height}(\mathfrak{p}) \mid \mathfrak{p} \in \mathrm{Spec}(R) \,\} \\ &= \quad \sup\{\, \mathrm{height}(\mathfrak{m}) \mid \mathfrak{m} \in \mathrm{Smax}(R) \,\} \end{aligned}$$

(vi) If $\mathfrak{p}$, $\mathfrak{q}$ are any prime ideals of R with $\mathrm{height}(\mathfrak{q}) < \infty$ then we get the following implication

$$\mathfrak{p} \subset \mathfrak{q} \quad \Longrightarrow \quad \mathrm{height}(\mathfrak{p}) < \mathrm{height}(\mathfrak{q})$$

(vii) Let $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be any ideal and $\mathfrak{p} \in \mathrm{Spec}(R)$ be a prime ideal of R, such that $\mathfrak{a} \subseteq \mathfrak{p}$ and $\mathrm{height}(\mathfrak{a}) = \mathrm{height}(\mathfrak{p})$. Then $\mathfrak{p}$ already is a *minimal over* $\mathfrak{a}$ [that is for any $\mathfrak{p}' \in \mathrm{Spec}(R)$ with $\mathfrak{a} \subseteq \mathfrak{p}' \subseteq \mathfrak{p}$ we get $\mathfrak{p}' = \mathfrak{p}$]. Therefore, if $\mathfrak{a} \neq R$ is a proper ideal of finite height $\mathrm{height}(\mathfrak{a}) < \infty$, then we get

$$\mathrm{height}(\mathfrak{a}) \quad = \quad \min\{\, \mathrm{height}(\mathfrak{p}) \mid \mathfrak{a} \subseteq \mathfrak{p} \text{ minimal over } \mathfrak{a} \,\}$$

(viii) Let $\mathfrak{p}$, $\mathfrak{q} \in \operatorname{Spec}(R)$ be prime ideals and recall the notion that $\mathfrak{p}$ lies *directly under* $\mathfrak{q}$ iff (1) $\mathfrak{p} \subset \mathfrak{q}$ and (2) for any $\mathfrak{p}' \in \operatorname{Spec}(R)$ with $\mathfrak{p} \subseteq \mathfrak{p}' \subseteq \mathfrak{q}$ we get $\mathfrak{p}' = \mathfrak{p}$ or $\mathfrak{p}' = \mathfrak{q}$. We denote this by writing $\mathfrak{p} \subset_* \mathfrak{q}$. If now $(\mathfrak{p}_0, \ldots, \mathfrak{p}_n)$ is a CPI of R, such that $n = \operatorname{kdim}(R)$, then we have

(1) $\mathfrak{p}_0 \in \operatorname{Smin}(R)$ and $\mathfrak{p}_n \in \operatorname{Smax}(R)$

(2) $\forall\, k \in 1 \ldots n : \mathfrak{p}_{k-1} \subset_* \mathfrak{p}_k$

(3) $\forall\, k \in 0 \ldots n : \operatorname{height}(\mathfrak{p}_k) = k$

Likewise, if $(\mathfrak{p}_0, \ldots, \mathfrak{p}_r)$ is a CPI of R such that $r = \operatorname{height}(\mathfrak{p}_r)$, then we get the following properties:

(1) $\mathfrak{p}_0 \in \operatorname{Smin}(R)$

(2) $\forall\, k \in 1 \ldots r : \mathfrak{p}_{k-1} \subset_* \mathfrak{p}_k$

(3) $\forall\, k \in 0 \ldots r : \operatorname{height}(\mathfrak{p}_k) = k$

(ix) The height of $\mathfrak{p}$ in R equals the Krull-dimension of $R_{\mathfrak{p}}$ as a ring, that is we have the identity

$$\operatorname{kdim}(R_{\mathfrak{p}}) \quad = \quad \operatorname{height}(\mathfrak{p})$$

(x) If R is finite-dimensional, then so are the quotient ring $R/\mathfrak{p}$ and localisation $R_{\mathfrak{p}}$. More generally, for any ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ we have the following estimate of dimensions

$$\operatorname{kdim}\left(R \Big/ \mathfrak{a}\right) + \operatorname{height}(\mathfrak{a}) \quad \leq \quad \operatorname{kdim}(R)$$

(xi) Let $\mathfrak{q} \subseteq \mathfrak{q}$ are nested prime ideals of R, such that $\operatorname{height}(\mathfrak{q}) < \infty$ is finite. If we then regard $\mathfrak{q}/\mathfrak{p}$ as a prime ideal in the quotient ring $R/\mathfrak{p}$, we find the following estimate

$$\operatorname{height}\left(\mathfrak{q} \Big/ \mathfrak{p}\right) \quad \leq \quad \operatorname{height}(\mathfrak{q}) - \operatorname{height}(\mathfrak{p})$$

(xii) If now $\mathfrak{q}$ is a prime ideal of R, such that $1 \leq \operatorname{height}(\mathfrak{q}) < \infty$, then the height of $\mathfrak{q}$ is one step above the maximal height of any prime ideal lying directly under $\mathfrak{q}$. Formally put, that is

$$\operatorname{height}(\mathfrak{q}) \quad = \quad 1 + \max\{\, \operatorname{height}(\mathfrak{p}) \mid \mathfrak{p} \in \operatorname{Spec}(R) \text{ with } \mathfrak{p} \subset_* \mathfrak{q} \,\}$$

(xiii) Let $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be any ideal and $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$ be a prime ideal, such that $\mathfrak{a} \subseteq \mathfrak{p}$. Also let $a \in \operatorname{NZD}(R)$ be a non-zero-divisor of R that is contained in $a \in \mathfrak{a}$. Then $\mathfrak{p}/\mathfrak{a}$ is a prime ideal in the quotient ring $R/\mathfrak{a}$ and either $\operatorname{height}(\mathfrak{p}/\mathfrak{a}) = \operatorname{height}(\mathfrak{p}) = \infty$ or the height of this ideal is less, than the height of $\mathfrak{p}$. The latter formally is

$$\operatorname{height}\left(\mathfrak{p} \Big/ \mathfrak{a}\right) \quad < \quad \operatorname{height}(\mathfrak{p})$$

(8.70) Example:

(i) If $(F, +, \cdot)$ is a field, then $\operatorname{kdim}(F) = 0$, as (0) is the one and only chain of prime ideals, that is available in F, at all. This will be generalized in (iii) below.

(ii) If $(R,+,\cdot)$ is a PID, but not a field, then $\mathrm{kdim}(R) = 1$. This can be seen in the following way: Suppose $\mathcal{P} = (\mathfrak{p}_0,\ldots,\mathfrak{p}_n)$ is a CPI of R with $n = \mathrm{kdim}(R)$. Then $\mathcal{P}$ is maximal and hence $\mathfrak{p}_0 = 0$, as this is the one and only minimal prime ideal of R. Now $\mathfrak{p}_k = p_k R$ for some prime elements $p_k \in R$. As $\mathfrak{p}_{k-1} \subseteq \mathfrak{p}_k$ we have $p_k \mid p_{k-1}$. But as p_{k-1} is prime this would mean $p_k \approx p_{k-1}$ by (2.58.(vi)). This again would be $\mathfrak{p}_{k-1} = \mathfrak{p}_k$ such that $n \geq 2$ is ruled out. Hence the CPI is $(0, p_1 R)$ at most and hence $1 = n = \mathrm{kdim}(R)$.

(iii) Any commutative ring $(R,+,\cdot)$ has $\mathrm{kdim}(R) = 0$ if and only if all of its prime ideals already are maximal. That is we have the following equivalence

$$\mathrm{kdim}(R) \;=\; 0 \quad\Longleftrightarrow\quad \mathrm{Spec}(R) \;=\; \mathrm{Smax}(R)$$

This equivalence can be seen in the following way: If $\mathrm{kdim}(R) = 0$ and $\mathfrak{p}$ is any prime ideal of R, then $\mathcal{P} = (\mathfrak{p})$ is a CPI with $\ell(\mathcal{P}) = 0 = \mathrm{kdim}(R)$. In particular $\mathcal{P}$ is a maximal CPI and hence $\mathfrak{p}$ is a maximal ideal. Conversely, if $\mathrm{Spec}(R) = \mathrm{Smax}(R)$, then in any CPI $(\mathfrak{p}_0,\ldots,\mathfrak{p}_n)$ of R, the first ideal $\mathfrak{p}_0$ is prime and hence maximal. But therefore there can be no $\mathfrak{p}_1$, only $n = 0$ and this means $\mathrm{kdim}(R) = 0$. Nota In the light of (2.37.(e)) this means: R is artinian if and only if R is a noetherian ring, with $\mathrm{kdim}(R) = 0$.

(iv) Consider the polynomial $t^5 \in \mathbb{C}[t]$ and let $R := \mathbb{C}[t]/t^5\mathbb{C}[t]$ be the quotient ring. Then the element $a := t^2 + t^5\mathbb{C}[t] \in R$ is a zero-divisor, as $(t^3 + t^5\mathbb{C}[t])(t^2 + t^5\mathbb{C}[t]) = 0$. Now $\mathfrak{p} := (t + t^5\mathbb{C}[t])R$ is a prime ideal of R, containing $a \in \mathfrak{p}$. But $\mathfrak{p}$ is a minimal prime in R and hence $\mathrm{height}(\mathfrak{p}) = 0$. This example shows, that zero-divisors do not have to contribute to the height of prime ideals.

(v) Being noetherian and being finite-dimensional are not necessary for one and another: That is non-noetherian rings may have finite Krull-dimension and noetherian rings may have infinite Krull-dimension. Here comes a cunning example (found by Nagata) of a ring, that is noetherian, but has infinite Krull-dimension. We only give a sketch of the construction here, more details on why it works out can be found at (■) https://math.stackexchange.com/questions/1109732/noetherian-ring-with- infinite-krull-dimension-nagatas-example.

Pick up any field F and let $A := F[t_1, t_2, \ldots]$ be the polynomial ring in countably many variables. Recursively define the indices $m(0) := 0$ and for $k \geq 1$ also $m(k) := m(k-1) + k$. That is $m(1) = 1$, $m(2) = 3$, $m(3) = 6$ and so on. Then for any $1 \leq k \in \mathbb{N}$ we take the prime ideal

$$\mathfrak{p}_k \;:= \langle t_j \mid m(k-1) < j \leq m(k) \rangle_{\mathrm{i}} \quad \trianglelefteq_{\mathrm{i}} \quad A$$

That is $\mathfrak{p}_1 = t_1 A$, $\mathfrak{p}_2 = t_2 A + t_3 A$, $\mathfrak{p}_3 = t_4 A + t_5 A + t_6 A$ and so on. As any $R \setminus \mathfrak{p}_k$ is multiplicatively closed, we obtain a multiplicatively closed subset U of A by intersection

$$U \;:=\; \bigcap_{k \geq 1} (R \setminus \mathfrak{p}_k)$$

The evil ring now is $R := U^{-1}A$. Then any $\mathfrak{m}_k := U^{-1}\mathfrak{p}_k$ is a maximal ideal of R, in fact these are all the maximal ideals of R. And the height of $\mathfrak{m}_k$ is given to be

$$\mathrm{height}(\mathfrak{m}_k) \;=\; m(k) - m(k-1) \;=\; k$$

This means R contains maximal ideals of unbounded height and therefore cannot have a finite Krull-dimension. Yet it can be proved that R is noetherian, as all the localisations $R_{\mathfrak{m}}$ for $\mathfrak{m} \in \mathrm{Smax}(R)$ are noetherian. Recall that is suffices to check this for all $\mathfrak{m} = \mathfrak{m}_k$.

(8.71) Remark:
Let $(R, +, \cdot)$ be a finite-dimensional ring. Note that $n = \mathrm{kdim}(R)$ means, that for any CPI $(\mathfrak{p}_0, \ldots, \mathfrak{p}_m)$ of R we have $m \leq n$. Therefore the following two statements are easy to see:

(i) If $\mathcal{P} \in \mathrm{CPI}(R)$ is a chain of prime ideals of R, then there already is a chain $\mathcal{P}^* \in \mathrm{CPI}(R)$ of prime ideals, that is maximal and extends $\mathcal{P} \leq \mathcal{P}^*$.

(ii) If $\mathfrak{p} \subseteq \mathfrak{q} \in \mathrm{Spec}(R)$ are any two nested primes of R and $\mathcal{P} \in \mathrm{CPI}^{\mathfrak{q}}_{\mathfrak{p}}(R)$ is a chain of prime ideals of R, then there already is a chain $\mathcal{P}^* \in \mathrm{CPI}^{\mathfrak{q}}_{\mathfrak{p}}(R)$ that is saturated and extends $\mathcal{P} \leq \mathcal{P}^*$.

Prob If $\mathcal{P}$ is maximal itself, then we are done. Otherwise there is some $\mathcal{P}_1 \in \mathrm{CPI}(R)$ with $\mathcal{P} < \mathcal{P}_1$. In particular $\ell(\mathcal{P}) < \ell(\mathcal{P}_1) \leq \mathrm{kdim}(R)$. If $\mathcal{P}_1$ is maximal, we are done, otherwise we continue with $\mathcal{P}_1$ and pick up $\mathcal{P}_2$ with $\mathcal{P}_1 < \mathcal{P}_2$ and so on. This can be done at most $m \leq \mathrm{kdim}(R) - \ell(\mathcal{P})$ times, so with $\mathcal{P}_m$ we cannot continue. But this happens only if $\mathcal{P}_m$ is maximal and we have $\mathcal{P} \leq \mathcal{P}_m$ by construction. The reasoning for (ii) is literally the same if you replace $\mathrm{CPI}(R)$ by $\mathrm{CPI}^{\mathfrak{q}}_{\mathfrak{p}}(R)$ and *maximal* with *saturated*.

(8.72) Lemma: (viz. 1240)

(i) *Lying-over Theorem*: If $S : R$ is an integral ring extension and $\mathfrak{q}_0 \subset \ldots \subset \mathfrak{q}_r$ is a CPI of S, then the pull-back $\mathfrak{q}_0 \cap R \subset \ldots \subset \mathfrak{q}_r \cap R$ is a CPI of R, as well.

(ii) *Going-up Theorem*: If $S : R$ is an integral ring extension, $\mathfrak{p}_0 \subset \ldots \subset \mathfrak{p}_r$ is a CPI of R and $\mathfrak{q}_0 \in \mathrm{Spec}(S)$ is a prime ideal in S such that $\mathfrak{q}_0 \cap R = \mathfrak{p}_0$, then there is $\mathfrak{q}_0 \subset \ldots \subset \mathfrak{q}_r$ a CPI of S such that we get $\mathfrak{q}_i \cap R = \mathfrak{p}_i$ for any $i \in 1 \ldots r$.

(iii) *Going-down Theorem*: Let $S : R$ be an integral ring extension, such that R is a normal domain and S is torsion-free, as an R module. Now consider $\mathfrak{p}_0 \subset \ldots \subset \mathfrak{p}_r$ a CPI of R and $\mathfrak{q}_r \in \mathrm{Spec}(S)$ a prime ideal in S such that $\mathfrak{q}_r \cap R = \mathfrak{p}_r$, then there is $\mathfrak{q}_0 \subset \ldots \subset \mathfrak{q}_r$ a CPI of S such that we get $\mathfrak{q}_i \cap R = \mathfrak{p}_i$ for any $i \in 1 \ldots r$.

(8.73) Corollary: (viz. 1244)

(i) Let $S : R$ be an integral ring extension, then R and S share the same Krull dimension, formally

$$\mathrm{kdim}(R) \;=\; \mathrm{kdim}(S)$$

(ii) If $S : R$ is an integral ring extension and $\mathfrak{u} \trianglelefteq_{\mathfrak{i}} S$ is any ideal of S, then we also find the following identity of Krull-dimensions

$$\mathrm{kdim}\left(S \big/ \mathfrak{u}\right) \;=\; \mathrm{kdim}\left(R \big/ \mathfrak{u} \cap R\right)$$

(iii) If $S : R$ is an integral ring extension and $\mathfrak{u} \trianglelefteq_{\mathrm{i}} S$ is any ideal of S, then the height of $\mathfrak{u} \cap R$ cannot exceed the height of $\mathfrak{u}$ that is we have the inequality

$$\operatorname{height}\big(\mathfrak{u} \cap R\big) \;\leq\; \operatorname{height}\big(\mathfrak{u}\big)$$

(iv) Let $S : R$ be an integral ring extension, such that R is a normal domain and S is torsion-free, as an R-module. If now $\mathfrak{q} \trianglelefteq_{\mathrm{i}} S$ is any prime ideal of S, then we even get

$$\operatorname{height}\big(\mathfrak{q} \cap R\big) \;=\; \operatorname{height}\big(\mathfrak{q}\big)$$

(8.74) Definition:

(i) A commutative ring $(R, +, \cdot)$ is said to be **holodimensional** if $\operatorname{kdim}(R) < \infty$ it has finite Krull-dimension and for any chain of prime ideals $\mathcal{P} \in \mathrm{CPI}(R)$ of R we get the equivalence

$$\mathcal{P} \text{ is maximal} \iff \ell(\mathcal{P}) = \operatorname{kdim}(R)$$

(ii) A commutative ring $(R, +, \cdot)$ is said to be **equidimensional** if $\operatorname{kdim}(R) < \infty$ it has finite Krull-dimension and any two maximal ideals $\mathfrak{m}, \mathfrak{n} \in \operatorname{Smax}(R)$ have the same height, that is

$$\mathfrak{m}, \mathfrak{n} \in \operatorname{Smax}(R) \implies \operatorname{height}(\mathfrak{m}) = \operatorname{height}(\mathfrak{n})$$

(iii) A commutative ring $(R, +, \cdot)$ is said to be **catenary** (this word is derived from the Latin word *catena* for *chain*), iff for any two prime ideals $\mathfrak{p}, \mathfrak{q} \in \operatorname{Spec}(R)$ with $\mathfrak{p} \subset \mathfrak{q}$ we have the properties:

(1) The prime ideals $\mathfrak{p}$ and $\mathfrak{q}$ can be connected by a maximal CPI, that is: There is a saturated chain of prime ideals $\mathcal{P} \in \mathrm{CPI}_{\mathfrak{p}}^{\mathfrak{q}}(R)$.

(2) Any two saturated chains of prime ideals $\mathcal{P}, \mathcal{Q} \in \mathrm{CPI}_{\mathfrak{p}}^{\mathfrak{q}}(R)$ have the same length: $\ell(\mathcal{P}) = \ell(\mathcal{Q})$.

(iv) A commutative ring $(R, +, \cdot)$ is said to be **universally catenary**, iff for any commutative R-algebra A we get the implication: If A is finitely generated as an R-algebra, then A also is catenary.

(8.75) Proposition: (viz. 1272)

(i) If $(R, +, \cdot)$ is a holodimensional ring, then it already is equidimensional and catenary and for any prime ideal $\mathfrak{p} \in \operatorname{Spec}(R)$ we have the identity

$$\operatorname{kdim}\left(R \big/ \mathfrak{p}\right) + \operatorname{height}(\mathfrak{p}) \;=\; \operatorname{kdim}(R)$$

(ii) Let $(R, +, \cdot)$ be a commutative ring and $\mathfrak{p} \subseteq \mathfrak{q}$ be nested prime ideals of R, such that $R/\mathfrak{p}$ is holodimensional. Then any saturated chain $\mathcal{P} \in \mathrm{CPI}_{\mathfrak{p}}^{\mathfrak{q}}(R)$, ranging from $\mathfrak{p}$ to $\mathfrak{q}$, is of length

$$\ell(\mathcal{P}) \;=\; \operatorname{kdim}\left(R \big/ \mathfrak{p}\right) - \operatorname{kdim}\left(R \big/ \mathfrak{q}\right) \;=\; \operatorname{height}\left(\mathfrak{q} \big/ \mathfrak{p}\right) \;=\; \operatorname{height}(\mathfrak{q}) - \operatorname{height}(\mathfrak{p})$$

(iii) If $(R,+,\cdot)$ is a holodimensional ring and $\mathfrak{p} \in \operatorname{Spec}(R)$ is any prime ideal of R, then the quotient ring $R/\mathfrak{p}$ also is a holodimensional ring of Krull-dimension

$$\operatorname{kdim}\left(R \Big/ \mathfrak{p}\right) \;=\; \operatorname{kdim}(R) - \operatorname{height}(\mathfrak{p})$$

(iv) If $(R,+,\cdot)$ is a noetherian ring (actually we only need $\operatorname{height}(\mathfrak{p}) < \infty$ for any prime ideal $\mathfrak{p} \trianglelefteq_{\mathrm{i}} R$), then the following statements (a) and (b) are equivalent. And in this case R is catenary.

(a) For any prime ideals $\mathfrak{p}, \mathfrak{q} \in \operatorname{Spec}(R)$ such that $\mathfrak{p} \subset_* \mathfrak{q}$ we have $\operatorname{height}(\mathfrak{q}) = \operatorname{height}(\mathfrak{p}) + 1$.

(b) For any prime ideals $\mathfrak{p}, \mathfrak{q} \in \operatorname{Spec}(R)$ such that $\mathfrak{p} \subseteq \mathfrak{q}$ we regard $\mathfrak{q}/\mathfrak{p}$ as a prime ideal in the quotient ring $R/\mathfrak{p}$. And thereby we have the identity

$$\operatorname{height}\left(\mathfrak{q} \Big/ \mathfrak{p}\right) \;=\; \operatorname{height}(\mathfrak{q}) - \operatorname{height}(\mathfrak{p})$$

Nota It might come as a surprise, but the converse is untrue: Even if R is catenary properties (a) and (b) need *not* be true. We will present a counterexample of this in (8.82.(4)).

(v) If $(R,+,\cdot)$ is a holodimensional ring and $\mathfrak{p} \in \operatorname{Spec}(R)$ is any prime ideal of R, then the localisation $R_{\mathfrak{p}}$ also is a holodimensional local ring of Krull-dimension

$$\operatorname{kdim}\big(R_{\mathfrak{p}}\big) \;=\; \operatorname{kdim}(R) - \operatorname{kdim}\left(R \Big/ \mathfrak{p}\right)$$

(vi) If $(R,+,\cdot)$ is an integral domain, that is equidimensional and catenary, then R is holodimensional.

Noetherian Normalisation and Krull Dimension

Let us revisit the noetherian normalisation theorem (8.52) in the light of the notions of Krull's dimension. It will turn out, that finitely generated algebras A over fields are very well-behaved. There are still a lot of powerful theorems for general noetherian rings R, but those of algebras are even better:

(8.76) Proposition: (viz. 1276)

(i) Let $(E,+,\cdot)$ be a field and A a finitely generated E-algebra, such that A also is an integral domain. Then the length of any maximal CPI equals $\operatorname{trdeg}(A:E)$. In particular A is holodimensional and

$$\operatorname{kdim}(A) \;=\; \operatorname{trdeg}(A:E) \;<\; \infty$$

(ii) Let $(E,+,\cdot)$ be a field and $A \neq 0$ be any finitely generated E-algebra. Then A only has finitely many minimal prime ideals and for the the Krull-dimension of A we find the identity

$$\operatorname{kdim}(A) \;=\; \max\left\{ \operatorname{kdim}\left(A \Big/ \mathfrak{n}\right) \;\middle|\; \mathfrak{n} \in \operatorname{Smin}(A) \right\} \;<\; \infty$$

(iii) Any field $(E,+,\cdot)$ is universally catenary, that is any finitely generated E-algebra A is catenary. In fact we even get: For any prime ideal $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} A$, the quotient $A/\mathfrak{p}$ is holodimensional and if $\mathfrak{q} \trianglelefteq_{\mathfrak{i}} A$ is another prime ideal of A, with $\mathfrak{p} \subseteq \mathfrak{q}$, then any saturated CPI $\mathcal{P} \in \mathrm{CPI}_{\mathfrak{p}}^{\mathfrak{q}}(A)$ has the same length

$$\ell(\mathcal{P}) \;=\; \mathrm{kdim}\left(A \Big/ \mathfrak{p}\right) - \mathrm{kdim}\left(A \Big/ \mathfrak{q}\right) \;=\; \mathrm{height}(\mathfrak{q}) - \mathrm{height}(\mathfrak{p})$$

(iv) Let $(E,+,\cdot)$ be a field and $A \neq 0$ be a finitely generated E-algebra. Also consider a chain $\mathfrak{a}_1 \subseteq \mathfrak{a}_2 \subseteq \ldots \subseteq \mathfrak{a}_r \trianglelefteq_{\mathfrak{i}} A$ of proper ideals in A, that is $\mathfrak{a}_r \neq A$, of length $r \in \mathbb{N}$. By (8.52) there are algebraically independent elements $z_1,\ldots,z_n \in A$ and numbers $0 \leq k(1) \leq k(2) \leq \cdots \leq k(r) \leq n$ such that letting $P := E[z_1,\ldots,z_n]$ for any $i \in 1\ldots r$ we have

$$\mathfrak{a}_i \cap P \;=\; z_1P + \cdots + z_{k(i)}P$$

Then (1) A has Krull-dimension n and (2) if A is an integral domain then any of the ideals $\mathfrak{a}_i$ has height $k(i)$. In consequence the numbers n and $k(i)$ are uniquely determined by A resp. the ideals $\mathfrak{a}_i$ independent of the specific normalisation

$$\begin{aligned} \mathrm{kdim}(A) &= n \\ \mathrm{height}(\mathfrak{a}_i) &= k(i) \end{aligned}$$

(8.77) Remark:

(i) If $(E,+,\cdot)$ is a field and $n \in \mathbb{N}$ then the polynomial ring in n variables $E[t_1,\ldots,t_n]$ satisfies the properties required in (8.76.(i)) above. In particular it is an integral domain. And as the variables $\{\, t_1,\ldots,t_n \,\}$ are a transcendence basis of $E[t_1,\ldots,t_n] : E$ we conclude, that $E[t_1,\ldots,t_n]$ is holodimensional of Krull-dimension

$$\mathrm{kdim}\big(E[t_1,\ldots,t_n]\big) \;=\; n$$

(ii) Fix any $k \in 0\ldots n$ then the ideal $\langle t_1,\ldots,t_k\rangle_{\mathfrak{i}}$ of the polynomial ring $E[t_1,\ldots,t_n]$ clearly is a prime ideal of height k. In the next section this property will be formulated, as "$(t_1,\ldots,t_n)$ is a regular sequence of $E[t_1,\ldots,t_n]$".

$$\mathrm{height}\big(\langle t_1,\ldots,t_k\rangle_{\mathfrak{i}}\big) \;=\; k$$

Prob Clearly $E[t_1,\ldots,t_n]/\langle t_1,\ldots,t_k\rangle_{\mathfrak{i}}$ is isomorphic to $E[t_{k+1},\ldots,t_n]$ which is a polynomial ring in $n-k$ variables. And as $E[t_1,\ldots,t_n]$ is holodimensional, we may compute the height of $\langle t_1,\ldots,t_k\rangle_{\mathfrak{i}}$ using (i) above and the formula in (8.75.(i))

$$\mathrm{height}\big(\langle t_1,\ldots,t_k\rangle_{\mathfrak{i}}\big) \;=\; \mathrm{kdim}\big(E[t_1,\ldots,t_n]\big) - \mathrm{kdim}\left(E[t_1,\ldots,t_n] \Big/ \langle t_1,\ldots,t_k\rangle_{\mathfrak{i}}\right) \;=\; k$$

(8.78) Corollary: (viz. 1280)
Let $(E,+,\cdot)$ be a field and $A \neq 0$ a finitely generated, commutative E-algebra Also let $\mathfrak{p} \in \operatorname{Spec}(A)$ be a prime ideal. Then we obtain the following properties

(i) Let $E_\mathfrak{p} := A_\mathfrak{p}/\mathfrak{p}A_\mathfrak{p}$ denote the quotient field of the localisation $A_\mathfrak{p}$. This is an E-algebra under the scalar multiplication $a(f/u + \mathfrak{p}A_\mathfrak{p}) := (af)/u\mathfrak{p}A_\mathfrak{p}$. And thereby we get

$$\operatorname{trdeg}\big(E_\mathfrak{p} : E\big) \;=\; \operatorname{kdim}\Big(A \Big/ \mathfrak{p}\Big)$$

(ii) For a CPI $\mathcal{P} = (\mathfrak{p}_0,\ldots,\mathfrak{p}_r)$ of A let us denote $\mathfrak{p} \in \mathcal{P}$ if and only if $\mathfrak{p} = \mathfrak{p}_i$ for some $i \in 0\ldots r$. Then we obtain the following identities

$$\begin{aligned}\operatorname{kdim}\Big(A \Big/ \mathfrak{p}\Big) + \operatorname{height}(\mathfrak{p}) &= \sup\left\{ \ell(\mathcal{P}) \;\middle|\; \begin{array}{l}\mathcal{P} \in \operatorname{CPI}(A)\\ \text{with } \mathfrak{p} \in \mathcal{P}\end{array} \right\}\\ &= \max\left\{ \operatorname{kdim}\Big(A \Big/ \mathfrak{p}_*\Big) \;\middle|\; \begin{array}{l}\mathfrak{p}_* \in \operatorname{Smin}(A)\\ \text{with } \mathfrak{p}_* \subseteq \mathfrak{p}\end{array} \right\}\end{aligned}$$

(iii) By (8.52) there are algebraically independent elements $z_1,\ldots,z_n \in A$ and $k \in 0\ldots n$ such that $A : P$ is finite, where $P := E[z_1,\ldots,z_n]$ and we also get $\mathfrak{p} \cap P = z_1P + \cdots + z_kP$. From this we get a *Noetherian normalisation* of $A/\mathfrak{p}$ in the following way: For any $x \in A$ let us abbreviate the residue element $\overline{x} := x + \mathfrak{p} \in A/\mathfrak{p}$, then we get

(1) $\{\,\overline{z}_{k+1},\ldots,\overline{z}_n\,\} \subseteq A/\mathfrak{p}$ is algebraically independent
(2) $A/\mathfrak{p} : \overline{P}$ is a finite ring-extension, where $\overline{P} := E[\overline{z}_{k+1},\ldots,\overline{z}_n]$
(3) $\operatorname{kdim}(A/\mathfrak{p}) = n - k$
(4) We find an isomorphism of E-algebras, that can be explicitly given to be the following map

$$P \Big/ \mathfrak{p} \cap P \;\xrightarrow{\sim}\; \overline{P} \;:\; f(z_1,\ldots,z_n) + \mathfrak{p} \cap P \mapsto f(0,\ldots,0,\overline{z}_{k+1},\ldots,\overline{z}_n)$$

(5) If $\mathfrak{p} \subseteq \mathfrak{a}_1 \subseteq \ldots \subseteq \mathfrak{a}_r \neq A$ is a chain of proper ideals of A, containing $\mathfrak{p}$ and we are given the ascending chain of numbers $0 \leq k(1) \leq \cdots \leq k(r) \leq n$s, such that $\mathfrak{a}_i \cap P = z_1P + \cdots + z_{k(i)}P$ for any $i \in 1\ldots r$, then we find that $k \leq k(1)$ and

$$\mathfrak{a}_i \Big/ \mathfrak{p} \cap \overline{P} \;=\; \overline{z}_{k+1}\overline{P} + \cdots + \overline{z}_{k(i)}\overline{P}$$

(8.79) Corollary: (viz. 1282)
Let $(E,+,\cdot)$ be a field and A be any E-algebra (not necessarily finitely generated). Let us agree to call the maximal number of algebraically independent elements inside A the *transcendent freedom* of $A : E$

$$\operatorname{tfree}(A : E) \;:=\; \max\{\,\#U \mid U \subseteq A,\, U \text{ algebraically independent}\,\}$$

In particular: If A contains an infinite set $U \subseteq A$ that is algebraically independent, then $\operatorname{tfree}(A) = \infty$. And if $\operatorname{tfree}(A : E) = n$ is finite, then any algebraically independent set $U \subseteq A$ contains no more than n elements. Using this notion we obtain the following statements:

(i) If A is an integral domain, then $\operatorname{tfree}(A : E) = \operatorname{trdeg}(A : E)$.

(ii) If $\mathfrak{q} \in \operatorname{Spec}(A)$ is a prime ideal, then $A/\mathfrak{q}$ becomes an E-algebra under the scalar multiplication $a(x+\mathfrak{q}) := ax + \mathfrak{q}$. And thereby we find the estimate

$$\operatorname{tfree}\left(A \Big/ \mathfrak{q} : E\right) \quad \leq \quad \operatorname{tfree}(A : E)$$

(iii) If A is an integral domain and a finitely generated E-algebra, then we have $\operatorname{kdim}(A) = \operatorname{trdeg}(A : E)$. For a general E-algebra, we still retain the inequality

$$\operatorname{kdim}(A) \quad \leq \quad \operatorname{tfree}(A : E)$$

Nota This inequality may be strict: Consider $F = E(t_1, \ldots, t_n) = \textsc{quot}\big(E[t_1, \ldots, t_n]\big)$ the field of rational functions in n variables. Then $\operatorname{kdim}(F) = 0$, as F is a field. But $\operatorname{trdeg}(F : E) = n$, as the variables $\{ t_1, \ldots, t_n \}$ are algebraically independent.

(iv) If A is a finitely generated E-algebra, that also is an integral domain and $P \leq_{\mathsf{a}} A$ is an E-subalgebra of A, then we get [whether P is finitely generated or not]

$$\operatorname{kdim}(P) \quad \leq \quad \operatorname{kdim}(A)$$

Krull's Theorems

We finally reached the core of dimension theory: Krull's theorems study the connection between the height and the number of generators of an ideal $\mathfrak{a}$ in a noetherian ring R. If we think of an affine variety $X \subseteq E^n$, then $R = E[t_1, \ldots, t_n]$ is the polynomial ring and $\mathfrak{a} = \mathbb{I}(X)$ is the vanishing ideal of X. Then $\operatorname{height}(\mathfrak{a})$ is the dimension of X and $\operatorname{rank}(\mathfrak{a})$ is the minimal number of equations used to define X. It turns out that if we use k equations $f_1, \ldots, f_k \in R$ to define X, then the dimension of X is $n - k$ or more. Without equations we start at n and any additional equation can reduce the dimension by 1, at most. This is the fundamental interpretation behind these theorems:

(8.80) Theorem: (viz. 1283)

(i) *Krull's principal Ideal Theorem:* Let $(R, +, \cdot)$ be a noetherian ring, $a \in R$ an element and let $\mathfrak{p} \in \operatorname{Spec}(R)$ be a prime ideal, that is minimal over $aR \trianglelefteq_{\mathsf{i}} R$. Then $\mathfrak{p}$ has height 1 or less. Formally

$$\mathfrak{p} \in \mathbb{V}(aR)_* \quad \Longrightarrow \quad \operatorname{height}(\mathfrak{p}) \leq 1$$

(ii) *Krull's Height Theorem:* Let $(R, +, \cdot)$ be a noetherian ring and fix $n \in \mathbb{N}$ with $n \geq 1$. If now $\mathfrak{p} \in \operatorname{Spec}(R)$ is a prime ideal, then the following two statements are equivalent

(a) $\operatorname{height}(\mathfrak{p}) \leq n$

(b) There are some $a_1, \ldots, a_n \in \mathfrak{p}$ such that $\mathfrak{p}$ is a minimal prime ideal $\mathfrak{p} \in \mathbb{V}(\mathfrak{a})_*$ over the ideal $\mathfrak{a} := \langle a_1, \ldots, a_n \rangle_{\mathsf{i}}$ generated by these elements.

Nota If $\mathfrak{p} = \mathfrak{a} = \langle a_1, \ldots, a_n \rangle_{\mathsf{i}}$ then $\mathfrak{p}$ is the only minimal prime over $\mathfrak{a}$, in particular $\operatorname{height}(\mathfrak{p}) \leq n$. That means that any (prime) ideal in a noetherian ring has finite height. However there is no upper bound to the number of generators required and hence to the height of prime ideals, such that R may have $\operatorname{kdim}(R) = \infty$, never the less.

(iii) Let $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be a proper ideal $\mathfrak{a} \neq R$ in a noetherian ring $(R,+,\cdot)$. Recall that the rank of $\mathfrak{a}$ as an R-module is $\operatorname{rank}(\mathfrak{a}) = \min\{\, n \in \mathbb{N} \mid \exists\, a_1,\ldots,a_n \in R : \mathfrak{a} = \langle a_1,\ldots,a_n\rangle_{\mathrm{i}} \,\}$ the minimal number of generators of $\mathfrak{a}$. And it always takes at least n elements, to build up an ideal of height n

$$\operatorname{height}(\mathfrak{a}) \;\leq\; \operatorname{rank}(\mathfrak{a})$$

(iv) If $(R,+,\cdot)$ is a noetherian ring and $(\mathfrak{p}_0,\ldots,\mathfrak{p}_r)$ is a CPI of R where $r \geq 1$ and $a \in \mathfrak{p}_r$ is any element, then there is another CPI of R, of the form $(\mathfrak{p}_0,\widetilde{\mathfrak{p}}_1,\ldots,\widetilde{\mathfrak{p}}_{r-1},\mathfrak{p}_r)$, such that we get $a \in \widetilde{\mathfrak{p}}_1$.

(v) Let $(R,+,\cdot)$ be a noetherian ring, $\mathfrak{a}$, $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ be ideals of R, such that $\mathfrak{a} \subseteq \mathfrak{b}$ and fix m, $n \in \mathbb{N}$ such that $0 \leq m \leq n$. Also consider $a_1,\ldots,a_m \in R$ such that $\mathfrak{a} = \langle a_1,\ldots,a_m\rangle_{\mathrm{i}}$ and suppose $\operatorname{height}(\mathfrak{a}) = m$ and $\operatorname{height}(\mathfrak{b}) \geq n$. Then we can append elements $a_{m+1},\ldots,a_n \in \mathfrak{b}$ with the following property: Let us denote $\mathfrak{a}_k := \langle a_1,\ldots,a_k\rangle_{\mathrm{i}}$, in particular $\mathfrak{a}_m = \mathfrak{a}$. Then for any $k \in m\ldots n$ we get $\operatorname{height}(\mathfrak{a}_k) = k$. In fact we even get a much stronger property: If $\mathfrak{p}_k \in \operatorname{Spec}(R)$ is any prime ideal, minimal over $\mathfrak{a}_k$ then we have

$$\operatorname{height}(\mathfrak{p}_k) \;=\; k$$

(vi) Let $(\mathfrak{p}_0,\ldots,\mathfrak{p}_r)$ be a CPI in a noetherian ring $(R,+,\cdot)$ such that $r = \operatorname{height}(\mathfrak{p}_r)$. Then there are some elements $a_1,\ldots,a_r \in R$ such that for any $k \in 0\ldots r$ the ideal $\mathfrak{a}_k := \langle a_1,\ldots,a_k\rangle_{\mathrm{i}}$ has the following two properties

(1) $\operatorname{height}(\mathfrak{a}_k) = k$

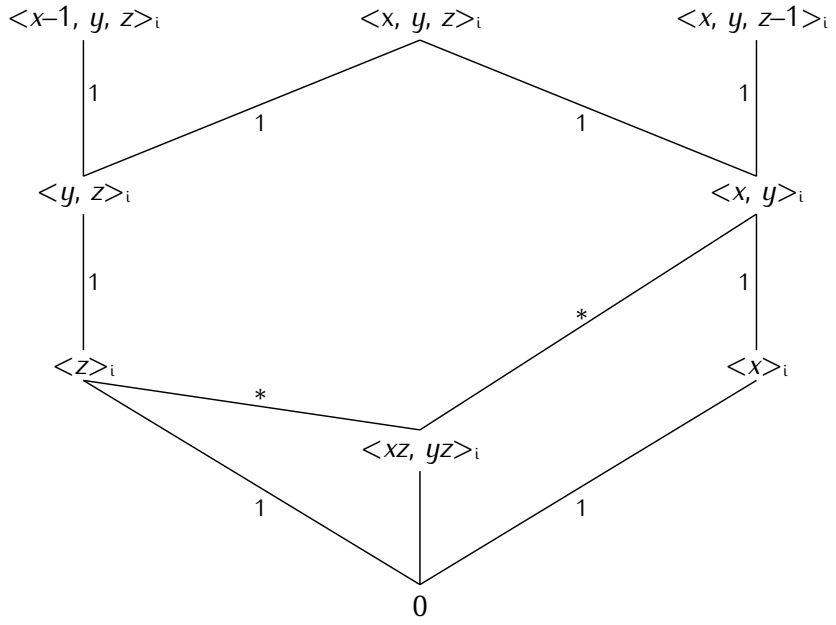
(2) $\mathfrak{p}_k$ is minimal over $\mathfrak{a}_k$

(vii) Let $(R,+,\cdot)$ is a noetherian ring and $a \in \operatorname{NZD}(R)$ be a non-zero-divisor that is contained in $a \in \mathfrak{p} \in \operatorname{Spec}(R)$. Then $\mathfrak{p}/aR$ is a prime ideal in the quotient ring R/aR and the height of this ideal is one less, than the height of $\mathfrak{p}$. Formally that is

$$\operatorname{height}\left(\mathfrak{p} \Big/ {}_{aR}\right) \;=\; \operatorname{height}(\mathfrak{p}) - 1$$

(8.81) Remark:
Let us analyse what $\operatorname{height}(\mathfrak{p}) = n$ means for a prime ideal $\mathfrak{p} \in \operatorname{Spec}(R)$ in a noetherian ring R. Due to the equivalence in Krull's height theorem we can break it down into the following two properties

(1) There are some $a_1,\ldots,a_n \in \mathfrak{p}$ such that $\mathfrak{p}$ is a minimal prime ideal $\mathfrak{p} \in \mathbb{V}(\mathfrak{a})_*$ over the ideal $\mathfrak{a} := \langle a_1,\ldots,a_n\rangle_{\mathrm{i}}$ generated by these elements.



(2) For any $b_1,\ldots,b_m \in \mathfrak{p}$ with $0 \leq m < n$ there is another prime ideal $\mathfrak{p}' \in \operatorname{Spec}(R)$ such that $\mathfrak{b} \subseteq \mathfrak{p}' \subset \mathfrak{p}$, where $\mathfrak{b} := \langle b_1,\ldots,b_m\rangle_{\mathrm{i}}$ denotes the ideal generated by these elements.

This is readily apparent, as (2) is just the negation of (b) in (8.80.(ii)). The converse is also true: If $\mathfrak{p} \in \operatorname{Spec}(R)$ satisfies (1) and (2), then $\operatorname{height}(\mathfrak{p}) = n$. In fact we have to check (2) for $m = n-1$ only, as this property then is inherited by all $0 \leq m < n$.

(8.82) Example: (viz. 1288)
If A is not an integral domain, weird things may happen: Consider the polynomial ring in 3 variables over a field $R = E[x,y,z]$. Then we take a look at the E-algebra

$$A \;:=\; E[x,y,z] \Big/ \mathfrak{a} \quad \text{where} \quad \mathfrak{a} \;:=\; \langle xz, yz \rangle_{\mathrm{i}}$$

Geometrically speaking A is corresponds to the union of the xy-plane $\langle z \rangle_{\mathrm{i}}$ and the z-axis $\langle x,y \rangle_{\mathrm{i}}$. The following diagram illustrates the structure some ideals in R. The numbers stand for the difference in height and the asterisks indicate that the upper ideal is minimal over the lower one. For any polynomial $f \in E[x,y,z]$ let us abbreviate $\overline{f} := f + \mathfrak{a} \in A$, then A has the following properties

(1) Both zR and $xR + yR$ are prime ideals, that are minimal over $\mathfrak{a}$. That means, that an ideal $\mathfrak{a}$ may have minimal primes of different height on top of it.

(2) $\overline{z}A \subset \overline{y}A + \overline{z}A \subset \overline{x}A + \overline{y}A + \overline{z}A$ is a chain of prime ideals of A and hence $\operatorname{kdim}(A) = 2$. This shows, that not every element contained in $\mathfrak{a}$ reduces the dimension of A, by 1.

(3) The set $\{\, \overline{x}, \overline{y} \,\} \subseteq A$ is something like a transcendence basis: It is algebraically independent and $A : P$ is an algebraic extension, for $P := E[\overline{x}, \overline{y}]$. However $A : P$ is not a finite extension and as A is not an integral domain algebraic dependence is not a dependence relation.

(4) As E is a field and A is an E-algebra generated by finitely many elements $\{\, \overline{x}, \overline{y}, \overline{z} \,\}$, A is catenary by (8.76.(iii)). However the ideals $\overline{\mathfrak{m}} := \langle x,y,z \rangle_{\mathrm{i}} / \mathfrak{a}$ and $\overline{\mathfrak{q}} = \langle x,y \rangle_{\mathrm{i}} / \mathfrak{a}$ satisfy

$$\operatorname{height}\left(\overline{\mathfrak{m}} \Big/ \overline{\mathfrak{q}} \right) \;=\; 1 \;<\; 2 - 0 \;=\; \operatorname{height}(\overline{\mathfrak{m}}) - \operatorname{height}(\overline{\mathfrak{q}})$$

(8.83) Example: (viz. 1289)
It can happen, that the height of a prime ideal is strictly less, than the minimal number of generators of a prime ideal: Consider any field E and regard polynomial ring in three resp. in one variable: $E[x,y,z]$ and $E[t]$. Then we regard the following homomorphism of E-algebras

$$\pi \;:\; E[x,y,z] \;\to\; E[t] \;:\; f \mapsto f(t^3,t^4,t^5)$$

(1) Then $\mathfrak{p} := \mathrm{kn}(\pi)$ is a prime ideal, strictly contained in $\mathfrak{m} = \langle x,y,z\rangle_{\mathrm{i}}$ and therefore $\mathrm{height}(\mathfrak{p}) = 2$.

(2) Also $\mathfrak{p} = \langle f_1,f_2,f_3\rangle_{\mathrm{i}}$ is generated by 3 elements, namely $f_1 = xz - y^2$, $f_2 = yz - x^3$ and $f_3 = x^2y - z^2$. Yet $\mathfrak{p}$ *cannot* be generated by 2 (or fewer) elements.

(8.84) Proposition: (viz. 1293)
Let $(R,+,\cdot)$ be a notherian ring and $\mathfrak{p} \subset \mathfrak{q}$ be two nested prime ideals of R. Then there are either no or infinitely many prime ideals $\mathfrak{p}'$ in between. That is the following set either is empty or infinite

$$\#\left\{\, \mathfrak{p}' \in \mathrm{Spec}(R) \mid \mathfrak{p} \subset \mathfrak{p}' \subset \mathfrak{q} \,\right\} \;\in\; \{\,0,\infty\,\}$$

And thereby a noetherian ring with only finitely many prime ideals either is a field or one-dimensional

$$\#\mathrm{Spec}(R) < \infty \quad\Longrightarrow\quad \mathrm{kdim}(R) \leq 1$$

(8.85) Theorem: (viz. 1291)

(i) Let $(R,+,\cdot)$ be a commutative ring and $\mathfrak{u} \in R[t]$ be a prime ideal in the polynomial ring over R. Let $\mathfrak{p} := \mathfrak{u} \cap R$, which is a prime ideal in R. Then the following two statements are equivalent

 (a) $\mathfrak{u} = \mathfrak{p}[t]$

 (b) There is a prime ideal $\mathfrak{v} \in R[t]$ that also lies over $\mathfrak{p}$ in R but lies strictly over $\mathfrak{u}$ in $R[t]$. That is $\mathfrak{v}$ satisfies the properties: $\mathfrak{u} \subset \mathfrak{v}$ and $\mathfrak{u} \cap R = \mathfrak{v} \cap R$.

(ii) Let $(R,+,\cdot)$ be a commutative ring, $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be any ideal and $\mathfrak{p} \in \mathrm{Spec}(R)$ be a prime ideal, such that $\mathfrak{a} \subseteq \mathfrak{p}$. Then we find the equivalence of the following two statements

 (a) $\mathfrak{p}$ is a minimal prime ideal over $\mathfrak{a}$

 (b) $\mathfrak{p}[t]$ is a minimal prime ideal over $\mathfrak{a}[t]$

(iii) Let $(R,+,\cdot)$ be a noetherian ring and $\mathfrak{p} \in \mathrm{Spec}(R)$ be a prime ideal. Then the height of $\mathfrak{p}$ in R equals the height of $\mathfrak{p}[t]$ in $R[t]$, formally that is

$$\mathrm{height}\big(\mathfrak{p}\big) \;=\; \mathrm{height}\big(\mathfrak{p}[t]\big)$$

(iv) If $(R,+,\cdot)$ is any commutative ring of Krull-dimension $n := \mathrm{kdim}(R)$. Then the Krull-dimension of the polynomial ring $R[t]$ has the following bounds

$$n+1 \;\leq\; \mathrm{kdim}\big(R[t]\big) \;\leq\; 2n+1$$

Nota these are not only theoretical bounds: In fact it can be proved, that any value in between is assumed by some ring. (■) Refer to P. Jaffard *Théorie de la dimension dans les anneaux des polynomes*. Memorial Sci. Math. 146 (1960).

(v) If $(R, +, \cdot)$ is a noetherian ring and $n \in \mathbb{N}$, then the Krull-dimension of the polynomial ring in n variables over R is given to be

$$\operatorname{kdim}\big(R[t_1, \ldots, t_n]\big) \;=\; \operatorname{kdim}(R) + n$$

8.8 Spectrum of a Ring

We have come a long way and have seen, that prime ideals are an extremely helpful tool, all around in algebra. They can be thought of as the proper generalisation of prime numbers in the integers and prime (mostly called irreducible) polynomials in $E[t]$. The common ground is, that they can be used to decompose more complex structures into parts, that are easier to control. For example recall the Lasker-Noether theorem (2.101), which is a generalisation of prime decomposition or Noetherian filtrations (5.14) that provide a way of dealing with a module, one step at a time.
But this is not the end of the story. Prime ideals are a strange looking glass through which we can study the structure af a ring. For example prime avoidance (2.14.(iii)) is a consequence of the prime property. And if F is an algebraically closed field, then $\mathrm{Smax}(F[t]) = \{\, (t-x)F[t] \mid x \in F \,\}$ - that is F itself corresponds to a special subset of the prime spectrum of $F[t]$. For a general field, the maximal spectrum of $F[t]$ will have additional points, that do not correspond to elements of F.
It is tempting to study the structure of the spectrum of a ring in order to learn something about the ring itself. This allows to introduce topology to the problem, but it also takes some time to get accustomed to the strange, distorted images, this looking glass provides.

Let us recollect, what we know so far: In (2.16) we have introduced the concept of the set of all prime ideals containing another ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$, for a commutative ring $(R,+,\cdot)$. This concept has a twin sister: The intersection of a set pf prime ideals, which is another ideal of R

$$\begin{aligned}
\mathbb{V} \;:\; \mathrm{Ideal}(R) \;&\to\; \mathcal{P}\big(\mathrm{Spec}(R)\big) \;:\; \mathfrak{a} \;\mapsto\; \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p} \,\} \\
\mathbb{I} \;:\; \mathcal{P}\big(\mathrm{Spec}(R)\big) \;&\to\; \mathrm{Ideal}(R) \;:\; \mathcal{P} \;\mapsto\; \begin{cases} \bigcap \mathcal{P} \text{ if } \mathcal{P} \neq \emptyset \\ R \text{ if } \mathcal{P} = \emptyset \end{cases}
\end{aligned}$$

It is clear, that $\mathbb{V}(0) = \mathrm{Spec}(R)$ and $\mathbb{V}(R) = \emptyset$. Also we have seen in (2.16) that for a finite resp. arbitrary collection of ideals $\mathfrak{a}_i \trianglelefteq_{\mathrm{i}} R$ the map $\mathbb{V}$ has the following properties

$$\begin{aligned}
\mathbb{V}\left(\sum_{i\in I} \mathfrak{a}_i\right) &= \bigcap_{i\in I} \mathbb{V}(\mathfrak{a}_i) \\
\mathbb{V}\left(\bigcap_{i=1}^{n} \mathfrak{a}_i\right) &= \bigcup_{i=1}^{n} \mathbb{V}(\mathfrak{a}_i)
\end{aligned}$$

This is the reason why we get a topology on $\mathrm{Spec}(R)$ by taking sets of the form $\mathbb{V}(\mathfrak{a})$ to be the closed sets of the topology - this is guaranteed in the easy proposition (6.12.(ii)). It is this topology that we introduce in the next definition. Also it is clear, that for any ideals $\mathfrak{a}$, $\mathfrak{b}$ of R, respectively subsets $\mathcal{P}$, $\mathcal{Q} \subseteq \mathrm{Spec}(R)$ the maps $\mathbb{V}$ and $\mathbb{I}$ are order-reversing, that is $\mathfrak{a} \subseteq \mathfrak{b}$ turns into $\mathbb{V}(\mathfrak{b}) \subseteq \mathbb{V}(\mathfrak{a})$ and likewise $\mathcal{P} \subseteq \mathcal{Q}$ turns into $\mathbb{I}(\mathcal{Q}) \subseteq \mathbb{I}(\mathcal{P})$. Also any proper ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ satisfies

$$\mathfrak{a} \;\subseteq\; \sqrt{\mathfrak{a}} \;=\; \bigcap \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p} \,\} \;=\; \mathbb{I}\big(\mathbb{V}(\mathfrak{a})\big)$$

according to (2.25.(i)) and $\mathbb{I}(\mathcal{P}) \subseteq \mathfrak{p}$ for any $\mathfrak{p} \in \mathcal{P} \subseteq \operatorname{Spec}(R)$ is trivial, such that $\mathcal{P} \subseteq \mathbb{V}(\mathbb{I}(\mathcal{P}))$ is true, as well. Then (0.22) tells us, that $(\mathbb{V}, \mathbb{I})$ forms contra-variant *Galois connection*. That is $\mathbb{V}\mathbb{I}\mathbb{V} = \mathbb{V}$ and $\mathbb{I}\mathbb{V}\mathbb{I} = \mathbb{I}$ and we obtain a 1-to-1 correspondence

$$\begin{array}{rcl} \operatorname{Srad}(R) & \longleftrightarrow & \mathcal{Z}(R) \\ \mathfrak{a} & \mapsto & \mathbb{V}(\mathfrak{a}) \\ \mathbb{I}(\mathcal{P}) & \hookleftarrow & \mathcal{P} \end{array}$$

Thereby $\mathcal{Z}(R) := \{\, \mathbb{V}(\mathfrak{a}) \mid \mathfrak{a} \trianglelefteq_{\mathrm{i}} R \,\}$ is the collection of closed subsets of $\operatorname{Spec}(R)$ just by definition and the image of $\mathbb{I}$ equals $\operatorname{Srad}(R) = \{\, \mathbb{I}(\mathcal{P}) \mid \mathcal{P} \subseteq \operatorname{Spec}(R) \,\}$, as can be seen in the following way:

Prob If $\mathfrak{a} \in \operatorname{Srad}(R)$ is a radical ideal of R, then either $\mathfrak{a} = R = \mathbb{I}(\emptyset)$ or $\mathfrak{a} \neq R$ is proper. In the latter case we have $\mathbb{I}(\mathbb{V}(\mathfrak{a})) = \sqrt{\mathfrak{a}} = \mathfrak{a}$ by (2.25.(i)), such that $\mathfrak{a}$ is contained in the image of $\mathbb{I}$, again. If conversely $\mathfrak{a} = \mathbb{I}(\mathcal{P})$, for some $\mathcal{P} \neq \emptyset$, then $\mathbb{I}(\mathcal{P})$ is a radical ideal, due to (2.22.(v)).

(8.86) Definition:
Let $(R, +, \cdot)$ be any commutative ring and $\operatorname{Spec}(R) := \{\, \mathfrak{p} \trianglelefteq_{\mathrm{i}} R \mid \mathfrak{p} \text{ is a prime ideal} \,\}$ be the collection of all prime ideals of R. Then we introduce the **Zariski topology** on $\operatorname{Spec}(R)$ in the following way: A subset $U \subseteq \operatorname{Spec}(R)$ is said to be *open*, iff

$$U \subseteq \operatorname{Spec}(R) \text{ open} \quad :\Longleftrightarrow \quad \exists\, \mathfrak{a} \trianglelefteq_{\mathrm{i}} R \,:\, U = \operatorname{Spec}(R) \setminus \mathbb{V}(\mathfrak{a})$$

The collection of closed sets of $\operatorname{Spec}(R)$ is denoted by $\mathcal{Z}(R) := \{\, \mathbb{V}(\mathfrak{a}) \mid \mathfrak{a} \trianglelefteq_{\mathrm{i}} R \,\}$ and the collection of open sets of $\operatorname{Spec}(R)$ is denoted by $\mathcal{T}(R) := \{\, \operatorname{Spec}(R) \setminus \mathbb{V}(\mathfrak{a}) \mid \mathfrak{a} \trianglelefteq_{\mathrm{i}} R \,\}$. Is R is understood, we will sometimes write $\mathcal{Z}$ or $\mathcal{T}$ for these sets, only. The topological space $(\operatorname{Spec}(R), \mathcal{T}(R))$ is said to be the (base space of the) **affine scheme** of R.

(8.87) Remark:
Let $(R, +, \cdot)$ be a commutative ring and $X := \operatorname{Spec}(R)$ its prime spectrum. Then we regard X in the Zariski topology $\mathcal{T}$ introduced above. If now $\mathfrak{p} \in X$ is point in X (i.e. any prime ideal of R), then the open neighbourhood filter of $\mathfrak{p}$ is given to be

$$\mathcal{T}(\mathfrak{p}) \;=\; \{\, X \setminus \mathbb{V}(\mathfrak{a}) \mid \mathfrak{a} \trianglelefteq_{\mathrm{i}} R,\, \mathfrak{a} \setminus \mathfrak{p} \neq \emptyset \,\}$$

More generally for any subset $P \subseteq X$ we find that the set of open neighbourhoods of P is given to be

$$\mathcal{T}(P) \;=\; \{\, X \setminus \mathbb{V}(\mathfrak{a}) \mid \mathfrak{a} \trianglelefteq_{\mathrm{i}} R,\, P \cap \mathbb{V}(\mathfrak{a}) = \emptyset \,\}$$

Prob by definition any open set $U \subseteq X$ is of the form $U = X \setminus \mathbb{V}(\mathfrak{a})$ for some ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$. Therefore $\mathfrak{p} \in U$ is equivalent, to $\mathfrak{p} \notin \mathbb{V}(\mathfrak{a})$. That is *non* $\mathfrak{a} \subseteq \mathfrak{p}$. Again this can be put as: There is some $a \in \mathfrak{a}$ with $a \notin \mathfrak{p}$, which turns into $\mathfrak{a} \setminus \mathfrak{p} \neq \emptyset$. Now for $P \subseteq X$, again $U \in \mathcal{T}(P)$ is of the form $U = X \setminus \mathbb{V}(\mathfrak{a})$. Hereby $P \subseteq X \setminus \mathbb{V}(\mathfrak{a})$ is equivalent to $P \cap \mathbb{V}(\mathfrak{a}) = \emptyset$.

The fact that $\mathcal{Z}(R)$ forms the closed set of a topology on $\mathrm{Spec}(R)$ already contains several algebraic properties of ideals. Let us take a first glance how other basic algebraic properties translate into topological properties of the spectrum:

(8.88) Proposition: (viz. 1306)
Let $(R, +, \cdot)$ be a commutative ring and $X := \mathrm{Spec}(R)$ be its prime spectrum endowed with the Zariski topology. Then we obtain the following statements

(i) For any subset $P \subseteq X$ the closure of P is given to be $\overline{P} = \mathbb{V}(\mathbb{I}(P))$.

(ii) The closed points of X are precisely the maximal ideals of R. That is for any prime ideal $\mathfrak{p} \in X$ we obtain the following equivalence

$$\{\,\mathfrak{p}\,\} \subseteq X \text{ closed} \quad \Longleftrightarrow \quad \mathfrak{p} \in \mathrm{Smax}(R)$$

(iii) For any $a \in R$ let us denote the set $B(a) := \{\,\mathfrak{p} \in X \mid a \notin \mathfrak{p}\,\}$. Such a set is called a *principal open set*, due to: (1) $B(a) = X \setminus \mathbb{V}(aR) \subseteq X$ is an open set and (2) for any $a, b \in R$ we have $B(a) \cap B(b) = B(ab)$. And thereby (3) the set $\mathcal{B} := \{\,B(a) \mid a \in R\,\}$ is a base of the Zariski-topology on X. In fact if $U = X \setminus \mathbb{V}(\mathfrak{a})$ is an open set, then we have the identity

$$U \;=\; \bigcup_{a \in \mathfrak{a}} B(a)$$

(iv) The prime spectrum of a commutative ring is a T_0-space (aka *Kolmogorov*-space): That is for any two points $\mathfrak{p}, \mathfrak{q} \in X$ with $\mathfrak{p} \neq \mathfrak{q}$ there is some open set $U \subseteq X$ such that

$$\big(\mathfrak{p} \in U \text{ and } \mathfrak{q} \notin U\big) \;\text{ or }\; \big(\mathfrak{p} \notin U \text{ and } \mathfrak{q} \in U\big)$$

(v) The prime spectrum of a commutative ring, is compact space. That is for any collection $U_i \subseteq X$ of open subsets (where $i \in I$ for some $I \neq \emptyset$) we get the implication

$$X = \bigcup_{i \in I} U_i \quad \Longrightarrow \quad \exists\, \Omega \subseteq I \text{ finite, such that } X = \bigcup_{i \in \Omega} U_i$$

(vi) If $(S, +, \cdot)$ is another commutative ring and $\varphi : R \to S$ is a homomorphism of rings then we get a continuous map (called the **comorphism**) of φ on the spectra of R and S, by virtue of

$$\varphi^* \;:\; \mathrm{Spec}(S) \to \mathrm{Spec}(R) \;:\; \mathfrak{u} \mapsto \varphi^{-1}(\mathfrak{u})$$

(vii) If $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ then the comorphism of $\varrho : R \twoheadrightarrow R/\mathfrak{a} : x \mapsto x + \mathfrak{a}$ is a closed embedding with image $\mathbb{V}(\mathfrak{a})$ [that is ϱ^* is injective, continuous and closed and thereby a homeomorphism onto $\mathbb{V}(\mathfrak{a})$]

$$\varrho^* \;:\; \mathrm{Spec}\left(R \big/ \mathfrak{a}\right) \hookrightarrow \mathrm{Spec}(R) \;:\; \mathfrak{p} \big/ \mathfrak{a} \mapsto \mathfrak{p}$$

(viii) If $U \subseteq R$ is a multiplicatively closed set, then the comorphism of $\kappa : R \to U^{-1}R : a \mapsto a/1$ is a homeomorphism onto the subset $\{\, \mathfrak{p} \in \operatorname{Spec}(R) \mid \mathfrak{p} \cap U = \emptyset \,\}$ of the spectrum of R

$$\kappa^* \;:\; \operatorname{Spec}\big(U^{-1}R\big) \;\hookrightarrow\; \operatorname{Spec}(R) \;:\; U^{-1}\mathfrak{p} \mapsto \mathfrak{p}$$

(8.89) Lemma: (viz. 1308)
Let $(R, +, \cdot)$ be a commutative ring, u, $v \in R$ and $X := \operatorname{Spec}(R)$. Recall the principal open sets $B(u) := \{\, \mathfrak{p} \in X \mid u \notin \mathfrak{p} \,\}$. Suppose we have $B(v) \subseteq B(u)$, then we get the following statements:

(i) There are some $n \in \mathbb{N}$ and $p \in R$ such that $v^n = pu$. And thereby $u/1 \in R_v$ is invertible, with inverse $(u/1)^{-1} = p/v^n$.

(ii) We obtain a homomorphism ϱ_u^v of rings (called the *canonical restriction*) from R_u to R_v by the definition below. And in truth this homomorphism is independent of the specific choice of n and p.

$$\varrho_u^v \;:\; R_u \;\to\; R_v \;:\; \frac{a}{u^m} \;\mapsto\; \frac{ap^m}{v^{mn}} \;=\; \frac{a}{1} \cdot \Big(\frac{u}{1}\Big)^{-m}$$

(iii) If even $B(u) = B(v)$, then the canonical restriction ϱ_u^v is an isomorphism of rings, with inverse homomorphism $(\varrho_u^v)^{-1} = \varrho_v^u$. And if u, v and $w \in R$, such that $B(w) \subseteq B(v) \subseteq B(u)$, then the canonical restrictions satisfy the composition property $\varrho_v^w \, \varepsilon_u^v = \varrho_u^w$.

Irreducible Components
The above proposition is a neat example of how the algebraic properties (e.g. being a homomorphism of rings) translates into topological properties (e.g. being a continuous map). One of the most important notions in algebra are prime ideals. In the following we will study the topological counterpart: irreducible sets. Minimal prime ideals of R will correspond to *irreducible components* of $X = \operatorname{Spec}(R)$, that are a refinement of the connected components of X.

(8.90) Definition: (viz. 1309)
Let $(X, \mathcal{T})$ be a topological space and $I \subseteq X$ be a subset. As always we regard I in the relative topology $\mathcal{T} \cap I$. Then I is said to be **irreducible**, iff it satisfies one of the following equivalent conditions

(a) I cannot be written as a union of two closed, proper subsets, that is: If C and $D \subseteq I$ are closed subsets, such that $I = C \cup D$, then we already have $I = C$ or $I = D$.

(b) I cannot be written as a union of finitely many closed, proper subsets, that is: Given $n \geq 1$ subsets $C_1, \ldots, C_n \subseteq I$ such that any $C_i \subseteq I$ is closed (in the relative topology), we get the implication

$$I = \bigcup_{i=1}^{n} C_i \quad \Longrightarrow \quad \exists\, k \in 1 \ldots n : I = C_k$$

(c) If I is covered by finitely closed sets then I is already contained in one of those sets, that is: Given finitely many closed subsets $C_1, \ldots, C_n \subseteq X$, we get the implication

$$I \subseteq \bigcup_{i=1}^{n} C_i \quad \Longrightarrow \quad \exists\, k \in 1 \ldots n : I \subseteq C_k$$

(d) Every two non-empty, open subsets of I have non-empty intersection, that is: If $U, V \subseteq I$ are open subsets, such that $U \neq \emptyset$ and $V \neq \emptyset$, then we also get $U \cap V \neq \emptyset$.

(e) Every non-empty, open subset of I already is dense in I (i.e. its closure in I is I). More formally: For any open subset $U \subseteq I$ with $U \neq \emptyset$ we get $\overline{U} \cap I = I$.

For the moment being let us denote $\mathcal{I} := \{ I \subseteq X \mid \text{(a)} \}$ the family of all irreducible subsets of X. Then we introduce the set of **irreducible components** of X to be the maximal irreducible subsets of X

$$\operatorname{IRR}(X) \;:=\; \mathcal{I}^* \;=\; \{ I \in \mathcal{I} \mid I \subseteq J \in \mathcal{I} \implies I = J \}$$

It is evident, that the closure $I_x := \overline{\{ x \}}$ of any point $x \in X$ of X is irreducible and we call $x \in X$ the **generic point** of I_x. If X is a T_0-space, then the generic point of a set even is unique, i.e. we then get

$$X \text{ is } T_0,\ \overline{\{ x \}} = \overline{\{ y \}} \quad\implies\quad x = y$$

Nota Not every irreducible set has a generic point: E.g. consider an infinite set X in the *cofinite topology*. That is the open sets $U \subseteq X$ are $U = \emptyset$ and those U, such that $X \setminus U$ is finite. Then any $\{ x \}$ is closed and thereby X cannot have a generic point. But as X is infinite, it is irreducible - the only closed sets apart from X are finite.

(8.91) Proposition: (viz. 1310)
Let $(X, \mathcal{T}_X)$ and $(Y, \mathcal{T}_Y)$ be any two topological spaces, then we obtain the following statements concerning irreducible sets

(i) For an arbitrary subset $I \subseteq X$ the following statements are equivalent

 (a) I is irreducible

 (b) the closure $\overline{I}$ of I is irreducible

 (c) every open subset $P \subseteq I$ of I is irreducible

(ii) Every irreducible set is contained in an irreducible component. That is for any irreducible subset $I \subseteq X$ there is some $J \in \operatorname{IRR}(X)$ such that $I \subseteq J$.

(iii) If $I \subseteq X$ is irreducible, then I is connected, in the sense of (6.34).

(iv) The image of an irreducible set under a continuous map is irreducible, again. That is if $f : X \to Y$ is continuous and $I \subseteq X$ is irreducible, then the image $f(I) \subseteq Y$ is irreducible, too.

(v) If X is a non-empty *Hausdorff space* (that is $X \neq \emptyset$ and for any two $x, y \in X$ with $x \neq y$ there are open subsets $U, V \subseteq X$ such that $x \in U$, $y \in V$ and $U \cap V = \emptyset$), then the irreducible components of X are precisely the sets containing a single point, formally

$$\operatorname{IRR}(X) \;=\; \{ \{ x \} \mid x \in X \}$$

(8.92) Proposition: (viz. 1312)

(i) Let $(R,+,\cdot)$ be an integral domain, then $\mathrm{Spec}(R)$ is an irreducible topological space (in the Zariski topology) and the zero-ideal $0 \trianglelefteq_{\mathfrak{i}} R$ is the generic point of $\mathrm{Spec}(R)$.

(ii) If $(R,+,\cdot)$ is a reduced commutative ring (i.e. $\mathrm{NIL}(R) = 0$) such that $\mathrm{Spec}(R)$ is irreducible (in the Zariski topology), then R already is an integral domain.

(iii) We can generalize (i): If $(R,+,\cdot)$ is any commutative ring and $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$ is a prime ideal, then $\mathbb{V}(\mathfrak{p}) \subseteq \mathrm{Spec}(R)$ is an irreducible set (in the Zariski topology) and $\mathfrak{p}$ is its generic point. And thereby we find the equivalence of the following two statements, for any subset $I \subseteq \mathrm{Spec}(R)$:

 (a) $I = \mathbb{V}(\mathfrak{p})$ for some prime ideal $\mathfrak{p} \trianglelefteq_{\mathfrak{i}} R$

 (b) I is a non-empty, closed irreducible subset of $\mathrm{Spec}(R)$

(iv) Let $(R,+,\cdot)$ be a commutative ring and abbreviate its prime spectrum by $X := \mathrm{Spec}(R)$ (in the Zariski topology). Then the irreducible components of R are precisely the sets $\mathbb{V}(\mathfrak{p})$, where $\mathfrak{p}$ is a minimal prime ideal of R. Formally that is the identity, of

$$\mathrm{IRR}(X) \;=\; \{\, \mathbb{V}(\mathfrak{p}) \;\mid\; \mathfrak{p} \in \mathrm{Smin}(R) \,\}$$

(8.93) Proposition: (viz. 1311)
Let $(X,\mathcal{T})$ be a non-empty topological space, then the irreducible components of X satisfy the properties

- $X = \bigcup \mathrm{IRR}(X)$
- $\forall\, I \in \mathrm{IRR}(X)$ we get $I \neq \emptyset$ is non-empty
- $\forall\, I \in \mathrm{IRR}(X)$ we get $I \subseteq X$ is closed and irreducible
- $\forall\, I \subseteq X$ irreducible $\exists\, J \in \mathrm{IRR}(X)$ with $I \subseteq J$

And for any finite family of subsets $\mathcal{I}$ of X (i.e. $\mathcal{I} \subseteq \mathcal{P}(X)$ and $\#\mathcal{I} < \infty$) we have $\mathcal{I} = \mathrm{IRR}(X)$ if and only if $\mathcal{I}$ satisfies all of the following three properties

(1) $X = \bigcup \mathcal{I}$

(2) $\forall\, I \in \mathcal{I}$ we get $I \subseteq X$ is closed and irreducible

(3) $\forall\, I \in \mathcal{I}$ we get $X \neq \bigcup \{\, J \in \mathcal{I} \mid I \neq J \,\}$

(8.94) Proposition: (viz. 1313)
Let $(X,\mathcal{T})$ be a topological space and fix an open subset $U \subseteq X$ (inheriting the relative topology). Then let us denote the closed, irreducible subsets of X and U respectively by

$$\begin{aligned} \mathcal{I}(X) &:= \{\, J \subseteq X \mid J \text{ closed and irreducible} \,\} \\ \mathcal{I}(U) &:= \{\, I \subseteq U \mid I \text{ closed and irreducible} \,\} \end{aligned}$$

Then we obtain a one-to-one correspondence between the non-empty sets of $\mathcal{I}(U)$ and the sets of $\mathcal{I}(X)$ with non-empty $J \cap U$, given by (where the closure $\overline{I}$ is taken in X)

$$\begin{array}{rcl} \{\, I \in \mathcal{I}(U) \mid I \neq \emptyset \,\} & \longleftrightarrow & \{\, J \in \mathcal{I}(X) \mid J \cap U \neq \emptyset \,\} \\ I & \mapsto & \overline{I} \\ J \cap U & \hookleftarrow & J \end{array}$$

This correspondence even correlates the irreducible components of U to the irreducible components of X with non-empty intersection $J \cap U$

$$\begin{array}{rcl} \operatorname{IRR}(U) & \longleftrightarrow & \{\, J \in \operatorname{IRR}(X) \mid J \cap U \neq \emptyset \,\} \\ I & \mapsto & \overline{I} \\ J \cap U & \hookleftarrow & J \end{array}$$

And this correspondence also preserves generic points - let $J \in \mathcal{I}(X)$ such that $J \cap U \neq \emptyset$ and consider any $x \in X$. Then we get the equivalence (where the closure of $\{\, x \,\}$ on the left-hand side is to be taken in U and the closure on the right-hand side is taken in X)

$$J \cap U = \overline{\{\, x \,\}} \iff J = \overline{\{\, x \,\}}$$

Topological Dimension

In the previous section we have put tremendous effort into establishing a theory of dimension of commutative rings. Let us take a look through our new looking glass at these concepts. The topological side of this dimension theory is easier than the algebraic side. So let us now introduce the notions fitting for the spectrum of a noetherian ring. In a Hausdorff space $(X, \mathcal{T})$ the irreducible components of X are of the form $\{\, x \,\}$ for some $x \in X$, so we get $\operatorname{tdim}(X) = 0$ and no new insights. But the spectrum of a ring is not hausdorff and this is where the theory will shine.

(8.95) Definition:

Let $(X, \mathcal{T})$ be a topological space, as in (8.94) let us denote the set of closed irreducible subsets of X by $\mathcal{I}(X)$ again. Then we define the **(topological) dimension** of X to be the maximal length of an ascending chain of closed, irreducible subsets of X. Formally we let $\operatorname{tdim}(\emptyset) := -1$ and if $X \neq \emptyset$, then

$$\operatorname{tdim}(X) \;:=\; \sup \left\{ d \in \mathbb{N} \;\middle|\; \begin{array}{l} \exists\, I_0, \ldots, I_d \in \mathcal{I}(X) \text{ such that} \\ I_0 \neq \emptyset \text{ and } I_0 \subset \ldots \subset I_d \end{array} \right\} \in \mathbb{N} \cup \{\infty\}$$

(8.96) Proposition: (viz. 1314)

Let $(X, \mathcal{T})$ be a topological space, $C \subseteq X$ be a closed and $U \subseteq X$ be an open subset of X. Then the following statements are true

(i) $\operatorname{tdim}(C) \leq \operatorname{tdim}(X)$ and $\operatorname{tdim}(U) \leq \operatorname{tdim}(X)$

(ii) If X is irreducible and $\operatorname{tdim}(X) < \infty$ finite-dimensional and $C \neq X$ even $\operatorname{tdim}(C) < \operatorname{tdim}(X)$

(iii) If $\operatorname{tdim}(X) < \infty$ is finite-dimensional, then the dimension of X equals the maximal dimension of its irreducible components, formally that is

$$\operatorname{tdim}(X) \quad = \quad \max\{\, \operatorname{tdim}(I) \mid I \in \operatorname{IRR}(X) \,\}$$

(8.97) Definition: (viz. 1314)
The topological space $(X, \mathcal{T})$ is said to be **noetherian**, iff one (and hence all) of the following five equivalent conditions is satisfied

(a) Every open subset U of X is compact in X, in the sense of (6.17).

$$P \subseteq X \text{ open} \quad \Longrightarrow \quad P \subseteq X \text{ compact}$$

(b) Every family of open subsets has a maximal element, i.e. for any non-empty set $\mathcal{U} \subseteq \mathcal{T}$ there is some $U^* \in \mathcal{U}$ such that for any $U \in \mathcal{U}$ we get the implication

$$U^* \subseteq U \quad \Longrightarrow \quad U^* = U$$

(c) Every set of closed subsets has a minimal element, i.e. for any non-empty set $\mathcal{C} \subseteq \{\, X \setminus U \mid U \in \mathcal{T} \,\}$ there is some $C_* \in \mathcal{C}$ such that for any $C \in \mathcal{C}$ we get the implication

$$C \subseteq C_* \quad \Longrightarrow \quad C = C_*$$

(d) Every ascending chain of open sets becomes stationary, that is: If $U_k \subseteq X$ is an open subset (where $k \in \mathbb{N}$) such that $U_0 \subseteq U_1 \subseteq \ldots \subseteq U_n \subseteq \ldots$ then there is some $n \in \mathbb{N}$ such that for any $k \in \mathbb{N}$ we get $U_{n+k} = U_n$.

(e) Every descending chain of closed sets becomes stationary, that is: If $C_k \subseteq X$ is a closed subset (where $k \in \mathbb{N}$) such that $C_0 \supseteq C_1 \supseteq \ldots \supseteq C_n \supseteq \ldots$ there is some $n \in \mathbb{N}$ such that for any $k \in \mathbb{N}$ we get $C_{n+k} = C_n$.

(8.98) Proposition: (viz. 1315)
Let $(X, \mathcal{T})$ be a noetherian topological space. A subset $L \subseteq X$ is said to be **locally closed**, iff it is of the form $L = U \cap C$ for some open set $U \subseteq X$ and some closed set $C \subseteq X$. And thereby we obtain

(i) X has only finitely many irreducible components, i.e. $\#\operatorname{IRR}(X) < \infty$.

(ii) If X is both, noetherian and hausdorff, then X already is a finite set $\#X < \infty$ and carries the discrete topology $\mathcal{T} = \mathcal{P}(X)$.

(iii) Any locally closed subset $L \subseteq X$ is compact.

(iv) Any locally closed subset $L \subseteq X$ becomes a noetherian topological space in the relative topology $\mathcal{T} \cap L$ it inherits from X.

(v) *Noetherian Induction:* Let φ be any property of the closed subsets of X, i.e. φ is a mapping of the form $\varphi : \{ X \setminus U \mid U \in \mathcal{T} \} \to \{ \text{true, false} \}$ such that $\varphi(\emptyset)$ and for any non-empty closed subset $D \subseteq X$ we get the induction hypothesis

$$\Big(\forall\, C \subseteq X \text{ closed, with } C \subset D : \varphi(C)\Big) \quad \Longrightarrow \quad \varphi(D)$$

then φ is already true for the entire space X, that is we also get $\varphi(X)$.

(8.99) Lemma: (viz. 1316) **Topological Laskar-Noether Theorem**
Let $(N, \mathcal{T})$ be a noetherian topological space and $X \subseteq N$ be a closed subset. Then there are uniquely determined $r \in \mathbb{N}$ and $X_1, \ldots, X_r \subseteq N$ such that the following statements (1), (2), (3) and (4) are true. And in this case we also obtain statement (5), where

(1) $X = X_1 \cup \cdots \cup X_r$

(2) $\forall\, i \neq j \in 1 \ldots r$ we get $X_i \not\subseteq X_j$

(3) $\forall\, i \in 1 \ldots r$ we get $X_i \subseteq X$ is closed

(4) $\forall\, i \in 1 \ldots r$ we get X_i is irreducible

(5) $\operatorname{IRR}(X) = \{ X_1, \ldots, X_r \}$

(8.100) Corollary: (viz. 1317)
Let $(X, \mathcal{T})$ be a noetherian topological space in which for any $x \in X$ the set $\{ x \} \subseteq X$ is closed (that is X is a so-called T_1-space). Then X is finite if and only if $\operatorname{tdim}(X) = 0$ and in this case the irreducible components are precisely the one-point sets $\operatorname{IRR}(X) = \{\{x\} \mid x \in X\}$

$$1 \leq \#X < \infty \quad \Longleftrightarrow \quad \operatorname{tdim}(X) = 0$$

(8.101) Example:
If $(F, +, \cdot)$ is any field, then the space $N := F^n$ is an irreducible, noetherian T_1-space in the Zariski-topology. And if $X \subseteq N$ is a closed set - that is $X = \mathbb{V}(\mathfrak{a})$ for some ideal $\mathfrak{a} \trianglelefteq_{\mathrm{i}} F[t_1, \ldots, t_n]$, then by (8.99) X is a noetherian space in the relative topology, as well. The irreducible components of X are the $X_i = \mathbb{V}(\mathfrak{p}_i) \subseteq X$, where the $\mathfrak{p}_i \trianglelefteq_{\mathrm{i}} F[t_1, \ldots, t_n]$ are the prime ideals, that are minimal over $\mathfrak{a}$.

(8.102) Example:
Consider any field $(F, +, \cdot)$ and let us denote $R := F[t_k \mid k \in \mathbb{N}]$ the polynomial ring in countably many variables and $X := \operatorname{Spec}(R)$. Then R is *not* noetherian, since $\mathfrak{p}_k := \langle t_0, \ldots, t_k \rangle_{\mathrm{i}} \trianglelefteq_{\mathrm{i}} R$ forms a strictly ascending chain $\mathfrak{p}_0 \subset \mathfrak{p}_2 \subset \ldots$ of prime ideals. Consequently $I_k := \mathbb{V}(\mathfrak{p}_k)$ forms a strictly descending chain $I_0 \supset I_1 \supset I_2 \supset \ldots$ of closed, irreducible subsets. That is X is not a noetherian topological space. But as R is an integral domain X is an irreducible topological space: $X = \mathbb{V}(0)$ and 0 is a minimal prime ideal of R. That is X is the one and only irreducible component $\operatorname{IRR}(X) = \{ X \}$ of X. In particular there are topological spaces with finitely many irreducible components that are *not* noetherian.

(8.103) Theorem: (viz. 1317)
Let $(X, \mathcal{T})$ be a noetherian topological space, then the irreducible components are a refinement of the connected components of X in the following sense: First of all X only has finitely many connected components. More precisely it cannot have more connected components than irreducible components

$$\#\mathrm{cnc}(X) \;\leq\; \#\mathrm{irr}(X) \;<\; \infty$$

And the connected components induce a partition of the irreducible components in the following way: For any connected component $K \in \mathrm{cnc}(X)$ let us denote $\mathcal{I}(K) := \{\, I \in \mathrm{irr}(X) \mid I \subseteq K \,\}$ the set of all irreducible components inside K. Then the $\mathcal{I}(K)$ are pairwise disjoint (i.e. for any $K, L \in \mathrm{cnc}(X)$ we get $\mathcal{I}(K) \cap \mathcal{I}(L) \neq \emptyset \implies K = L$) and we get the identiites

$$\begin{aligned} \mathrm{irr}(X) &= \bigcup \{\, \mathcal{I}(K) \mid K \in \mathrm{cnc}(X) \,\} \\ K &= \bigcup \mathcal{I}(K) \end{aligned}$$

8.9 Regular Local Rings

In algebraic geometry one is interested in the dimension of a variety X in one of its points $x \in X$. This can be gleaned by using the ring of regular local functions $\mathcal{O}_x(X)$ as a looking glass, which is a local ring. So in this section we study the dimension of localisations of rings an specifically local rings. In a *regular* point $x \in X$ the dimension of the tangent space agrees with the local dimension of X, e.g. a line is the tangent space at a point on a plane curve. But if the curve intersects with itself there are two linearly independent tangent vectors at the junction. That is the dimension of the tangent space may jump up at certain points, that are called *singular* points of X. We would like to identify and manage such singular points.

(8.104) Proposition: (viz. 1318)
Let $(R, +, \cdot)$ be a local, noetherian ring with maximal ideal $\mathfrak{m}$ and denote the *residue field* of R modulo $\mathfrak{m}$ by $E := R/\mathfrak{m}$. We now regard $\mathfrak{m}$ as an R-module, then $\mathfrak{m}/\mathfrak{m}^2$ becomes an E-vector space under the following scalar multiplication:

$$(a + \mathfrak{m})(m + \mathfrak{m}^2) \;:=\; (am) + \mathfrak{m}^2$$

As $\mathfrak{m}$ also is an R-module we may look at the number of generators required for $\mathfrak{m}$, that is elements $m_1, \ldots, m_n \in R$ such that $\mathfrak{m} = Rm_1 + \cdots + Rm_n$. Thereby we find that for any elements $m_1, \ldots, m_n \in R$ the following two statements are equivalent

(a) $\{ m_1, \ldots, m_n \}$ generates $\mathfrak{m}$ as an R-module

(b) $\{ m_1 + \mathfrak{m}^2, \ldots, m_n + \mathfrak{m}^2 \}$ generates $\mathfrak{m}/\mathfrak{m}^2$ as an E-vector-space

Recall that the minimal number of generators requires for $\mathfrak{m}$ is called the *rank* of $\mathfrak{m}$, denoted by $\operatorname{rank}_R(\mathfrak{m})$. Then we find that this number equals the dimension of $\mathfrak{m}/\mathfrak{m}^2$ as an E-vector-space:

$$\dim_E \left(\mathfrak{m} \Big/ \mathfrak{m}^2 \right) \;=\; \operatorname{rank}_R(\mathfrak{m})$$

(8.105) Remark: $(\diamondsuit)$
We want to append a word on the geometric idea behind $\mathfrak{m}/\mathfrak{m}^2$, without going into details, as this is a theory of its own. In algebraic geometry we regard the ring $\mathcal{O}_x(X)$ of local regular functions of a variety X. These are functions $r : U \subseteq X \to \mathbb{F}$ that are defined on a dense open subset $x \in U \subseteq X$ that can locally be written as the quotient of polynomial functions. They build up a local ring with maximal ideal $\mathfrak{m}_x(X)$ of those local regular functions, that vanish $r(x) = 0$ at x. Thinking of a Taylor expansion of r the residue class $r + \mathfrak{m}_x(X)^2$ is the linear part of r (it has no constant term, as $r(x) = 0$ and the higher order terms are eaten up by $\mathfrak{m}_x(X)^2$). What remains is the linear freedom a local regular function can have at x. Thus $\mathfrak{m}_x(X)/\mathfrak{m}_x(X)^2$ is the (co)tangential space of X at the point $x \in X$. Therefore its dimension is (apart from singularities) the dimension of X itself. And the above proposition ascertains, that this is just the same, as the minimal number of generators needed for $\mathfrak{m}_x(X)$.

(8.106) Proposition: (viz. 1319)
Let $(R,+,\cdot)$ be a local ring with maximal ideal $\mathfrak{m}$. Suppose $\operatorname{kdim}(R) < \infty$ is finite-dimensional, then for any prime ideal $\mathfrak{p} \in \operatorname{Spec}(R)$ we find the following equivalence

$$\mathfrak{p} = \mathfrak{m} \iff \operatorname{height}(\mathfrak{p}) = \operatorname{height}(\mathfrak{m})$$

(8.107) Lemma: (viz. 1319)
Let $(R,+,\cdot)$ be a noetherian, local ring with maximal ideal $\mathfrak{m}$. Then the Krull-dimension of R cannot exceed the minimal number of generators required for $\mathfrak{m}$, that is we find

$$\operatorname{kdim}(R) = \operatorname{height}(\mathfrak{m}) \leq \operatorname{rank}(\mathfrak{m}) < \infty$$

and the Krull-dimension equals the minimal number d of elements $a_1,\ldots,a_d$ of R such that $\mathfrak{m}$ is a prime ideal minimal over the ideal $\mathfrak{a} := a_1R + \cdots + a_dR$. Formally that is the identity

$$\operatorname{kdim}(R) = \min\left\{ d \in \mathbb{N} \;\middle|\; \begin{array}{l} \exists\, a_1,\ldots,a_d \in R \text{ such that} \\ a_1R + \cdots + a_dR \subseteq \mathfrak{m} \text{ is minimal} \end{array} \right\}$$

Nota by (2.139) the property that "$\mathfrak{m}$ is a minimal prime ideal over $\mathfrak{a}$" can be formulated in many different ways. A commonly used alternative is $\mathbb{V}(\mathfrak{a}) = \{\mathfrak{m}\}$.

Let $a_1,\ldots,a_d \in R$ such that $\mathfrak{m}$ is a minimal prime ideal over $\mathfrak{a} := \langle a_1,\ldots,a_d\rangle_{\mathfrak{i}}$. It may happen that these elements do not generate $\mathfrak{m}$ as an R-module, that we need some more $\mathfrak{m} = \langle m_1,\ldots,m_n\rangle_{\mathfrak{i}}$. Then the above propositions tell us that the difference in the dimensions n of the cotangent space $\mathfrak{m}/\mathfrak{m}^2$ and the dimension d of R is derived from those elements that were missing to build up $\mathfrak{m}$. A neat special case is $n = d$, that is when the $a_1,\ldots,a_d$ are already sufficient, to build up $\mathfrak{m}$.

(8.108) Definition:
If $(R,+,\cdot)$ is a local ring, having the maximal ideal $\mathfrak{m}$, then a subset of elements $\{a_1,\ldots,a_d\} \subseteq R$ are said to be a **local system of parameters** of R, iff it satisfies the following two properties

(1) $d = \operatorname{kdim}(R)$

(2) $\mathfrak{m}$ is a minimal prime ideal over $a_1R + \cdots + a_dR$

A commutative ring $(R,+,\cdot)$ is said to be a **regular local ring**, iff (1) R is a local ring, (2) R is a noetherian ring and (3) if $\mathfrak{m}$ is the maximal ideal of R, then $\operatorname{kdim}(R) = \operatorname{rank}(\mathfrak{m})$.

Nota if R is a noetherian, local ring, then R has a local system of parameters, by (8.107). And if R is a regular local ring and $\mathfrak{m} = m_1R + \cdots + m_nR$, where $n = \operatorname{rank}(\mathfrak{m})$ is minimal, then $\{m_1,\ldots,m_n\}$ is a local system of parameters of R.

(8.109) Proposition: (viz. 1319)
Let $(R,+,\cdot)$ be a local, noetherian ring with maximal ideal $\mathfrak{m}$ and consider some elements $a_1,\ldots,a_m \in \mathfrak{m}$ and let us denote $\mathfrak{a} := a_1R + \cdots + a_mR$. Then the following statements are true

(i) The quotient ring $R/\mathfrak{a}$ is a noetherian, local ring with maximal ideal $\mathfrak{m}/\mathfrak{a}$ and the Krull-dimension of this ring is at least
$$\operatorname{kdim}\left(R\Big/\mathfrak{a}\right) \;\geq\; \operatorname{kdim}(R) - m$$

(ii) If $a_{m+1},\ldots,a_n \in \mathfrak{m}$ are elements, such that $\{\, a_1,\ldots,a_n \,\}$ is a local system of parameters of R, then $\mathfrak{m}/\mathfrak{a}$ is a prime ideal, minimal over $\langle a_{m+1}+\mathfrak{a},\ldots,a_n+\mathfrak{a}\rangle_{\mathfrak{i}}$.

(iii) The set $\{\, a_1,\ldots,a_m \,\}$ can be extended to a local system of parameters of R if and only if the Krull-dimension of $R/\mathfrak{a}$ is equal to $\operatorname{kdim}(R/\mathfrak{a}) = \operatorname{kdim}(R) - m$.

(iv) If $\operatorname{height}(\mathfrak{a}) = m$, then (1) $\{\, a_1,\ldots,a_m \,\}$ can be extended to a local system of parameters $\{a_1,\ldots,a_n\}$ (where $n = \operatorname{kdim}(R) \geq m$) of R and thereby (2) $\{a_{m+1}+\mathfrak{a},\ldots,a_n+\mathfrak{a}\}$ is a local system of parameters of $R/\mathfrak{a}$, as we also have (3) $\operatorname{kdim}(R) = \operatorname{kdim}(R/\mathfrak{a}) + \operatorname{height}(\mathfrak{a})$.

(8.110) Example:
Let $(E,+,\cdot)$ be a field and regard the ideal $\mathfrak{a} := t^3E[t]$ in the polynomial ring $E[t]$. Then we study the ring $R := E[t]/\mathfrak{a}$ and find that it features the following properties

- By construction any polynomial $f \in E[t]$ is reduced to $f[2]t^2 + f[1]t + f[0] + \mathfrak{a}$ and hence we can explicitly write R as the set $R = \left\{\, a_2t^2 + a_1t + a_0 + \mathfrak{a} \mid a_0,a_1,a_2 \in E \,\right\}$. As this representation is unique 1, x and x^2 build up an E-basis of $R:E$, where $x := t+\mathfrak{a}$, and hence $[R:E] = 3$.

- Note that $E[t]$ is a PID and by the correspondence theorem of ideals in quotients the ideal $\mathfrak{b}/\mathfrak{a}$ of R has its origin in an ideal $\mathfrak{b} = gE[t]$. Hereby $t^3E[t] \subseteq gE[t]$ turns into $g \mid t^3$ and therefore R has the following 4 ideals, precisely
$$\operatorname{Ideal}(R) \;=\; \left\{\, 0,\, x^2R,\, xR,\, R \,\right\}$$

- Of these ideals $\mathfrak{m} := xR$ is the only prime ideal and this already is maximal. That is R is a local ring and $\operatorname{Spec}(R) = \operatorname{Smax}(R)$. In particular $\operatorname{kdim}(R) = 0$. As R also in noetherian (any ideal is generated by a single element) it even is an artinian ring.

- The maximal ideal $\mathfrak{m}$ of R is of the form $\mathfrak{m} = \left\{\, a_2x^2 + a_1x \mid a_1,a_2 \in E \,\right\}$. In particular $\operatorname{rank}(\mathfrak{m}) = 1$, as $\mathfrak{m} = xR$ and $\{x\}$ is a minimal generating set of $\mathfrak{m}$. From this we see R is local and noetherian, but $\operatorname{kdim}(R) = 0 < 1 = \operatorname{rank}(\mathfrak{m})$. This means that R is *not* a regular local ring.

- Let us take a look at the cotangent space $\mathfrak{m}/\mathfrak{m}^2$: As $\mathfrak{m} = xR$ clearly $\mathfrak{m}^2 = x^2R$. Thus the elements of $\mathfrak{m} = \left\{\, a_2x^2 + a_1x \mid a_1,a_2 \in E \,\right\}$ loose their x^2-part, it only remains
$$\mathfrak{m}\Big/\mathfrak{m}^2 \;=\; \left\{\, a_1x + \mathfrak{m}^2 \mid a_1 \in E \,\right\}$$
Thus $\mathfrak{m}/\mathfrak{m}^2$ is a 1-dimensional vector space with basis $x+\mathfrak{m}^2$. The above proposition (8.104) tells us, that this is no coincidence, but a general truism.

regular sequences, [Matrsumura Theorem 36] complete intersection ring = every prime ideal satisfies height($\mathfrak{p}$) = rank($\mathfrak{p}$) Auslander-Buchsbau Theorem: any regular local ring is an UDF [Matrsumura Theroem 48] Richard E Borcherds (youtube) for examples

Hilbert-Samuel polynomial Poincaré series Hilbert-Serre theorem Artin-Rees lemma

Chapter 9

Group Theory

9.1 Basic Notions

normal subgroups, kernel+image, isomorphism theorems, quotient groups

(9.1) Example: (viz. 643)
Consider a metric space (Y,d) and a non-empty subset $\emptyset \neq X \subseteq Y$, then a map $f : X \to X$ is called a **symmetry** of X, if it reaches all points and preserves distance. That is iff

(1) f is surjective

(2) for any $x, y \in X$ we get $d(f(x),f(y)) = d(x,y)$

The set of all symmetries of X will be denoted by $\mathrm{sym}(X)$ and in fact this is a sub-group of of the permutation-group of X. That is any symmetry already is bijective and $\mathrm{sym}(X)$ is closed under composition and taking inverse.

$$\mathrm{sym}(X) \quad \leq_{\mathrm{g}} \quad S_X$$

Proof of (9.1):
First of all, we need to show that any symmetry $f : X \to X$ is injective: So pick up any $x, y \in X$ and assume $f(x) = f(y)$. As f preserves distance this would mean $0 = d(f(x),f(y)) = d(x,y)$ and hence $x = y$. This already is the injectivity.
It is also clear, that $\mathbb{1}_X \in \mathrm{sym}(X)$. And if f and g are symmetries of X, then we have $d(g(x),g(y)) = d(x,y)$ and $d(f(u),f(v)) = d(u,v)$ for any u, v, x and $y \in X$. Let us take $x = f(u)$ and $y = f(v)$ then we see

$$d\big(gf(u),gf(v)\big) \;=\; d\big(g(x),g(y)\big) \;=\; d\big(x,y\big) \;=\; d\big(f(u),f(v)\big) \;=\; d\big(u,v\big)$$

such that $gf \in \mathrm{sym}(X)$ again, as gf also is surjective. As f is invertible we also get $u = f^{-1}(x)$ and $v = f^{-1}(y)$ such that we also find $f^{-1} \in \mathrm{sym}(X)$ (and hence $\mathrm{sym}(X)$ is a group contained in S_X) from the equation

$$d\big(f^{-1}(x),f^{-1}(y)\big) \;=\; d\big(u,v\big) \;=\; d\big(f(u),f(v)\big) \;=\; d\big(x,y\big)$$

□

conjugation, sylow theorems, p-q theorem, ordered groups, representation theory, invariant theory

9.2 Group Actions

(9.2) Definition:
Let $(G, \circ)$ be a group and X be an arbitrary set, then a map $\mu : G \times X \to X$ (written as $\mu : (g, x) \mapsto gx$) is said to be an **operation** of G on X, iff it satisfies one of the following two equivalent conditions

(a) $G \to S_X : g \mapsto T_g$ where $T_g : X \to X : x \mapsto gx$ is a group-homomorphism

(b) $\forall\, g, h \in G$ and $\forall\, x \in G$ we get the properties $ex = x$ and $(gh)x = g(hx)$

And in this case we define the following notions: for any $x \in X$ we define the **orbit** $Gx \subseteq X$ and the **stabilizer** $G^x \subseteq G$. And for any $g \in G$ we also define the **fixed point set** $X^g \subseteq X$ and the set X^G of **invariants**

$$\begin{aligned} Gx &:= \{\, gx \mid g \in G \,\} \\ G^x &:= \{\, g \in G \mid gx = x \,\} \\ G^X &:= \{\, g \in G \mid \forall\, x \in X : gx = x \,\} \\ X^g &:= \{\, x \in X \mid gx = x \,\} \\ X^G &:= \{\, x \in X \mid \forall\, g \in G : gx = x \,\} \end{aligned}$$

Finally a subset $A \subseteq X$ is said to be G-**invariant** iff for any $g \in G$ we get

$$gA := \{\, gx \mid x \in A \,\} \subseteq A$$

(9.3) Example:

(i) If $X \neq \emptyset$ is any non-empty set then any subgroup $S \leq_{\mathfrak{g}} S_X$ of the permutation group S_X operates on X in a most obvious way

$$S \times X \to X \;:\; (\sigma, x) \mapsto \sigma(x)$$

(ii) By (1.12.(ii)) any group G operates on itself, by multiplication from the left, that is we get an operation on G by

$$G \times G \to G \;:\; (g, h) \mapsto gh$$

(iii) Finally any group G operates on itself by *conjugation*, that is we obtain another action of G on G by letting

$$G \times G \to G \;:\; (g, h) \mapsto h^g := ghg^{-1}$$

Prob first of all it is clear that for any $x \in G$ we have $x^e = exe^{-1} = x$. Also for any $g, h \in G$ we can compute $x^{gh} = (gh)x(gh)^{-1} = ghxh^{-1}g^{-1} = g(x^h)g^{-1} = (x^h)^g$, so that both properties are satisfied.

(9.4) Proposition: (viz. 706)

(i) It is easy to see that an operation $G \times X \to X$ defines an equivalence relation on X by letting $x \sim y \;:\Longleftrightarrow\; \exists\, g \in G : y = gx$. And the equivalence classes of this relation clearly are the orbits

Gx. The quotient set of X under this relation is denoted by

$$X\big/_G \;:=\; \{\, Gx \mid x \in X \,\}$$

(ii) It also is immedeately clear that the stabilizer $G^x \leq_g G$ is a subgroup of G. Another well-known fact is the following 1-to-1 correspondence

$$Gx \longleftrightarrow G\big/_{G^x} \;:\; gx \mapsto gG^x$$

(iii) If $A \subseteq X$ is G-invariant, then for any $g \in G$ we have $gA = A$. And we can thereby restrict ϱ to an operation of G on A, that is

$$\varrho \;:\; G \times A \to A \;:\; (g,x) \mapsto gx$$

(iv) If A is G-invariant, then the complement $X \setminus A$ is G-invariant, too.

(v) **Orbit Formulas**: If $(G,\circ)$ is a finite group, that operates on the finite set X, then (for any $x \in X$) the following equations are true

$$\begin{aligned} \#Gx &= \frac{\#G}{\#G^x} \\ \#X &= \#G \cdot \sum_{Gx \in X/G} \frac{1}{\#G^x} \end{aligned}$$

(vi) **Formula of Burnside**: If $(G,\circ)$ is a finite group, that operates on the finite set X, then the following equation holds true

$$\#G \cdot \#X\big/_G \;=\; \sum_{g\in G} \#X^g \;=\; \sum_{x\in X} \#G^x$$

(9.5) Definition:
Let $(G,\circ)$ be a group and $(\mathbb{F},+,\cdot)$ be any field. Now a group-homomorphism $\chi : G \to \mathbb{F}^*$ from G to the multiplicative group $\mathbb{F}^*$ is called a **character** of G.

(9.6) Proposition: (viz. 646)
Let $(G,\circ)$ be any group and $(\mathbb{F},+,\cdot)$ be any field. If now $\chi_1,\ldots,\chi_r : G \to \mathbb{F}^*$ are pairwise distinct characters of G (i.e. for any $i \neq j \in 1\ldots r$ we have $\chi_i \neq \chi_j$) then the set $\{\,\chi_1,\ldots,\chi_r\,\} \subseteq \mathcal{F}(G,\mathbb{F})$ already is $\mathbb{F}$-linear independent (as $\mathbb{F}$-valued functions).

(9.7) Definition:
Let $(G,\circ)$ be any group and R be a commutative ring. Then $\mu : G \times R \to R$ is said to be an **algebraic operation**, iff we get the properties

(1) $\mu : G \times R \to R$ is an operation of G on R

(2) for any $g \in G$ the map $T_g : R \to R : a \mapsto ga$ is a homomorphism

And in this case we define the **invariant ring** under the operation μ to be

$$R^G \;:=\; \{\, a \in R \mid \forall\, g \in G : ga = g \,\}$$

Nota as T_g is bijective with $T_g^{-1} = T_{g^{-1}}$ we find that (2) already implies that any T_g even is an automorphism of the ring R. And it is immediately clear that the invariant ring $R^G \leq_{\mathrm{r}} R$ is a sub-ring of R.

(9.8) Proposition: (viz. 648)
Let G be a group, R be a commutative ring and A be a commutative monoid. If now $\mu : G \times R \to R$ is an algebraic operation, then this canonically induces an algebraic operation $G \times R[A] \to R[A]$ on the group ring $R[A]$, by

$$G \times R[A] \to R[A] \;:\; (g, f) \mapsto \sum_{\alpha \in A} (gf[\alpha])t^{\alpha}$$

And for this operation we obtain the following identity of the invariant rings

$$R[A]^G \;=\; R^G[A]$$

(9.9) Proposition: (viz. 647)
Let $G \times R \to R : a \mapsto ga$ be an algebraic operation of the group G on the commutative ring R. Let now $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ be any ideal, then we get

(i) $\mathfrak{a}^G := \{\, a \in \mathfrak{a} \mid \forall\, g \in G : ga = a \,\} = \mathfrak{a} \cap R^G \trianglelefteq_{\mathrm{i}} R^G$

(ii) If $\mathfrak{a}$ is an G-invariant ideal (that is $g\mathfrak{a} \subseteq \mathfrak{a}$ for any $g \in G$) then we obtain an algebraic operation of G on the quotient ring, via

$$G \times {}^{R}\!\Big/_{\mathfrak{a}} \to {}^{R}\!\Big/_{\mathfrak{a}} \;:\; (g, b + \mathfrak{a}) \mapsto gb + \mathfrak{a}$$

(iii) And in case $\mathfrak{a}$ is an G-invariant ideal, then we obtain a well-defined, injective homomorphism of rings by virtue of

$$R^G \Big/_{\mathfrak{a}^G} \hookrightarrow \left({}^{R}\!\Big/_{\mathfrak{a}}\right)^G \;:\; b + \mathfrak{a}^G \mapsto b + \mathfrak{a}$$

(9.10) Proposition: (viz. 647)
Let $G \times X \to X : (g, x) \mapsto gx$ be a group operation and let R be a commutative ring. Further consider $A := \mathcal{F}(X, R)$ the R-algebra of functions from X to R. Then we obtain an algebraic operation of G on A by letting

$$G \times A \to A \;:\; (g, f) \mapsto \big(x \mapsto f(g^{-1}x)\big)$$

And if $M \subseteq X$ is a G-invariant subset (that is $gM \subseteq M$ for any $g \in G$), then $\mathbb{I}(M) := \{\, f \in A \mid \forall\, x \in M : f(x) = 0 \,\}$ is a G-invariant ideal (that is $\mathbb{I}(M) \trianglelefteq_{\mathrm{i}} A$ is an ideal and $g\mathbb{I}(M) \subseteq \mathbb{I}(M)$ for any $g \in G$). And in this case we finally we obtain the isomorphy

$$A^G \Big/_{\mathbb{I}(M)^G} \;\xrightarrow{\sim}\; \left(A \Big/_{\mathbb{I}(M)}\right)^G \;:\; f + \mathbb{I}(M)^G \mapsto f + \mathbb{I}(M)$$

Proof of (9.6):
If $r = 1$ then the linear independance is clear, as $\chi_1 \neq 0$. So pick up the minimal number $k \geq 2$ such that there are $a_1 \ldots, a_k \in \mathbb{F}^*$ and (pairwise distinct) $i_1, \ldots, i_k \in 1 \ldots r$ satisfying

$$a_1\chi_{i_1} + \cdots + a_k\chi_{i_k} \;=\; 0$$

renumbering the χ_i we may assume $i_1 = 1$ and $i_2 = 2$ and so on until $i_k = k$. Let us now denote $b_i := a_i/a_k$ then we obtain the central equation

$$\sum_{i=1}^{k-1} b_i\chi_i + \chi_k \;=\; 0$$

As $\chi_1 \neq \chi_k$ (remember $k \geq 2$) there is some $h \in G$ such that $\chi_1(h) \neq \chi_k(h)$. For any $g \in G$ let us now insert gh into the central equation, this yields

$$\sum_{i=1}^{k-1} b_i\chi_i(g)\chi_i(h) + \chi_k(g)\chi_k(h) \;=\; 0$$

On the other hand (for any $g \in G$ we may first insert g into the central equation and afterwards multiply with $\chi_k(h)$. This yields another equation

$$\sum_{i=1}^{k-1} b_i\chi_i(g)\chi_k(h) + \chi_k(g)\chi_k(h) \;=\; 0$$

Subtraction these two equations we obtain another identity (for any $g \in G$)

$$\sum_{i=1}^{k-1} b_i\big(\chi_k(h) - \chi_k(h)\big)\chi_i(g) \;=\; 0$$

As any $c_i := b_i(\chi_k(h) - \chi_k(h)) \in \mathbb{F}$ is scalar we have found a linear dependence with *fewer* that k elements. As k has been minimal this can only be if $c_i = 0$ for any $i \in 1 \ldots (k-1)$. But by construction we have $c_1 \neq 0$, a contradiction. Thus k could not have be chosen in the first place and this is just the linear independence of the χ_i. □

Proof of (9.9):

(i) From the definition of $\mathfrak{a}^G$ it is clear that $\mathfrak{a}^G = \mathfrak{a} \cap R^G$. Yet $R : R^G$ is a ring extension and hence it is a general fact that $\mathfrak{a} \cap R^G \trianglelefteq_{\mathfrak{i}} R^G$.

(ii) We first prove the well-definedness of the operation: consider b, $b' \in R$ with $b + \mathfrak{a} = b' + \mathfrak{a}$. That is $b' - b \in \mathfrak{a}$ and hence (as $\mathfrak{a}$ is G-invariant) $gb' - gb = g(b' - b) \in g\mathfrak{a} \subseteq \mathfrak{a}$. And this again yields $gb + \mathfrak{a} = gb' + \mathfrak{a}$. Now as $b \mapsto gb + \mathfrak{a}$ is nothing but the composition of $b \mapsto gb \mapsto gb + \mathfrak{a}$ we also find that $b + \mathfrak{a} \mapsto gb + \mathfrak{a}$ is a homomorphism. That is the operation even is algebraic.

(iii) Let us first consider $R^G \to (R/\mathfrak{a})^G : b \mapsto b + \mathfrak{a}$. This clearly is a well-dfined homomorphism as $g(b + \mathfrak{a}) = gb + \mathfrak{a} = b + \mathfrak{a}$. And the kernel of this homomorphism clearly is $\{\, b \in R^G \mid b \in \mathfrak{a} \,\} = \mathfrak{a} \cap R^G = \mathfrak{a}^G$. Hence the map in the claim is well-defined and injective.

□

Proof of (9.10):
As $ef(x) = f(e^{-1}x) = f(x)$ we clearly have $ef = f$ for any $f \in A$. And given g, $h \in G$, $f \in A$ and $x \in X$ it is straightforward to compute

$$(h(gf))(x) \;=\; (gf)(h^{-1}x) \;=\; f(g^{-1}h^{-1}x) \;=\; f((gh)^{-1}x) \;=\; ((gh)f)(x)$$

Thus $G \times A \to A$ is a group action. And the operations of A are point-wise it is clear that this operation also is algebraic. Next we prove that $\mathbb{I}(M)$ is a G-invariant ideal. The properties of an ideal are immediatley clear. Let us consider $f \in \mathbb{I}(M)$, $g \in G$ and any $x \in M$. As M is G-invariant we get $g^{-1}x \in g^{-1}M \subseteq M$. And as $f \in \mathbb{I}(M)$ this yields $(gf)(x) = f(g^{-1}x) = 0$. As x has been arbitrary, this proves $gf \in \mathbb{I}(M)$, which also yields the G-invariance $g\mathbb{I}(M) \subseteq \mathbb{I}(M)$. It remains to prove

$$A^G \Big/ \mathbb{I}(M)^G \;\xrightarrow{\sim}\; \left(A \Big/ \mathbb{I}(M)\right)^G \;:\; f + \mathbb{I}(M)^G \mapsto f + \mathbb{I}(M)$$

We have already proved the well-definedness and injectivity of this map in (9.10). For the surjectivity we are given some $f + \mathbb{I}(M)$ which is G-invariant. That is $gf + \mathbb{I}(M) = f + \mathbb{I}(M)$ for any $g \in G$. In other words that is $f(g^{-1}x) = (gf)(x) = f(x)$ for any $g \in G$. Let us denote $1_M : X \to R$ the characteristic function of M and let $\widetilde{f} := 1_M f$. If $x \notin M$ then we clearly have $\widetilde{f}(x) = 1_M(x)f(x) = 0$. And as $X \setminus M$ is G-invariant as well, we get $1_M(g^{-1}x) = 0$ and hence $(g\widetilde{f})(x) = \widetilde{f}(g^{-1}x) = 1_M(g^{-1}x)f(x) = 0$, too. Thus $\widetilde{f}(x) = 0 = g\widetilde{f}(x)$ for any $x \in X \setminus M$. Conversely if $x \in M$ then $1_M(x) = 1 = 1_M(g^{-1}x)$ which yields $g\widetilde{f}(x) = \widetilde{f}(g^{-1}x) = 1_M(g^{-1}x)f(g^{-1}x) = f(g^{-1}x) = (gf)(x) = f(x) = 1_M(x)f(x) = \widetilde{f}(x)$ as $x \in M$. Altogether we have proved $\widetilde{f} = g\widetilde{f}$, (for any $x \in X$) which is the G-invariance of $\widetilde{f}$. And we have already seen that $\widetilde{f}(x) = f(x)$ for any $x \in M$. But we have also seen, that $\widetilde{f} + \mathbb{I}(M) = f + \mathbb{I}(M)$, which means nothing but $\widetilde{f} + \mathbb{I}(M)^G \mapsto f + \mathbb{I}(M)$ under the map in question. □

Proof of (9.8):
We will first prove that $G \times R[A] \to R[A]$ truly is a group action. To do this consider any g and $h \in\in G$ and any $f \in R[A]$. By definition we clearly have $ef = f$. And further we find

$$g(hf) \;=\; g\left(\sum_{\alpha\in A}(hf[\alpha])t^\alpha\right) \;=\; \sum_{\alpha\in A} g(hf[\alpha])t^\alpha \;=\; \sum_{\alpha\in A}(gh)f[\alpha]t^\alpha \;=\; (gh)f$$

From the homomorphism property of $R \to R : a \mapsto ga$ we find that $(g, f) \mapsto gf$ truly is an algebraic operation (we omit tedious computations). So it only remains to prove $R[A]^G = R^G[A]$. The inclusion " $\supseteq$ " is trivial. Conversely consider any $f \in R[A]^G$. Then we have to show that for any $\alpha \in A$ and any $g \in G$ we get $gf[\alpha] = f[\alpha]$. Yet to see this it suffices to compare coefficients

$$\sum_{\alpha\in A}(gf[\alpha])t^\alpha \;=\; gf \;=\; f \;=\; \sum_{\alpha\in A} f[\alpha]t^\alpha$$

Chapter 10

Homological Algebra

Consider a module M over a (not necessarily commutative) ring $(R, +, \cdot)$. To say that M is *finitely generated* means that there are finitely many elements m_1 to $m_n \in M$ such that any $x \in M$ can be written in the form $x = \sum_j b_j m_j$ for some $b_i \in R$. In other words iff the following homomorphism is surjective

$$\mu \ : \ R^n \twoheadrightarrow M \ : \ (b_1, \ldots, b_n) \mapsto \sum_{j=1}^{n} b_j m_j$$

In the language of chains of homomorphisms this can be put as: The chain $R^n \to M \to 0$ of module homomorphisms is exact. In order to have a more accurate description of M it would be nice to also know the kernel of μ.

In fact this is the question: 'Which $b \in R^n$ yield $\sum_j b_j m_j = 0$?' which amounts to a system of linear equations. We will concern ourselves in section 4.3 with solving these, but the best we can hope for is finding a parametrisation of $\ker(\mu)$. That is we want to have some base vectors k_1 to $k_m \in R^m$ such that $\mu(b) = 0$ if and only if $b = a_1 k_1 + \cdots + a_m k_m$ for some a_1 to $a_m \in R$. In turn $\ker(\mu)$ is the image of another homomorphism $\kappa : R^m \to R^n : (a_1, \ldots, a_m) \mapsto \sum_i a_i k_i$. In the language of chains of homomorphisms again, this is the exactness of

$$R^m \xrightarrow{\kappa} R^n \xrightarrow{\mu} M \to 0$$

A module M that allows such a chain is truly well-displayed, as the first isomorphism theorem of modules then allows to describe it, in the form

$$R^n \Big/ _{\mathrm{im}(\kappa)} \xrightarrow{\sim} M \ : \ b + \mathrm{im}(\kappa) \mapsto \sum_{j=1}^{n} b_j m_j$$

(10.1) Definition:
Let $(R, +, \cdot)$ be an arbitrary ring and M be an R-module. Then M is said to **admit a finite free presentation** (or simply to be **finitely presented**) iff there are integers m, $n \in \mathbb{N}$ such that there is an exact chain of module homomorphisms of the form

$$R^m \to R^n \to M \to 0$$

Chapter 11

Categorial Algebra

11.1 Categories

Generally speaking, algebra provides the structural concepts for all other fields of mathematics: Rings are the general concept of the base numbers, vector spaces are the general concept of function spaces and tangent spaces, algebras and derivations appear in calculus and so on. But you, the reader, probably noticed similarities, like homomorphisms have kernels or the existence of direct sums and products. Hence it makes sense to attempt a *second structurisation* that shall unify all these separate concepts in a general way. What we want to do here is introduce the concept of a *category*, that is a one-size-fits-all approach to all these different structures that allows to study their similarities in a general setting.

Hence we will define what we mean by a category and present the most fundamental examples of specific categories after that. The most prominent example is the category of sets - that is the entity of all sets. But it does not make sense to speak of the *set of sets*, say

$$\Omega \;:=\; \{\, X \mid X \text{ is a set} \,\}$$

This Ω is also called the **universe** in mathematics. However, if it was a set again, then we had $\Omega \in \Omega$ which not only is contra-intuitive (as we needed Ω to build up Ω in the first place), but can also lead to contradictions - the hell of mathematics. The solution is simple: We need a different name for arbitrary large collections of sets - let us call them *classes*.

In this chapter we will use the term *class* naively: A **class** is any collection of sets, with no restriction imposed on which or how many there are. As such a class need not be a set, any set is a class, but not every class is a set. A class that can also be build up as a set is said to be a **small** class. E.g. any set is a small class. A class that cannot be build up by set-theoretic constructions is called a **proper** class. E.g. the universe Ω above is a proper class.

You may think of a class as an expression of the form $\{\, X \mid \varphi(X) \,\}$ where $\varphi(X)$ is any expression of set theory concerning the variable symbol X. We have given a formal approach to classes, using the NBG axioms and a formal language with two variables (one for sets, the other for classes). And we have included a comment on alternative approaches to classes, at the end of this section, for the interested reader. But actually we recommend to use the term *class* naively, thinking of an arbitrary collection of sets, that might be too large to be a set itself.

(11.1) Definition:
A **category** is a triple $\mathcal{C} = (\mathcal{X}, \mathcal{M}, \circ)$ consisting of three classes $\mathcal{X}$, $\mathcal{M}$ and $\circ$ of the following form, that satisfy the properties (C1) and (C2) below:

- $\mathcal{X}$ is just any class, called the **objects** of the category $\mathcal{C}$ which we will also denote by $\mathrm{obj}(\mathcal{C}) := \mathcal{X}$. If $\mathcal{X}$ even is a set we say $\mathcal{C}$ is a **small** category, if $\mathcal{X}$ is a class but no set, we say that $\mathcal{C}$ is a **proper** category.

- $\mathcal{M}$ is a function of the form $\mathcal{M} : \mathcal{X}^2 \to \Omega$ that assigns every pair $(X, Y) \in \mathcal{X}^2$ of objects a set $\mathcal{M}(X, Y)$. The elements of $\mathcal{M}(X, Y)$ are called **morphisms** of $\mathcal{C}$ and we will also denote $\mathcal{C}(X, Y) := \mathcal{M}(X, Y)$. Lastly we will sometimes use the notation:

$$\mathrm{mor}(\mathcal{C}) \;:=\; \bigcup_{(X,Y)\in\mathcal{X}^2} \mathcal{M}(X, Y)$$

- For any triple $(X, Y, Z) \in \mathcal{X}^3$ of objects, there is a so-called **law of composition** $\circ_{X,Y,Z}$ of the morphisms. That is a map of the form

$$\mathcal{M}(X, Y) \times \mathcal{M}(Y, Z) \;\to\; \mathcal{M}(X, Z)$$

 If $\varphi \in \mathcal{M}(X, Y)$ and $\psi \in \mathcal{M}(Y, Z)$ are any morphisms of $\mathcal{C}$ we will write $\psi \circ \varphi$ as an abbreviation of $\circ_{X,Y,Z}(\varphi, \psi)$.

(C1) For any four objects U, X, Y and $Z \in \mathcal{X}$ and any morphisms $\varphi \in \mathcal{M}(U, X)$, $\psi \in \mathcal{M}(X, Y)$ and $\chi \in \mathcal{M}(Y, Z)$ we always have the following law of **associativity** of the composition

$$(\chi \circ \psi) \circ \varphi \;=\; \chi \circ (\psi \circ \varphi)$$

(C2) For any object $Y \in \mathcal{X}$ of $\mathcal{C}$ there is a morphism $\mathbb{1}_Y \in \mathcal{M}(Y, Y)$, called the **identity** on Y, that satisfies the following two properties:

$$\forall\, X \in \mathcal{X}\; \forall\, \varphi \in \mathcal{M}(X, Y) \;:\; \mathbb{1}_Y \circ \varphi \;=\; \varphi$$
$$\forall\, Z \in \mathcal{X}\; \forall\, \chi \in \mathcal{M}(Y, Z) \;:\; \chi \circ \mathbb{1}_Y \;=\; \chi$$

(11.2) Remark:
In any category $\mathcal{C}$, for any object $Y \in \mathrm{obj}(\mathcal{C})$ the identity morphism $\mathbb{1}_Y$ guaranteed by property (C2) already is uniquely determined.
Because if E_Y and $I_Y \in \mathcal{C}(Y, Y)$ both satisfy the properties of $\mathbb{1}_Y$ in (C2), then we could take $\varphi = I_Y$ and $\chi = E_Y$ to find $I_Y = \varphi = E_Y \circ \varphi = E_Y \circ I_Y$ and likewise $E_Y = \chi = \chi \circ I_Y = E_Y \circ I_Y$. Together this is $I_Y = E_Y \circ I_Y$ and $E_Y = E_Y \circ I_Y$ such that $E_Y = I_Y$.

(11.3) Remark:
In case of doubt let us append some comments on this: We can use almost any construction of sets for classes, too. If $\mathcal{X}$ and $\mathcal{Y}$ are classes and $X \in \mathcal{X}$ and $Y \in \mathcal{Y}$ are sets therein, then the ordered pair (X,Y) is a well-defined set again (namely $\{X,\{X,Y\}\}$). Therefore we can build up the *product* of the classes $\mathcal{X}$ and $\mathcal{Y}$, which is just another class

$$\mathcal{X} \times \mathcal{Y} \;:=\; \{\,(X,Y) \mid X \in \mathcal{X},\, Y \in \mathcal{Y}\,\}$$

A *relation* between $\mathcal{X}$ and $\mathcal{Y}$ is a subset (or more correctly a *subclass*) of $\mathcal{X} \times \mathcal{Y}$ and thereby a class in itself. A *function* $\mathcal{X} \to \mathcal{Y}$ is a relation between $\mathcal{X}$ and $\mathcal{Y}$ satisfying certain properties (totally defined and right-unique) and thereby a class again. This is how we can understand $\mathcal{M}$ as a class, that is a function from the product $\mathcal{X} \times \mathcal{X}$ to the universe Ω, in other words yet, a suitable subclass $\mathcal{M} \subseteq \mathcal{X} \times \mathcal{X} \times \Omega$. Even the law of composition $\circ$ is a function of the form $\circ : \mathcal{X}^3 \to \Omega$ in such a way that $\circ_{X,Y,Z} = \circ(X,Y,Z)$ is a function of the form

$$\circ_{X,Y,Z} \;\in\; \mathcal{F}\big(\mathcal{M}(X,Y) \times \mathcal{M}(Y,Z),\, \mathcal{M}(X,Z)\big)$$

As $\mathcal{M}(X,Y) \times \mathcal{M}(Y,Z)$ and $\mathcal{M}(X,Z)$ are sets there is a set of functions and $\circ_{X,Y,Z}$ is one of these – and hence $\circ_{X,Y,Z} \in \Omega$ a set again. So in fact all these constructions can be done with classes as well. There are some things to be aware of, however: As a function between classes $\mathcal{X} \to \mathcal{Y}$ is a class again, we *cannot* built up the class of all functions $\mathcal{F}(\mathcal{X},\mathcal{Y})$, as the elements need not be sets here! We will have to avoid this construction entirely.
In fact we cannot even build up an ordered pair $(\mathcal{X},\mathcal{Y})$ of classes, in the von Neumann way $\{\mathcal{X},\{\mathcal{X},\mathcal{Y}\}\}$, for the same reason: The elements need not be sets. But we only need to use this naively: That is two categories $\mathcal{C} = (\mathcal{X},\mathcal{M},\circ_{\mathcal{C}})$ and $\mathcal{D} = (\mathcal{Y},\mathcal{N},\circ_{\mathcal{D}})$ are considered *equal* $\mathcal{C} = \mathcal{D}$ if they share the same objects $\mathcal{X} = \mathcal{Y}$, for any two objects X, $Y \in \mathcal{X}$ they have the same morphisms $\mathcal{M}(X,Y) = \mathcal{N}(X,Y)$ and for any three objects X, Y, $Z \in \mathcal{X}$ and morphisms $\varphi \in \mathcal{M}(X,Y)$, $\psi \in \mathcal{M}(Y,Z)$ the respective compositions agree: $\psi \circ_{\mathcal{C}} \varphi = \psi \circ_{\mathcal{D}} \varphi$.

(11.4) Example:

(i) Our first example shall be the category **Set** of sets as this is where the terminology of categories comes from. The objects of this category simply are all the sets there are, that is $\mathrm{obj}(\mathbf{Set}) := \Omega$. Recall that the universe Ω is the class of all sets. Now for any two sets X and Y the morphisms of **Set** simply are all the functions from X to Y

$$\mathbf{Set}(X,Y) \;:=\; \mathcal{F}(X,Y)$$

Note that in case $X = \emptyset$ or $Y = \emptyset$ we also have $\mathcal{F}(X,Y) = \{\emptyset\}$, as $\emptyset$ is the only subset of $X \times Y$ and this trivially satisfies the properties of a function. The law of composition $\circ$ of **Set** is the usual composition of functions, that is if $f \in \mathbf{Set}(X,Y)$ and $g \in \mathbf{Set}(Y,Z)$ then $g \circ f \in \mathbf{Set}(X,Z)$ is the function defined by $g \circ f := gf$ which is $(g \circ f)(x) := g(f(x))$. The identity on the set Y is the identity map $\mathbb{1}_Y(y) = y$. In case $Y = \emptyset$ we have $\mathbb{1}_Y = \emptyset$ again.

($\diamondsuit$) Looking ahead we already note the following: In this category the epimorphisms are precisely the surjective maps, monomorphisms are precisely the injective maps and hence isomorphisms are precisely the bijective maps. The empty set $\emptyset$ is the one and only initial object of **Set**, whereas any set X with $\#X = 1$ is a terminal object.

(ii) As a next example let us introduce the category **Ring** of commutative rings. That is $\mathrm{obj}(\mathbf{Ring}) :=$ the class of all commutative rings $(R, +, \cdot)$. And for any two objects $\mathcal{R} = (R, +, \cdot)$ and $\mathcal{S} = (S, +, \cdot)$ the morphisms of **Ring** are just the usual homomorphisms of rings

$$\mathbf{Ring}(\mathcal{R}, \mathcal{S}) \;:=\; \mathrm{rhom}(R, S)$$

Note that $\mathcal{R}$ and $\mathcal{S}$ are triples of sets here and not classes, in contrast to our usual convention. Hence we will also write $\mathbf{Ring}(R, S)$ for the set of morphisms, as we did before, since the algebraic operations $+$ and $\cdot$ on R and S respectively, are understood. The law of composition $\circ$ of **Ring** is the usual composition of functions, that we used for **Set** already. And clearly $\mathbb{1}_R$ is an endomorphism of the ring $(R, +, \cdot)$ and hence we do have the identities required in (C2).

($\diamondsuit$) Looking ahead again we note: The notions of monomorphism, epimorphism and isomorphism in **Ring** coincide with the notions we introduced before. The zero-ring $R = 0$ is both, the initial and terminal object of **Ring**.

(iii) Another classic example is the category $\mathbf{Mod}_R$ of R-modules, over a fixed ring $(R, +, \cdot)$. That is $\mathrm{obj}(\mathbf{Mod}_R) :=$ the class of all modules $(M, +, \diamond)$ over the ring R and for any two R-modules $\mathcal{M} = (M, +, \diamond)$ and $\mathcal{N} = (N, +, \diamond)$ the morphisms are just the R-linear maps

$$\mathbf{Mod}_R(\mathcal{M}, \mathcal{N}) \;:=\; \mathrm{mhom}_R(M, N)$$

Again we will write $\mathbf{Mod}_R(M, N)$ in order to stay in conjunction with the notation used so far, which is not a problem, as the addition $+$ and scalar multiplication $\diamond$ on M and N are understood. The law of composition $\circ$ of $\mathbf{Mod}_R$ is the usual composition of functions, that we used for **Set** already. And clearly $\mathbb{1}_M$ is an endomorphism of the R-module $(M, +, \diamond)$ and hence we do have the identities required in (C2).

($\diamondsuit$) Looking ahead once more we note: The notions of monomorphism, epimorphism and isomorphism in $\mathbf{Mod}_R$ coincide with the notions we introduced before. The zero-module $M = 0$ is both, the initial and terminal object of $\mathbf{Mod}_R$.

(iv) If $(M, \circ)$ is a monoid with neutral element e, then this gives rise to a category $\mathcal{C}_M$ in the following way: $\mathcal{C}_M$ only has one object, say the set M itself: $\mathrm{obj}(\mathcal{C}_M) := \{M\}$. For the morphisms of $\mathcal{C}_M$ we just take the elements of M. As $\mathcal{C}_M$ has one object only, it suffices to define $\mathcal{C}_M(M, M) := M$. The composition of morphisms of $\mathcal{C}_M$ is the composition $\circ$ of elements of M. In particular the identity $\mathbb{1}_M = e$ is the neutral element of M.

And the converse is true, as well: If a category $\mathcal{C}$ has one object X only, then the morphisms $M := \mathcal{C}(X, X)$ form a monoid with $\mathbb{1}_X$ as neutral element under the composition $\circ$ of morphisms. And thereby $\mathcal{C}$ and $\mathcal{C}_M$ are much the same category, they only differ in the concrete object X or M they live on (this is to say: $(X \mapsto M,\ m \mapsto m)$ is an isofunctor).

(v) Another widely used category is that of topological spaces. Let us recall the definition of a **topological space** of section 6.1: This is an ordered pair $(X, \mathcal{T})$ consisting of a set X and a family of subsets $\mathcal{T} \subseteq \mathcal{P}(X)$. The sets $U \in \mathcal{T}$ are called the **open sets** of X and the collection $\mathcal{T}$ itself is said to be the **topology** on X. Hereby we demand, that $\emptyset$ and X are open sets and that finite intersections and arbitrary unions of open sets are open again. That is we require the following four properties of the topology $\mathcal{T}$:

(T1) $\emptyset \in \mathcal{T}$

(T2) $X \in \mathcal{T}$

(T3) $U, V \in \mathcal{T} \implies U \cap V \in \mathcal{T}$

(T4) $\mathcal{U} \subseteq \mathcal{T} \implies \bigcup \mathcal{U} \in \mathcal{T}$.

These are the objects of the category **Top** of topological spaces: Formally obj(**Top**) := the class of topological spaces $(X, \mathcal{T})$. If now $\mathcal{X} = (X, \mathcal{T}_X)$ and $\mathcal{Y} = (Y, \mathcal{T}_Y)$ are topological spaces then a function $f : X \to Y$ is said to be **continuous** if the preimage of an open set in Y is open in X, that is iff for any $V \in \mathcal{T}_Y$ we have $f^{-1}(V) \in \mathcal{T}_X$. The morphisms of **Top** are precisely the continuous functions in this sense

$$\mathbf{Top}(\mathcal{X}, \mathcal{Y}) \;:=\; \left\{ f : X \to Y \mid \forall\, V \in \mathcal{T}_Y \,:\, f^{-1}(V) \in \mathcal{T}_X \right\}$$

Hence we have $\mathbf{Top}(\mathcal{X}, \mathcal{Y}) \subseteq \mathcal{F}(X, Y)$ and can take the usual composition of maps, as in (i), as the law of composition $\circ$ for **Top**. Usually $\mathbf{Top}(\mathcal{X}, \mathcal{Y})$ is just denoted as $C(X, Y)$. Yet as this notation suppresses the topologies $\mathcal{T}_X$ and $\mathcal{T}_Y$ involved, it can only be used, when these are understood. Clearly $\mathbb{1}_Y^{-1}(V) = V$ such that the identity map on Y is continuous. As the associativity of $\circ$ is inherited from **Set** we find that **Top** indeed is a well-defined category.

($\diamondsuit$) Looking ahead, one more time, we find: The isomorphisms in **Top** are bijective, continuous maps. But as the inverse of a continuous map need not be continuous, this is not equivalent. The isomorphisms of this category are called **homeomorphisms** or **bicontinuous** maps. This is a bijective map $f \in C(X, Y)$ such that $f^{-1} \in C(Y, X)$ again. A counter-example is the following: Take $X_1 = X_2 = \{0, 1\}$ under the topologies $\mathcal{T}_1 := \mathcal{P}(X)$ and $\mathcal{T}_2 := \{\emptyset, X\}$. Then $\mathbb{1}_X : X_1 \to X_2$ is bijective and continuous, but its inverse $\mathbb{1}_X : X_2 \to X_1$ is not continuous.

(vi) Another neat application are **punctuated topological spaces**, these are triples $(X, \mathcal{T}, x_*)$ where $(X, \mathcal{T})$ is a topological space and $x_* \in X$ is a point. These are the objects of the category $\mathbf{Top}_*$ of punctuated topological spaces obj($\mathbf{Top}_*$) := the class of all punctuated topological spaces $(X, \mathcal{T}, x_*)$. A morphism f from $\mathcal{X} = (X, \mathcal{T}_X, x_*)$ to $(Y, \mathcal{T}_Y, y_*)$ is a continuous map, that respects the fixed point $f(x_*) = y_*$, that is

$$\mathbf{Top}_*(\mathcal{X}, \mathcal{Y}) \;:=\; \{ f \in \mathbf{Top}(\mathcal{X}, \mathcal{Y}) \mid f(x_*) = y_* \}$$

The law of composition $\circ$ once more is just the usual composition of maps and as $\mathbb{1}_Y(y_*) = y_*$ we also have the identity morphisms required for a category.

(vii) Let us return to our introductory example, the category of sets, and expand it a little: We want to introduce the category **Rel** of relations - though the name is not perfectly chosen, as it refers to the morphism not the objects. The objects are all the sets again, $\mathrm{obj}(\mathbf{Rel}) := \Omega$. But given any two sets X, Y the morphisms from X to Y are just the relations

$$\mathbf{Rel}(X,Y) \;:=\; \mathcal{P}\big(X \times Y\big)$$

If now $R \subseteq X \times Y$ and $S \subseteq Y \times Z$ are relations between X and Y resp. between Y and Z, then we define the composition of these $S \circ R = SR$ in the following way

$$SR \;:=\; \{\, (x,z) \in X \times Z \mid \exists\, y \in Y \,:\, (x,y) \in R \text{ and } (y,z) \in S \,\}$$

Note that in the usual notation this reads as: $xSRz$ if and only if xRy and ySz for some $y \in Y$. It is easy to see that this construction is associative and the identity $\mathbb{1}_Y$ on Y is given to be the diagonal (i.e. the identity function) $\mathbb{1}_Y = \{\, (y,y) \mid y \in Y \,\}$.

(viii) Our second last example will be a general construction: Given any category $\mathcal{C}$ we define the **opposite category** $\mathcal{C}^{\mathrm{op}}$ of $\mathcal{C}$ by keeping the objects, but reversing the direction of all morphisms. Formally $\mathcal{C}^{\mathrm{op}}$ is defined in the following way: The objects of $\mathcal{C}^{\mathrm{op}}$ are just the objects of $\mathcal{C}$ again

$$\mathrm{obj}\big(\mathcal{C}^{\mathrm{op}}\big) \;:=\; \mathrm{obj}(\mathcal{C})$$

Now for any two objects X, $Y \in \mathrm{obj}(\mathcal{C}^{\mathrm{op}})$ the morphisms from X to Y are just the morphisms of $\mathcal{C}$ from Y to X. Consequentially the law of composition of $\mathcal{C}^{\mathrm{op}}$ is just the law of composition of $\mathcal{C}$ reversed: If $f \in \mathcal{C}^{\mathrm{op}}(X,Y)$ and $g \in \mathcal{C}^{\mathrm{op}}(Y,Z)$ then

$$\mathcal{C}^{\mathrm{op}}(X,Y) \;:=\; \mathcal{C}(Y,X)$$

$$g \circ f \;:=\; f \circ_{\mathcal{C}} g \;\in\; \mathcal{C}^{\mathrm{op}}(X,Z)$$

Thereby the identity $\mathbb{1}_Y$ of $\mathcal{C}$ also is the identity on Y of $\mathcal{C}^{\mathrm{op}}$. ($\diamondsuit$) And looking ahead it is clear that monomorphisms and epimorphisms are interchanged by going from $\mathcal{C}$ to $\mathcal{C}^{\mathrm{op}}$. Isomorphisms are preserved, but initial and terminal objects are interchanged again.

(viii) ($\diamondsuit$) Our final example is a little more sophisticated - it is the underlying concept of differential and algebraic geometry - **spaces with** $\mathbb{F}$-valued **functions**, where $(\mathbb{F},+,\cdot)$ is a fixed field. Let us first define the objects of $\mathbf{Space}_{\mathbb{F}}$ this category: A space with functions is an ordered triple $(X,\mathcal{T},\mathcal{O})$ satisfying the following properties:

(S1) $(X,\mathcal{T})$ is a topological space.

(S2) $\mathcal{O}$ is a collection of $\mathbb{F}$-algebras $\mathcal{O}(U) \;\leq_{\mathrm{a}}\; \mathcal{F}(U,\mathbb{F})$ of $\mathbb{F}$-valued functions, where $U \in \mathcal{T}$ is an open subset of X. These are called the *regular functions* on X.

(S3) If U, $V \subseteq X$ are open subsets with $U \subseteq V$, then we require that for any regular function $s \in \mathcal{O}(V)$ the restriction $s\big|_U \in \mathcal{O}(U)$ is regular again.

(S4) If $U \subseteq X$ is open and $r \in \mathcal{O}(U)$ a regular function, then we require, that the non-zero locus $D(r) := \{\, x \in U \mid r(x) \neq 0 \,\} \subseteq X$ is open and that $1/r \in \mathcal{O}(D(r))$ is regular again.

(S5) If $\mathcal{U} \subseteq \mathcal{T}$ is a collection of open subsets of X and $V := \bigcup \mathcal{U} \subseteq X$ is their union, then for any $s \in \mathcal{F}(V, \mathbb{F})$ we require, that being regular is determined locally, in the sense that

$$\Big(\forall\, U \in \mathcal{U} \,:\, s\big|_U \in \mathcal{O}(U) \implies s \in \mathcal{O}(V) \Big)$$

Now consider two spaces with functions $(X, \mathcal{T}_X, \mathcal{O}_X)$ and $(Y, \mathcal{T}_Y, \mathcal{O}_Y)$ over the common field $\mathbb{F}$. Then a morphisms μ in this category is just a continuous map $\mu : X \to Y$ such that for any open subset $V \subseteq Y$ and any regular map $s \in \mathcal{O}_Y(V)$ the composition $s\mu : \mu^{-1}(V) \to \mathbb{F}$ is a regular map $s\mu \in \mathcal{O}_X(\mu^{-1}(V))$ again. Therefore a morphism $\mu : (X, \mathcal{T}_X, \mathcal{O}_X) \to (Y, \mathcal{T}_Y, \mathcal{O}_Y)$ always induces its *comorphism* $\mu^*(V)$ for every open subset $V \subseteq Y$, which is a homomorphism of $\mathbb{F}$-algebras

$$\mu^*(V) \;:\; \mathcal{O}_Y(V) \to \mathcal{O}_X(\mu^{-1}(V)) \;:\; s \mapsto s\mu$$

The composition of morphisms is the usual composition of functions, therefore associativity and the existence of an identity are granted. Altogether we have introduced another category $\mathbf{Space}_{\mathbb{F}}$, that encompasses affine varieties of algebraic geometry and manifolds of differential geometry.

(11.5) Example:
We can even model partially ordered sets in the language of category theory: Let $\mathcal{I}$ be any class and let $\leq$ have the properties of a partial order on $\mathcal{I}$. That is (1) $i \leq i$, (2) $i \leq j$ and $j \leq k$ implies $i \leq k$ and (3) $i \leq j$ and $j \leq i$ implies $i = j$ for any i, j and $k \in \mathcal{I}$. Then we define the corresponding **arrow category** $\mathcal{A}_\leq$ in the following way: The objects of $\mathcal{A}_\leq$ are $\mathrm{obj}(\mathcal{A}_\leq) := \mathcal{I}$. And for any two objects i, $j \in \mathcal{I}$ we define the sets of morphisms

$$\mathcal{A}_\leq(i,j) \;:=\; \begin{cases} \{0,1\} \text{ if } i \leq j \\ \{0\} \text{ if not} \end{cases}$$

That is $i \leq j$ is equivalent to $1 \in \mathcal{A}_\leq(i,j)$. This allows to reconstruct $\leq$ from its arrow category. The composition is quite simple, the morphisms are either 0 or $1 \in \mathbb{Z}$, then we define

$$\mathcal{A}_\leq(i,j) \times \mathcal{A}_\leq(j,k) \;\to\; \mathcal{A}_\leq(i,k) \;:\; (\alpha, \omega) \mapsto \alpha\omega$$

Clearly this is associative and turns $1 \in \mathcal{A}_\leq(i,i)$ into the identity $\mathbb{1}_i$. Nota this also is well-defined: We get $\alpha\omega = 1$ if and only if $\alpha = 1$ and $\omega = 1$. But this implies $i \leq j$ and $j \leq k$. Thus we have $i \leq k$ by transitivity and hence $1 \in \mathcal{A}_\leq(i,k)$. ($\diamondsuit$) Some authors like to install an order in a category $\mathcal{C}$ by prescribing a functor from an arrow-category to $\mathcal{C}$, but we see no benefit in this abstraction.

(11.6) Remark:
Most of the examples above have been *concrete categories*, meaning the objects are sets with some additional structure (e.g. X in a topological space $\mathcal{X} = (X, \mathcal{T})$), the morphisms $\mathcal{C}(\mathcal{X}, \mathcal{Y}) \subseteq \mathcal{F}(X, Y)$ are certain functions on the underlying sets (e.g. $f : X \to Y$ between the topological spaces $\mathcal{X} = (X, \mathcal{T}_X)$ and $\mathcal{Y} = (Y, \mathcal{T}_Y)$) and the law of composition $\circ$ is just the usual composition of functions. This is commonplace, but later on we will regard chain complexes as objects where the morphisms will not only be simple functions.

(11.7) Definition:
If $\mathcal{B}$ and $\mathcal{C}$ are categories, then $\mathcal{B}$ is said to be a **subcategory** of $\mathcal{C}$ - written as $\mathcal{B} \leq \mathcal{C}$ - iff we have the following three properties

(1) $\text{obj}(\mathcal{B}) \subseteq \text{obj}(\mathcal{C})$

(2) For any objects X, $Y \in \text{obj}(\mathcal{B})$ we have $\mathcal{B}(X,Y) \subseteq \mathcal{C}(X,Y)$. If we even have $\mathcal{B}(X,Y) = \mathcal{C}(X,Y)$, then $\mathcal{B}$ is said to be a **full** subcategory of $\mathcal{C}$.

(3) For any objects X, Y, $Z \in \text{obj}(\mathcal{B})$ and any morphisms $\varphi \in \mathcal{B}(X,Y)$ and $\psi \in \mathcal{B}(Y,Z)$ the laws of composition agree

$$\psi \circ_{\mathcal{B}} \varphi \quad = \quad \psi \circ_{\mathcal{C}} \varphi$$

(11.8) Remark:
It is clear, that we get a subcategory $\mathcal{B}$ of $\mathcal{C}$, if we begin with a subclass $\mathcal{X} \subseteq \text{obj}(\mathcal{C})$ and for any X, $Y \in \mathcal{X}$ take a subset $\mathcal{M}(X,Y) \subseteq \mathcal{C}(X,Y)$ such that (1) for any $Y \in \mathcal{X}$ we have $\mathbb{1}_Y \in \mathcal{M}(Y,Y)$ and (2) for any X, Y, $Z \in \mathcal{X}$ and any $\varphi \in \mathcal{M}(X,Y)$ and $\psi \in \mathcal{M}(Y,Z)$ we have $\psi \circ \varphi \in \mathcal{M}(X,Z)$. Then $\mathcal{B} = (\mathcal{X}, \mathcal{M}, \circ)$ is a subcategory of $\mathcal{C}$, where the law of composition $\circ$ is inherited by restriction from $\mathcal{C}$. Also it is clear, that the relation $\leq$ of being a subcategory has the properties of a partial order, that is (1) $\mathcal{C} \leq \mathcal{C}$, (2) $\mathcal{C} \leq \mathcal{D}$ and $\mathcal{D} \leq \mathcal{C}$ together imply $\mathcal{C} = \mathcal{D}$ and (3) $\mathcal{B} \leq \mathcal{C}$ and $\mathcal{C} \leq \mathcal{D}$ together imply $\mathcal{B} \leq \mathcal{C}$.

(11.9) Example:

- The category of finite sets is a full subcategory of the category **Set** of sets. Likewise we get a full subcategory **Dom** of integral domains of the category **Ring** of commutative rings. All we need to do is fix the objects $\text{obj}(\mathbf{Dom}) :=$ the class of commutative rings $(R, +, \cdot)$, that are integral domains. The morphisms are the ring-homomorphisms and the law of composition $\circ$ is the usual composition of maps, as in **Ring**.

- The category **Set** is a subcategory of **Rel** that share the same objects $\text{obj}(\mathbf{Set}) = \text{obj}(\mathbf{Rel})$, but in which **Set** has fewer morphisms, than **Rel**. So **Set** is far from being a full subcategory.

- A third example of this sort: A topological space $(X, \mathcal{T})$ is said to be a T_1-space, iff for any x, $y \in X$ with $x \neq y$ there are open sets U, $V \in \mathcal{T}$ such that $x \in U \setminus V$ and $y \in V \setminus U$. Let us define the full subcategory $\mathbf{Top}_1$ of **Top** by taking $\text{obj}(\mathbf{Top}_1) :=$ the class of all topological spaces $(X, \mathcal{T})$ that satisfy the T_1-property. The morphisms are the continuous functions again and the law of composition is the usual composition of maps, as in **Top**.

- The category $\mathbf{Top}_*$ of punctuated topological spaces is *not* a subcategory of the category **Top** of topological spaces, as the objects of $\mathbf{Top}_*$ differ from those of **Top** (they also contain a fixed point). Of course we can embed $\mathbf{Top}_*$ into **Top** by forgetting about the point, but this will require the notion of functors, that will be the topic of the next section. We will return to this.

(11.10) Definition: (viz. 1321)
Consider any category $\mathcal{C}$ and any two objects $X, Y \in \mathrm{obj}(\mathcal{C})$ therein. If now $\varphi \in \mathcal{C}(X,Y)$ is a morphism, then (inspired by the respective notions for rings, modules, etc.) we define the following notions:

(i) The morphism φ is said to be a **monomorphism**, iff for any object $T \in \mathrm{obj}(\mathcal{C})$ we find that the composition from the left $\varphi_* : \mathcal{C}(T,X) \hookrightarrow \mathcal{C}(T,Y) : \tau \mapsto \varphi \circ \tau$ is injective. That is for any two morphisms $\tau, \tau' \in \mathcal{C}(T,X)$ we have that $\varphi \circ \tau = \varphi \circ \tau'$ implies $\tau = \tau'$.

(ii) The morphism φ is said to be a **split-monomorphism**, iff φ admits a *left-inverse* $\overline{\varphi} \in \mathcal{C}(Y,X)$. And this is equivalent to saying that the composition with φ from the right always is surjectve:

(a) There is another morphism $\overline{\varphi} \in \mathcal{C}(Y,X)$ satisfying $\overline{\varphi} \circ \varphi = \mathbb{1}_X$

(b) For any object $T \in \mathrm{obj}(\mathcal{C})$ we find that $\varphi^* : \mathcal{C}(Y,T) \twoheadrightarrow \mathcal{C}(X,T) : \tau \mapsto \tau \circ \varphi$ is surjective

(iii) The morphism φ is said to be an **epimorphism**, iff for any object $T \in \mathrm{obj}(\mathcal{C})$ we find that the composition from the right $\varphi^* : \mathcal{C}(Y,T) \hookrightarrow \mathcal{C}(X,T) : \tau \mapsto \tau \circ \varphi$ is injective. That is for any two morphisms $\tau, \tau' \in \mathcal{C}(Y,T)$ we have that $\tau \circ \varphi = \tau' \circ \varphi$ implies $\tau = \tau'$.

(iv) The morphism φ is said to be a **split-epimorphism**, iff φ admits a *right-inverse* $\overline{\varphi} \in \mathcal{C}(Y,X)$. And this is equivalent to saying that the composition with φ from the left always is surjectve:

(a) There is another morphism $\overline{\varphi} \in \mathcal{C}(Y,X)$ satisfying $\varphi \circ \overline{\varphi} = \mathbb{1}_Y$

(b) For any object $T \in \mathrm{obj}(\mathcal{C})$ we find that $\varphi_* : \mathcal{C}(T,X) \twoheadrightarrow \mathcal{C}(T,Y) : \tau \mapsto \varphi \circ \tau$ is surjective

(v) The morphism φ is said to be an **isomorphism**, iff it satisfies one (and hence all) of the following six equivalent properties (and in this case $\psi = \psi_X = \psi_Y$)

(a) φ is both, a split-monomorphism and an epimorphism

(b) φ is both, a monomorphism and a split-epimorphism

(c) There are some $\psi_X, \psi_Y \in \mathcal{C}(Y,X)$ such that $\psi_X \circ \varphi = \mathbb{1}_X$ and $\varphi \circ \psi_Y = \mathbb{1}_Y$

(d) There is a uniquely determined $\psi \in \mathcal{C}(Y,X)$ such that $\psi \circ \varphi = \mathbb{1}_X$ and $\varphi \circ \psi = \mathbb{1}_Y$

(e) For any object $T \in \mathrm{obj}(\mathcal{C})$ we find that $\varphi^* : \mathcal{C}(Y,T) \to \mathcal{C}(X,T) : \tau \mapsto \tau \circ \varphi$ is bijective

(f) For any object $T \in \mathrm{obj}(\mathcal{C})$ we find that $\varphi_* : \mathcal{C}(T,X) \to \mathcal{C}(T,Y) : \tau \mapsto \varphi \circ \tau$ is bijective

The uniquely determined ψ in property (d) is then called the **inverse** of φ, written as $\varphi^{-1} := \psi$. And we say the objects X and Y are **isomorphic**, iff there is an isomorphism $\psi \in \mathcal{C}(X,Y)$. We denote this by writing

$$X \cong Y \quad :\Longleftrightarrow \quad \exists\, \varphi \in \mathcal{C}(X,Y) \,:\, (d)$$

(vi) A morphism $\varphi \in \mathcal{C}(X,Y)$ where $X = Y$ is said to be an **endomorphism** of $X \in \mathrm{obj}(\mathcal{C})$ and an endomorphism, that also is an isomorphism is said to be an **automorphism** of $X \in \mathrm{obj}(\mathcal{C})$.

(vii) A category $\mathcal{C}$ is said to be **faithful**, iff it is a concrete category (i.e. the sets of morphisms $\mathcal{C}(X,Y)$ are subsets of the set of functions from X to Y) and any bijective morphism already is an isomorphism.

(11.11) Proposition: (viz. 1322)
Let $\mathcal{C}$ is a category X, Y and $Z \in \mathrm{obj}(\mathcal{C})$ are objects and $\Phi \in \mathcal{C}(X,Y)$ and $\Psi \in \mathcal{C}(Y,Z)$ be isomorphisms, then $\Psi \circ \Phi \in \mathcal{C}(X,Z)$ is an isomorphism, as well with inverse

$$\big(\Psi \circ \Phi\big)^{-1} \;=\; \Phi^{-1} \circ \Psi^{-1}$$

Thereby the relation $\cong$ of isomorphy on the objects of $\mathcal{C}$ has the properties of an equivalence relation, that is for any X, Y and $Z \in \mathrm{obj}(\mathcal{C})$ we get

(1) $X \cong X$

(2) if $X \cong Y$ then $Y \cong X$, as well

(3) if $X \cong Y$ and $Y \cong Z$, then $X \cong Z$, as well

(11.12) Definition:
Let $\mathcal{C}$ be any category, then an object $U \in \mathrm{obj}(\mathcal{C})$ is said to be **universal** or **initial**, iff for any other object $X \in \mathrm{obj}(\mathcal{C})$ there is a uniquely determined morphism φ from U to X. Formally iff

$$\forall\ X \in \mathrm{obj}(\mathcal{C}) \;:\; \exists!\ \varphi \in \mathcal{C}(U,X)$$

The dual notion is the following: An object $T \in \mathrm{obj}(\mathcal{C})$ is said to be **final** or **terminal**, iff for any other object $X \in \mathrm{obj}(\mathcal{C})$ there is a uniquely determined morphism φ from X to T. Formally again

$$\forall\ X \in \mathrm{obj}(\mathcal{C}) \;:\; \exists!\ \varphi \in \mathcal{C}(X,T)$$

(11.13) Lemma: (viz. 1322)
If $\mathcal{C}$ is an arbitrary category, than any two universal objects U and $V \in \mathrm{obj}(\mathcal{C})$ are isomorphic $U \cong V$. Likewise any two terminal objects S and $T \in \mathrm{obj}(\mathcal{C})$ are isomorphic $S \cong T$.

(11.14) Proposition: (viz. 1322)
Let $\mathcal{C}$ be any category and fix any objects X, Y and $Z \in \mathrm{obj}(\mathcal{C})$. Also consider the morphisms $\varphi \in \mathcal{C}(X,Y)$ and $\psi \in \mathcal{C}(Y,Z)$. Then the monomorphisms and epimorphisms of $\mathcal{C}$ satisfy the following properties:

(i) If $\mathcal{C}$ is a concrete category (that is for any objects X, Y of $\mathcal{C}$ the morphisms $\varphi \in \mathcal{C}(X,Y)$ are functions $\varphi : X \to Y$ and the composition of morphisms is the usual composition of functions), then we get: If φ is an injective morphism, then φ is a monomorphism. And if φ is a surjective morphism, then φ is an epimorphism.

(ii) Any split-monomorphism already is a monomorphism. Likewise any split-epimorphism already is an epimorphism. (The converse need not be true, in general).

(iii) If both φ and ψ are monomorphisms. Then $\psi \circ \varphi \in \mathcal{C}(X,Z)$ is a momomorphism, as well. Conversely: If $\psi \circ \varphi$ is a monomorphisms, then φ has to be a monomorphism, too.

(iv) If both φ and ψ are epimorphisms. Then $\psi \circ \varphi \in \mathcal{C}(X,Z)$ is an epimorphism, as well. Conversely: If $\psi \circ \varphi$ is an epimorphisms, then ψ has to be an epimorphism, too.

(v) Monomorphisms to initial objects are isomorphisms, that is: If Y is an initial object of $\mathcal{C}$ and φ is a monomorphism, then φ already is an isomorphism.

(vi) Epimorphisms from terminal objects are isomorphisms, that is: If Y is a terminal object of $\mathcal{C}$ and ψ is an epimorphism, then ψ already is an isomorphism.

(11.15) Example: (viz. 1323)

(i) In the category **Set** of sets, for any function $f : X \to Y$, the following are equivalent: (a) f is injective, (b) f is a split-monomorphism and (c) f is a monomorphism. Likewise (a) f is surjective, (b) is a split-epimorphism and f is an epimorphism.

(ii) Let us regard the the category $\mathbf{Mod}_R$ of R-modules over a (not necessarily commutative) ring $(R, +, \cdot)$. In this category we find the following equivalences for any objects (i.e. R-modules) M and N and any R-module homomorphism $\varphi : M \to N$:

$$\begin{aligned} \varphi \text{ is a monomorphism} &\iff \varphi \text{ is an injective morphism} \\ \varphi \text{ is an epimorphism} &\iff \varphi \text{ is a surjective morphism} \\ \varphi \text{ is an isomorphism} &\iff \varphi \text{ is a bijective morphism} \end{aligned}$$

(iii) Let us regard the the category **Ring** of rings. In this category we find the following equivalences for any objects (i.e. rings) R and S and any homomorphism $\varphi : R \to S$ of rings:

$$\begin{aligned} \varphi \text{ is a monomorphism} &\iff \varphi \text{ is an injective morphism} \\ \varphi \text{ is an isomorphism} &\iff \varphi \text{ is a bijective morphism} \end{aligned}$$

And clearly any surjective homomorphism of rings is an epimorphism in **Ring**. Yet $\zeta : \mathbb{Z} \to \mathbb{Q}$ defined by $\zeta(k) = k/1$ is an example of an epimorphism in the category **Ring**, that is not a surjective map.

(iv) The equivalences for morphisms in (ii) also hold true in the category **Set** of sets and the category **Group** of groups. And the equivalences in (iii) also hold true in the category $\mathbf{Alg}_R$ of R-algebras over a commutative ring $(R, +, \cdot)$.

(11.16) Definition:
Consider any category $\mathcal{C}$ and some objects X, Y and $Z \in \mathrm{obj}(\mathcal{C})$. If now $\varphi \in \mathcal{C}(Y, Z)$ and $\psi \in \mathcal{C}(X, Z)$ are morphisms with the same target Z, then we say that ψ **factors through** φ, written as $\varphi \mid \psi$, iff

$$\varphi \mid \psi \quad :\iff \quad \exists\, \varphi' \in \mathcal{C}(X, Y) \,:\, \psi = \varphi \circ \varphi'$$

Now for any two morphisms $\psi_1 \in \mathcal{C}(X_1, Z)$ and $\psi_2 \in \mathcal{C}(X_2, Z)$ with the same target Z, but arbitrary domains X_1, $X_2 \in \mathrm{obj}(\mathcal{C})$, we define the relation of **bimorphism equivalence** by

$$\begin{aligned} \psi_1 \sim \psi_2 \quad &:\iff \quad \psi_1 \mid \psi_2 \text{ and } \psi_2 \mid \psi_1 \\ &\iff \quad \exists\, \psi_1' \in \mathcal{C}(X_2, X_1) \text{ and } \exists\, \psi_2' \in \mathcal{C}(X_1, X_2) \,:\, \psi_2 = \psi_1 \circ \psi_1' \text{ and } \psi_1 = \psi_2 \circ \psi_2' \end{aligned}$$

(11.17) Proposition: (viz. 1326)
If $\mathcal{C}$ is any category $Z \in \mathrm{obj}(\mathcal{C})$ is any object, then the bimorphism relation $\sim$ acts as an equivalence relation on the class of all morphisms of $\mathcal{C}$ with target Z. That is: Given any morphisms $\psi_k \in \mathcal{C}(X_k, Z)$ where $X_k \in \mathrm{obj}(\mathcal{C})$ and $k \in 1 \ldots 3$ we get the properties

(1) $\psi_1 \sim \psi_1$

(2) $\psi_1 \sim \psi_2 \implies \psi_2 \sim \psi_1$

(3) $\psi_1 \sim \psi_2$ and $\psi_2 \sim \psi_2 \implies \psi_1 \sim \psi_3$

Now suppose ψ_1 and ψ_2 are monomorphisms, with $\psi_1 \sim \psi_2$. Then the morphisms ψ_1' and ψ_2' satisfying $\psi_2 = \psi_1 \circ \psi_1'$ and $\psi_1 = \psi_2 \circ \psi_2'$ are uniquely determined and mutually inverse $\psi_2' = (\psi_1')^{-1}$.

(11.18) Definition:
Consider a category $\mathcal{C} = (\mathcal{X}, \mathcal{M}, \circ)$ such that for any pair of objects $X, Y \in \mathrm{obj}(\mathcal{C}) = \mathcal{X}$ the morphisms carry the structure of a commutative group

$$\mathcal{A}(X,Y) \;=\; \big(\mathcal{C}(X,Y), +\big)$$

Note that the operations $+$ actually depend on (X,Y), but by abuse of notation we denote all by the same symbol. Likewise we denote the neutral element of $\mathcal{C}(X,Y)$ by 0 instead of $0_{X,Y}$ though it also depends on (X,Y). Let $\mathcal{A}$ be the assignment $(X,Y) \mapsto \mathcal{A}(X,Y)$, then the triple $(\mathcal{X}, \mathcal{A}, \circ)$ is said to be an **additive category**, iff for any objects X, Y, $Z \in \mathrm{obj}(\mathcal{C})$ and any morphisms φ, φ_1, $\varphi_2 \in \mathcal{C}(X,Y)$ and ψ, ψ_1, $\psi_2 \in \mathcal{C}(Y,Z)$ we get

$$\begin{aligned} \big(\psi_1 + \psi_2\big) \circ \varphi &= \big(\psi_1 \circ \varphi\big) + \big(\psi_2 \circ \varphi\big) \\ \psi \circ \big(\varphi_1 + \varphi_2\big) &= \big(\psi \circ \varphi_1\big) + \big(\psi \circ \varphi_2\big) \end{aligned}$$

Being a little sloppy we usually say that in this case $\mathcal{C}$ is an additive category itself, if the operations $+$ on the morphisms $\mathcal{C}(X,Y)$ are understood. Also we introduce the convention that the law of composition $\circ$ binds stronger than the addition $+$, that is we would write $\psi_1 \circ \varphi + \psi_2 \circ \varphi$ as an abbreviation of $(\psi_1 \circ \varphi) + (\psi_2 \circ \varphi)$ and likewise $\psi \circ \varphi_1 + \psi \circ \varphi_2$ for $(\psi \circ \varphi_1) + (\psi \circ \varphi_2)$.

(11.19) Example:

- The most prominent examples of additive categories are **Ring** and $\mathbf{Mod}_R$. Of course the additions $+$ on the morphisms are point-wise

$$\big(\varphi + \psi\big)(x) \;=\; \varphi(x) + \psi(x)$$

- A truly new example is the following: Let $(R, +, \cdot)$ be a commutative ring, this gives rise to a small category $\mathcal{R}$ with one object only: $\mathrm{obj}(\mathcal{R}) := \{R\}$. The morphisms are the multiplication functions:

$$\mathcal{R}(R,R) \;:=\; \{\, \lambda_a : u \mapsto au \mid a \in R \,\}$$

Then it is clear that $\mathcal{R}(R,R)$ carries an additive structure under the point-wise addition $\lambda_a + \lambda_b : u \mapsto (a+b)u$. It is also clear that $\lambda_0 = 0$ is the neutral element of this group and that $\lambda_1 = \mathbb{1}_R$ is the identity. Thus $\mathcal{R}$ is an additive category.

(11.20) Proposition: (viz. 1327)
Let $\mathcal{C}$ be an additive category, X, Y, $Z \in \mathrm{obj}(\mathcal{C})$ be objects and $\varphi \in \mathcal{C}(X,Y)$, $\psi \in \mathcal{C}(Y,Z)$ be morphisms of $\mathcal{C}$. Then we get the following identities:

$$\begin{aligned} \psi \circ 0 &= 0 \\ 0 \circ \varphi &= 0 \\ \varphi \circ (-\varphi) &= -(\psi \circ \varphi) \\ (-\psi) \circ \varphi &= -(\psi \circ \varphi) \end{aligned}$$

(11.21) Remark: $(\diamondsuit)$

- As promised let us present three separate ways how to formalize classes: The most direct approach is to use a two-sorted language, one sort for sets and the other sort for classes. This idea was pursued by Bernays and also is the way in which we presented the NBG-axioms in section 0.6. We will write sets by straight latin letters X, Y, ... and classes by script letters $\mathcal{X}$, $\mathcal{Y}$, ... There are two *element of* relations, one between sets $x \in X$ and the other between sets and classes $X \in \mathcal{X}$. Yet there is *no element of* relation between classes themselves. That is $\mathcal{X} \in \mathcal{Y}$ is an *illegal expression*! Then the NBG-axioms provide a set of rules how to handle sets and classes.

- There also is another approach introduced by Gödel, refined by Mendelson, that uses a one-sorted language only: All variable symbols stand for classes, but we introduce a predicate M that says 'the class X is a set': $M(X) := \exists\, \mathcal{X}\, (X \in \mathcal{X})$. Thereby M comes from the german word *menge* for set. The negation thereof $P(X) := \forall\, \mathcal{X}\, \neg(X \in \mathcal{X})$ then is 'X is a proper class'. The formula 'For any set X we have $\varphi(X)$' of Bernays can then be translated into $\forall\, X\, (M(X) \implies \varphi(X))$ and likewise 'There is a set X with $\varphi(X)$' can be translated into $\exists\, X\, (M(X) \wedge \varphi(X))$'. Under this translation these two approaches yield the same results.

- The third approach is to say a class is an expression of the form $\mathcal{X} = \{\, X \mid \varphi(X) \,\}$, where φ is any formula in the language of sets. E.g. the universe then is $\Omega = \{\, X \mid X = X \,\}$. And if X_0 is a fixed set (a constant symbol in an extension of the language) then X_0 also is a class in the form $X_0 = \{\, X \mid X = X_0 \,\}$. This is what we recommend for a naive understanding, but be aware, that this is not a real answer, since it is not founded on formal logic.

11.2 Functors

In the previous section we have studied categories, in a manner of speaking, these are the objects of category theory. The reason why category has been developed is to study the interplay between different categories. This is where functors arise - in this sense, functors are the morphisms between categories. The most prominent functor is the spec-functor, that turns a commutative ring into a topological space. To study functors is to study the relations between categories.

(11.22) Definition:
Suppose $\mathcal{C}$ and $\mathcal{D}$ are categories, then the ordered pair $F = (F_o, F_m)$ is said to be a **covariant functor** from $\mathcal{C}$ to $\mathcal{D}$, written as $F : \mathcal{C} \to \mathcal{D}$, iff $F_o : \mathrm{obj}(\mathcal{C}) \to \mathrm{obj}(\mathcal{D})$ is a function (of classes). For ease of notation we write $F(X) := F_o(X) \in \mathrm{obj}(\mathcal{D})$ for any object $X \in \mathcal{C}$. Also F_m is a class of functions that assigns any two objects $X, Y \in \mathrm{obj}(\mathcal{C})$ a function of the form

$$F_m(X,Y) \ : \ \mathcal{C}(X,Y) \to \mathcal{D}(F(X),F(Y))$$

By slight abuse of notation we will write $F(\varphi) := F_m(X,Y)(\varphi) \in \mathcal{D}(F(X),F(Y))$ for any morphism $\varphi \in \mathcal{C}(X,Y)$. Thereby, for any objects $X, Y, Z \in \mathrm{obj}(\mathcal{C})$ and any morphisms $\varphi \in \mathcal{C}(X,Y)$ and $\psi \in \mathcal{C}(Y,Z)$ we require the following identity:

$$F\big(\psi \circ_{\mathcal{C}} \varphi\big) \ = \ F(\psi) \circ_{\mathcal{D}} F(\varphi)$$

A **contra-variant functor** from $\mathcal{C}$ to $\mathcal{D}$, also written as $F : \mathcal{C} \to \mathcal{D}$, is much the same: F_o is just the same, as in the covariant case above, but for any two objects $F_m(X,Y)$ is a function of the form

$$F_m(X,Y) \ : \ \mathcal{C}(X,Y) \to \mathcal{D}(F(Y),F(X))$$

such that for any objects $X, Y, Z \in \mathrm{obj}(\mathcal{C})$ and any morphisms $\varphi \in \mathcal{C}(X,Y)$ and $\psi \in \mathcal{C}(Y,Z)$ we require the following identity:

$$F\big(\psi \circ_{\mathcal{C}} \varphi\big) \ = \ F(\varphi) \circ_{\mathcal{D}} F(\psi)$$

If $\mathcal{C}$ and $\mathcal{D}$ even are additive categories, then a (co- or contra- variant) functor $F : \mathcal{C} \to \mathcal{D}$ is said to be **additive**, iff for any two objects $X, Y \in \mathrm{obj}(\mathcal{C})$ and any two morphisms $\varphi_1, \varphi_2 \in \mathcal{C}(X,Y)$ we get

$$F\big(\varphi_1 + \varphi_2\big) \ = \ F(\varphi_1) + F(\varphi_2)$$

(11.23) Remark:

- Clearly, the notion of a contra-variant functor $F : \mathcal{C} \to \mathcal{D}$ is nothing but a covariant functor $F : \mathcal{C} \to \mathcal{D}^{\mathrm{op}}$ to the opposite category of $\mathcal{D}$.
- If $F : \mathcal{C} \to \mathcal{D}$ and $G : \mathcal{C} \to \mathcal{E}$ are functors of any kind, then we may define the composition $GF : \mathcal{C} \to \mathcal{E}$ by $GF(X) := G(F(X))$ and $GF(\varphi) := G(F(\varphi))$. The composition GF thereby is a functor again - covariant, if F and G are of the same kind and contra-variant, if F and G are of different types.

- Any category $\mathcal{C}$ has its **identity functor** $\mathbb{1}_{\mathcal{C}} : \mathcal{C} \to \mathcal{C}$, which is defined in the obvious way: For any object $X \in \mathrm{obj}(\mathcal{C})$ we let $\mathbb{1}_{\mathcal{C}}(X) := X$ and likewise for any morphism $\varphi \in \mathcal{C}(X,Y)$ we let $\mathbb{1}_{\mathcal{C}}(\varphi) := \varphi$. Then we get $\mathbb{1}_{\mathcal{C}} E = E$ for any category $\mathcal{B}$ and any functor $E : \mathcal{B} \to \mathcal{C}$ and $F\mathbb{1}_{\mathcal{C}} = F$ for any category $\mathcal{D}$ and any functor $F : \mathcal{C} \to \mathcal{D}$.

- If $F : \mathcal{C} \to \mathcal{D}$ is an additive functor between additive categories, then it is clear that $F(0) = 0$ and $F(-\varphi) = -F(\varphi)$ and hence $F(\psi - \varphi) = F(\psi) - F(\varphi)$ for any morphisms $\varphi, \psi \in \mathrm{mor}(\mathcal{C})$.

 The first identity is true, since $F(0) = F(0+0) = F(0) + F(0)$ and subtracting $F(0)$ we find $0 = F(0)$. The second equation follows immediately, as $0 = F(0) = F(\varphi - \varphi) = F(\varphi) + F(-\varphi)$ and subtracting $F(\varphi)$ this is $-F(\varphi) = F(-\varphi)$.

(11.24) Example:

- Our first, trivial example of a functor is the so-called *forgetful functor*. This can be defined for any concrete category, but we want to do it exemplarily for the category **Top** of topological spaces here. In general the forgetful functor strips the additional structure of the objects, picking out the base set and takes the morphisms as the functions they are. In the case of **Top** it reads as

$$\begin{array}{rcl} \mathbf{Top} & \to & \mathbf{Set} \\ (X,\mathcal{T}) & \mapsto & X \\ f & \mapsto & f \end{array}$$

- Now if $(R,+,\cdot)$ is a fixed commutative ring and $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ is a fixed ideal of R, recall the definition of the sub-module $\mathfrak{a}M$ of M

$$\mathfrak{a}M \;:=\; \left\{ \sum_{i=1}^{n} a_i x_i \;\middle|\; 1 \leq n \in \mathbb{N},\ a_i \in \mathfrak{a},\ x_i \in M \right\}$$

 As we have seen in (3.40.(vi)) the quotient module $M/\mathfrak{a}M$ is a well-defined $(R/\mathfrak{a})$-module under the scalar multiplication $(a+\mathfrak{a})(x+\mathfrak{a}M) := (ax)+\mathfrak{a}M$. Also if $\varphi : M \to N$ is an R-linear map, then we obtain a well-defined, $(R/\mathfrak{a})$-linear map $\varphi/\mathfrak{a} : M/\mathfrak{a}M \to N/\mathfrak{a}N$ by letting $(\varphi/\mathfrak{a})(x+\mathfrak{a}M) := \varphi(x)+\mathfrak{a}N$, according to (3.40.(vii)). It is clear that the operation $/\mathfrak{a}$ respects the composition of functions and hence we have an additive, covariant functor, given by

$$\begin{array}{rcl} \mathbf{Mod}_R & \to & \mathbf{Mod}_{R/\mathfrak{a}} \\ M & \mapsto & M\big/_{\mathfrak{a}M} \\ \varphi & \mapsto & \varphi\big/_{\mathfrak{a}} \end{array}$$

- Likewise if $(R,+,\cdot)$ is a fixed commutative ring and $U \subseteq R$ is a fixed, multiplicatively closed subset of R, we have defined the commutative ring $U^{-1}R$ in (2.116) and the module $U^{-1}M$ in (3.121). And if $\varphi : M \to N$ is an R-linear map, then by (3.125.(ii)) we obtain an $U^{-1}R$-linear map $U^{-1}\varphi : U^{-1}M \to U^{-1}N$ by letting $U^{-1}\varphi(x/u) := \varphi(x)/u$. Again it is clear, that the operation U^{-1} respects the composition of functions and hence we have another additive, covariant functor

$$\begin{aligned} \mathbf{Mod}_R &\to \mathbf{Mod}_{U^{-1}R} \\ M &\mapsto U^{-1}M \\ \varphi &\mapsto U^{-1}\varphi \end{aligned}$$

- An almost famous example if the **tensor functor**: Fix a commutative ring $(R, +, \cdot)$ and an R-module U then we get a covariant functor, by

$$\begin{aligned} \mathbf{Mod}_R &\to \mathbf{Mod}_R \\ M &\mapsto M \otimes U \\ \varphi &\mapsto \varphi \otimes \mathbb{1}_U \end{aligned}$$

 The construction of $M \otimes U$ and $\varphi \otimes \mathbb{1}_U$ have been given, in section 3.13 - just recall that $\varphi \otimes \mathbb{1}_U$ is defined by $x \otimes u \mapsto \varphi(x) \otimes u$. This functor will be denoted by $\bullet \otimes U$, thereby $\varphi \otimes U$ is an abbreviation of $\varphi \otimes \mathbb{1}_U$ (which we try to avoid). Due to the isomorphism $M \otimes U \cong_{\mathrm{m}} U \otimes M$ there is no reason to study the functor $U \otimes \bullet$ separately.

- If $\mathcal{C}$ is any category and $A \in \mathrm{obj}(\mathcal{C})$ is any fixed object of $\mathcal{C}$, then we obtain a covariant functor H_A by assigning each object $Y \in \mathrm{obj}(\mathcal{C})$ the set of morphisms $\mathcal{C}(A, Y)$ and each morphism $\psi \in \mathcal{C}$ the map $H_A(\psi) : \mathcal{C}(A, X) \to \mathcal{C}(A, Y)$ defined by $H_A(\psi)(\varphi) := \psi \circ \varphi$.

$$\begin{aligned} \mathcal{C} &\to \mathbf{Set} \\ Y &\mapsto \mathcal{C}(A, Y) \\ \psi &\mapsto \big(\varphi \mapsto \psi \circ \varphi\big) \end{aligned}$$

 The functor H_A is called **covariant hom-functor** and we usually write $\mathcal{C}(A, \bullet)$, for it e.g. $\mathrm{mhom}(A, \bullet)$ in case of $\mathcal{C} = \mathbf{Mod}_R$. Then the notation $\mathcal{C}(A, X) = H_A(X)$ is straightforward and $\mathcal{C}(A, \psi) = H_A(\psi) : \varphi \mapsto \psi \circ \varphi$ stands to reason. In complete analogy, fixing an object $B \in \mathrm{obj}(\mathcal{C})$ we obtain the **contra-variant hom-functor** $\mathcal{C}(\bullet, B)$ by

$$\begin{aligned} \mathcal{C} &\to \mathbf{Set} \\ X &\mapsto \mathcal{C}(X, B) \\ \varphi &\mapsto \big(\psi \mapsto \psi \circ \varphi\big) \end{aligned}$$

- Our last example is the foundation of algebraic geometry: The **spectrum functor**, that assigns every commutative ring $(R, +, \cdot)$ its *spectrum*, that is its set of prime ideals

$$\mathrm{Spec}(R) \;=\; \{\, \mathfrak{p} \trianglelefteq_{\mathrm{i}} R \mid \forall\, a, b \in R : ab \in \mathfrak{p} \implies a \in \mathfrak{p} \text{ or } b \in \mathfrak{p} \,\}$$

 Recall the notation $\mathbb{V}(\mathfrak{a}) := \{\, \mathfrak{p} \in \mathrm{Spec}(R) \mid \mathfrak{a} \subseteq \mathfrak{p} \,\}$, these are taken to be the *closed* sets of $\mathrm{Spec}(R)$. That is we get a topology on $\mathrm{Spec}(R)$ (called the *Zariski-topology*) by letting

$$\mathcal{Z}_R \;:=\; \{\, \mathrm{Spec}(R) \setminus \mathbb{V}(\mathfrak{a}) \mid \mathfrak{a} \trianglelefteq_{\mathrm{i}} R \,\}$$

It is easy to see, that the closed points in this topology are precisely the maximal ideals of R. And as for a ring homomorphism $\varphi : R \to S$ we have that $\varphi^{-1}(\mathfrak{q}) \trianglelefteq_{\mathrm{i}} R$ is prime, for any prime ideal $\mathfrak{q} \trianglelefteq_{\mathrm{i}} S$. Thus we obtain a well-defined map $\mathrm{Spec}(\varphi) : \mathrm{Spec}(S) \to \mathrm{Spec}(R)$ defined, by $\mathrm{Spec}(\varphi)(\mathfrak{q}) := \varphi^{-1}(\mathfrak{q})$. And this even is continuous for the Zariski-topology, as $\varphi^{-1}(\mathbb{V}(\mathfrak{b})) = \mathbb{V}(\varphi^{-1}(\mathfrak{b}))$ Altogether we have a contra-variant functor, given by

$$\begin{array}{rcl} \textbf{Ring} & \to & \textbf{Top} \\ R & \mapsto & \big(\mathrm{Spec}(R),\, \mathcal{Z}_R\big) \\ \varphi & \mapsto & \big(\mathfrak{q} \mapsto \varphi^{-1}(\mathfrak{q})\big) \end{array}$$

(11.25) Definition:
Let $\mathcal{C}$ and $\mathcal{D}$ be any categories and $F : \mathcal{C} \to \mathcal{D}$ be a covariant functor. By definition, for any two objects $X, Y \in \mathrm{obj}(\mathcal{C})$, F induces a map of the following form

$$\mathcal{C}(X,Y) \to \mathcal{D}\big(F(X),F(Y)\big) \,:\, \varphi \mapsto F(\varphi)$$

In the case of a contra-variant functor, all we have to do is substitute the range of this map by $\mathcal{D}(F(Y),F(X))$. Now F is said to be **faithful**, iff for any $X, Y \in \mathrm{obj}(\mathcal{C})$ the above map $\varphi \mapsto F(\varphi)$ is injective. And F is said to be **full**, iff for any $X, Y \in \mathrm{obj}(\mathcal{C})$ this map $\varphi \mapsto F(\varphi)$ is surjective.
And we say that the functor F is **essentially surjective**, iff for any object $Y \in \mathrm{obj}(\mathcal{C})$ there is an object $X \in \mathrm{obj}(\mathcal{C})$ such that $Y \cong E(X)$ are isomorphic.

(11.26) Proposition: (viz. 1327)
Let $\mathcal{C}$ and $\mathcal{D}$ be any categories and $F : \mathcal{C} \to \mathcal{D}$ be a covariant functor. Consider any two objects X and $Y \in \mathrm{obj}(\mathcal{C})$, then we obtain the following statements

(i) If $\Phi \in \mathcal{C}(X,Y)$ is an isomorphism, then $F(\varphi) \in \mathcal{D}(F(X),F(Y))$ is an isomorphism, too. And its inverse is given to be $F(\Phi)^{-1} = F(\Phi^{-1})$.

(ii) If F is full and faithful and $\Theta \in \mathcal{D}(F(X),F(Y))$ is an isomorphism, then there is a (uniquely determined) isomorphism $\Phi \in \mathcal{C}(X,Y)$ such that $F(\Phi) = \Theta$.

(iii) If F is full and faithful such that $F(X) = F(Y)$, then the objects $X \cong Y$ are isomorphic.

(11.27) Definition:
Let $\mathcal{C}$ and $\mathcal{D}$ be any categories and let $F : \mathcal{C} \to \mathcal{D}$ be any functor (co- or contravariant). Then F is said to be an **isofunctor**, iff there is another functor $\overline{F} : \mathcal{D} \to \mathcal{C}$ such that $F\overline{F}$ is the identity on $\mathcal{D}$ and $\overline{F}F$ is the identity on $\mathcal{C}$. More formally, we require the following properties

(1) $\forall\, U \in \mathrm{obj}(\mathcal{C})$ we get $\overline{F}(F(U)) = U$

(2) $\forall\, X \in \mathrm{obj}(\mathcal{D})$ we get $F(\overline{F}(X)) = X$

(3) $\forall\, U, V\mathrm{obj}(\mathcal{C})$ and $\varphi \in \mathcal{C}(U,V)$ we get $\overline{F}(F(\varphi)) = \varphi$

(4) $\forall\, X, Y\mathrm{obj}(\mathcal{D})$ and $\psi \in \mathcal{D}(X,Y)$ we get $F(\overline{F}(\psi)) = \psi$

We say that $\mathcal{C}$ and $\mathcal{D}$ are **isomorphic**, iff there is an isofunctor $F : \mathcal{C} \to \mathcal{D}$ and we denote this by $F : \mathcal{C} \xrightarrow{\sim} \mathcal{D}$ or simply by $\mathcal{C} \cong \mathcal{D}$. Nota it is clear that $\cong$ thereby has the properties of an equivalence relation. That is (1) $\mathcal{C} \cong \mathcal{C}$, (2) $\mathcal{C} \cong \mathcal{D}$ implies $\mathcal{D} \cong \mathcal{C}$ and (3) $\mathcal{C} \cong \mathcal{D}$ and $\mathcal{D} \cong \mathcal{E}$ implies $\mathcal{C} \cong \mathcal{E}$.

(11.28) Definition:
Let $\mathcal{C}$ and $\mathcal{D}$ be any categories and let $F, G : \mathcal{C} \to \mathcal{D}$ be any two covariant functors. Then a collection $\eta = (\eta_X)$ where $X \in \mathrm{obj}(\mathcal{C})$ is said to be a **natural transformation** from F to G, iff we get

(1) $\forall\, X \in \mathrm{obj}(\mathcal{C})$ we find $\eta_X \in \mathcal{D}(F(X), G(X))$

(2) $\forall\, X, Y \in \mathrm{obj}(\mathcal{C}), \forall\, \varphi \in \mathcal{C}(X, Y)$ we find the commutativity of the diagram $\eta_Y F(\varphi) = G(\varphi)\eta_X$ where the left-downwards morphisms is η_X and the right-downwards morphism is η_Y

$$\begin{array}{ccc} F(X) & \xrightarrow{F(\varphi)} & F(Y) \\ \downarrow & & \downarrow \\ G(X) & \xrightarrow{G(\varphi)} & G(Y) \end{array}$$

In this case we write $\eta : F \rightrightarrows G$. We say that η is a **natural isomorphism** iff (3) for any object $X \in \mathrm{obj}(\mathcal{C})$ the morphism $\eta_X : F(X) \xrightarrow{\sim} D(X)$ even is an isomorphism. And in this case F and G are said to be **naturally isomorphic**, which we denote by $F \cong G$. It is obvious how to define natural transformations between contravariant functors: Property (1) remains unchanged and in the diagram of property (2) we just have to reverse the direction of the horizontal arrows, that is $\eta_X F(\varphi) = G(\varphi)\eta_Y$.

(11.29) Example:
The following example is artificial, but illustrates the workings of a natural transformation: We regard the category **Set** of sets and define the functor $F : \mathbf{Set} \to \mathbf{Set}$ by $F(X) := X \times X$ for any set X and $F(f) : (x_1, x_2) \to (f(x_1), f(x_2))$ for any function $f : X \to Y$. The functor $G : \mathbf{Set} \to \mathbf{Set}$ is just the identity $G(X) := X$ and $G(f) := f$. Then $\eta = (\eta_X)$ is a natural transformation $\eta : F \rightrightarrows G$, where we define $\eta_X : X \times X \to X : (x_1, x_2) \mapsto x_1$.

(11.30) Definition:
Let $\mathcal{C}$ and $\mathcal{D}$ be any categories, then the pair $(E, \overline{E})$ is said to be an **equivalence** of the categories $\mathcal{C}$ and $\mathcal{D}$, iff we get the following properties (1) to (4). And in this case we write $(E, \overline{E}) : \mathcal{C} \sim \mathcal{D}$.

(1) $E : \mathcal{C} \to \mathcal{D}$ is a functor

(2) $\overline{E} : \mathcal{D} \to \mathcal{C}$ is a functor

(3) There is a collection (Φ_X) where $X \in \mathrm{obj}(\mathcal{C})$, such that any $\Phi(X) : X \to \overline{E}(E(X))$ is an isomorphism of $\mathcal{C}$ such that for any two objects X, $X' \in \mathrm{obj}(\mathcal{C})$ and any morphism $\varphi \in \mathcal{C}(X, X')$ we get the commutativity of the diagram $\Phi_{X'} \circ \varphi = \overline{E}(E(\varphi)) \circ \Phi_X$. That is the following diagram, where the left-downwards morphisms is Φ_X and the right-downwards morphism is $\Phi_{X'}$:

$$\begin{array}{ccc} X & \xrightarrow{\varphi} & X' \\ \downarrow & & \downarrow \\ \overline{E}(E(X)) & \xrightarrow{\overline{E}(E(\varphi))} & \overline{E}(E(X')) \end{array}$$

(4) There is a collection (Θ_Y) where $Y \in \mathrm{obj}(\mathcal{D})$, such that any $\Theta_Y : Y \to E(\overline{E}(Y))$ is an isomorphism of $\mathcal{D}$ such that for any two objects Y, $Y' \in \mathrm{obj}(\mathcal{D})$ and any morphism $\psi \in \mathcal{D}(Y, Y')$ we get the commutativity of the diagram $\Theta_{Y'} \circ \psi = E(\overline{E}(\psi)) \circ \Theta_Y$. That is the following diagram, where the left-downwards morphisms is Θ_Y and the right-downwards morphism is $\Theta_{Y'}$:

$$\begin{array}{ccc} Y & \xrightarrow{\psi} & Y' \\ \downarrow & & \downarrow \\ E(\overline{E}(Y)) & \xrightarrow{E(\overline{E}(\psi))} & E(\overline{E}(Y')) \end{array}$$

(11.31) Proposition: (viz. 1327)

(i) Equivalence of categories has the properties of an equivalence relation. That is for any categories $\mathcal{B}$, $\mathcal{C}$ and $\mathcal{D}$ we have the following properties: (1) $(\mathbb{1}, \mathbb{1}) : \mathcal{C} \sim \mathcal{C}$ under the identity functor $\mathbb{1}(X) := X$ and $\mathbb{1}(\varphi) := \varphi$. (2) If $(E, \overline{E}) : \mathcal{C} \sim \mathcal{D}$ is an equivalence of categories, then $(\overline{E}, E) : \mathcal{D} \sim \mathcal{C}$ is an equivalence of categories, as well. And (3) if $(D, \overline{D}) : \mathcal{B} \sim \mathcal{C}$ and $(E, \overline{E}) : \mathcal{C} \sim \mathcal{D}$ are equivalences of categories, then $(ED, \overline{DE}) : \mathcal{B} \sim \mathcal{D}$ is an equivalence of categories, again.

(ii) If $(E, \overline{E}) : \mathcal{C} \sim \mathcal{D}$ is an equivalence of the categories $\mathcal{C}$ and $\mathcal{D}$, then both, E and $\overline{E}$ are have all of the properties: They are full, faithful and essentially surjective.

(iii) If $E : \mathcal{C} \to \mathcal{D}$ is a (covariant) full, faithful and essentially surjective functor from the category $\mathcal{C}$ to the category $\mathcal{D}$, then E admits a *quasi-inverse* $\overline{E} : \mathcal{D} \to \mathcal{C}$, such that $(E, \overline{E}) : \mathcal{C} \sim \mathcal{D}$ is an equivalence of categories. A construction of $\overline{E}$ is given in the proof.

(iv) Let $\mathcal{C}$ and $\mathcal{D}$ be any categories and $E : \mathcal{C} \to \mathcal{D}$ and $\overline{E} : \mathcal{D} \to \mathcal{C}$ be covariant functors. Then the following statements are equivalent

 (a) $(E, \overline{E}) : \mathcal{C} \sim \mathcal{D}$ is an equivalence of categories

 (b) The compositions $E\overline{E}$ and $E\overline{E}$ are naturally isomorphic to the respective identity functors: That is we have $E\overline{E} \cong \mathbb{1}_{\mathcal{D}}$ and $\overline{E}E \cong \mathbb{1}_{\mathcal{C}}$.

categories: $\mathbf{C}_S$, $\mathbf{C}^\bullet$, $\mathbf{Bun}_\bullet$,
representable functors, Yoneda's lemma

11.3 Universal Properties

Categories are a very general concept. It's objects don't even have to be sets, like for example topological spaces, that consist of a base set X and a topology $\mathcal{T}$ on X. The cartesian product, for example, is a widely construction, that spawned direct products and direct sums. As is this construction can only be applied to sets. So how can we transfer this concept to general objects of a category?
The answer lies in studying the structure the cartesian product provides: It comes with projections from the product to the base sets, composing it. So in category theory we no longer use constructions of these objects, but rather fix how this new object interacts with others. If these properties are rigorous enough, the new object, e.g. the product, will be uniquely determined - up to isomorphism. Such a definition of an object by its properties is called a *universal property*.
The drawback is: By prescribing a universal property, it is neither clear, whether such an object exists, nor is it determined uniquely. We can only say, that any two objects satisfying a certain universal property are isomorphic. The existence can only be shown using a suitable construction, in the category given. The advantage is, that we get a unified treatment of like constructions (such as products) across very different categories. Let us start with the concept of products:

(11.32) Definition:
Consider any category $\mathcal{C}$, a non-empty index set I and for any $i \in I$ let $X_i \in \mathrm{obj}(\mathcal{C})$ be an object of $\mathcal{C}$. Then the (P, π_i) is said to be a **product** of the X_i, iff it satisfies the following three properties

(1) $P \in \mathrm{obj}(\mathcal{C})$ is an object of $\mathcal{C}$

(2) For any $i \in I$ we have $\pi_i \in \mathcal{C}(P, X_i)$, a morphism of $\mathcal{C}$

(3) For any other pair (U, φ_i), such that $U \in \mathrm{obj}(\mathcal{C})$ and $\varphi_i \in \mathcal{C}(U, X_i)$ there is a uniquely determined morphism $\varphi \in \mathcal{C}(U, P)$ such that (for any $i \in I$) the following diagrams commutes: $\varphi_i = \pi_i \circ \varphi$.

We continue with the objects X_i above. We likewise say, that (S, ε_i) is a **coproduct** (also called **direct sum**) of the X_i, iff it satisfies the following three, mirrored properties:

(1) $S \in \mathrm{obj}(\mathcal{C})$ is an object of $\mathcal{C}$

(2) For any $i \in I$ we have $E_i \in \mathcal{C}(X_i, S)$, a morphism of $\mathcal{C}$

(3) For any other pair (Y, φ_i), such that $Y \in \mathrm{obj}(\mathcal{C})$ and $\varphi_i \in \mathcal{C}(X_i, Y)$ there is a uniquely determined morphism $\varphi \in \mathcal{C}(S, Y)$ such that (for any $i \in I$) the following diagrams commutes: $\varphi_i = \varphi \circ \varepsilon_i$.

We say that the category $\mathcal{C}$ **admits products**, iff for any index-set I and any family (X_i) of objects, there is a product (P, π_i) of these X_i. Likewise we say that the category $\mathcal{C}$ **admits coproducts**, iff for any index-set I and any family (X_i) of objects, there is a product (S, ε_i) of these X_i.

(11.33) Proposition: (viz. 1330)

(i) Let $\mathcal{C}$ be a category and I a non-empty index set. For any $i \in I$ let $X_i \in \mathrm{obj}(\mathcal{C})$ be an object of $\mathcal{C}$. If both (P, π_i) and (P', π_i') are products of the X_i, then $P \cong P'$ are isomorphic. And thereby this isomorphism $\Phi : P \xrightarrow{\sim} P'$ is the one and only morphism $\Phi \in \mathcal{C}(P, P')$ that satisfies $\pi_i = \pi_i' \circ \Phi$ for any $i \in I$.

(ii) Let $\mathcal{C}$ be a category and I a non-empty index set. For any $i \in I$ let $X_i \in \mathrm{obj}(\mathcal{C})$ be an object of $\mathcal{C}$. If both (S, ε_i) and (S', ε'_i) are coproducts of the X_i, then $S \cong S'$ are isomorphic. And thereby this isomorphism $\Phi : S \xrightarrow{\sim} S'$ is the one and only morphism $\Phi \in \mathcal{C}(S, S')$ that satisfies $\varepsilon'_i = \Phi \circ \varepsilon_i$ for any $i \in I$.

(iii) Products (and coproducts) are preserved under equivalence of categories. Formally this is to say: Let $(E, \overline{E}) : \mathcal{C} \sim \mathcal{D}$ be an equivalence of the categories $\mathcal{C}$ and $\mathcal{D}$. Consider a family of objects $X_i \in \mathrm{obj}(\mathcal{C})$ where $i \in I \neq \emptyset$. Also let $P \in \mathrm{obj}(\mathcal{C})$ and for any $i \in I$ some $\pi_i \in \mathcal{C}(P, X_i)$. Then the following statements are equivalent

(a) (P, π_i) is a (co)product of the X_i

(b) $(E(P), E(\pi_i))$ is a (co)product of the $E(X_i)$

(11.34) Example:

(i) The category **Set** of sets admits products: If I is any non-empty set and for any $i \in I$ we are given an arbitrary set X_i then a product (P, π_i) of the X_i is given by the cartesian product

$$P \;:=\; \prod_{i \in I} X_i \;=\; \{\, (x_i) \mid \forall\, i \in I : x_i \in X_i \,\}$$

under the canonical projections $\pi_j : P \twoheadrightarrow X_j : (x_i) \mapsto x_j$. In fact, if U is any other set and for any $i \in I$ we are given some map $\varphi_i : U \to X_i$, then we can define $\varphi : U \to P$, by $\varphi(u) := (\varphi_i(u))$.

(ii) The category **Set** of sets also admits coproducts: If I is any non-empty set and for any $i \in I$ we are given an arbitrary set X_i then a coproduct (S, ε_i) of the X_i is given by the disjoint union

$$S \;:=\; \bigsqcup_{i \in I} X_i \;=\; \{\, (i, x_i) \mid \forall\, i \in I : x_i \in X_i \,\}$$

under the canonical embeddings $\varepsilon_j : X_j \hookrightarrow S : x_j \mapsto (j, x_j)$. In fact, if Y is any other set and for any $i \in I$ we are given some map $\varphi_i : X_i \to S$, then we can define $\varphi : S \to Y$, by $\varphi(i, x_i) := \varphi_i(x_i)$.

(iii) Fix any ring $(R, +, \cdot)$, then the category $\mathbf{Mod}_R$ of R-modules admits products: Let I be any non-empty set and for any $i \in I$ consider an R-module M_i. The direct product P of the M_i is the cartesian product of the M_i under the component-wise operations, as in (3.29). Then (P, π_i) is a product of the M_i, where $\pi_j : P \twoheadrightarrow M_j : (x_i) \mapsto x_j$ are the canonical projections, again. In fact, if U is any other R-module and for any $i \in I$ we are given an R-linear map $\varphi_i : U \to M_i$ then we can define $\varphi : U \to P$ by $\varphi(u) := \big(\varphi_i(u)\big)$.

(iv) The category $\mathbf{Mod}_R$ of R-modules over the ring R also admits coproducts: Let I be any non-empty set and for any $i \in I$ consider an R-module M_i. Then we take to the direct sum S of the M_i

$$S \;:=\; \bigoplus_{i \in I} M_i$$

and for any $j \in I$ we let $\iota_j : M_j \to S$ by $\iota_j(x_j) := (\overline{x}_i)$ where $\overline{x}_j := x_j$ and $\overline{x}_i := 0_i$ for any $i \in I$ with $i \neq j$. Then (S, ε_i) is a coproduct of the M_i. In fact, if N is any other R-module and for any $i \in I$ we are given an R-linear map $\varphi_i : M_i \to N$, then we can define $\varphi : S \to N$ by $\varphi : (x_i) \mapsto \big(\varphi_i(x_i)\big)$.

(v) The category **Ring** of rings admits products: Let I be any non-empty set and for any $i \in I$ consider a ring $(R_i, +, \cdot)$. The direct product P of the R_i is the cartesian product of the R_i under the componentwise operations, as in (1.94). Then (P, π_i) is a product of the R_i, where $\pi_j : P \twoheadrightarrow R_j : (a_i) \mapsto a_j$ are the canonical projections, again. In fact, if $(U, +, \cdot)$ is any other ring and for any $i \in I$ we are given a ring-homomorphism $\varphi_i : U \to R_i$ then we can define $\varphi : U \to P$ by $\varphi(u) := \big(\varphi_i(u)\big)$.

Coproducts are problematic: There is no obvious way how to define the canonical embeddings $\varepsilon_i : R_i \to S$. If we use the same maps, as in (iv), then the ε_i do not map 1_i to 1_S, even if I is finite. In case of commutative rings we can regard the R_i as $\mathbb{Z}$-algebras. And thereby we find a coproduct in form of the tensor product. This is the next item:

(vi) Fix any ring $(R, +, \cdot)$, then the category $\mathbf{cAlg}_R$ of commutative R-algebras admits *finite* coproducts: That is to say, if A_1 to A_n are commutative R-algebras, then we take to their tensor product, which is a commutative R-algebra, again

$$S \;:=\; A_1 \otimes \ldots \otimes A_n$$

Recall (3.145), there we defined the maps $\varepsilon_j : A_j \to S$, by taking $\varepsilon_1(x_1) := x_1 \otimes 1_2 \otimes \ldots \otimes 1_n$ up to $\varepsilon_n(x_n) := 1_1 \otimes \ldots \otimes 1_{n-1} \otimes x_n$. We have seen there, that these are R-algebra-homomorphisms, that make (S, ε_i) a product in the sense of category theory.

(vii) The category **Top** of topological spaces admits products: If I is any non-empty set and for any $i \in I$ we are given a topological space $(X_i, \mathcal{T}_i)$ then a product $\big((P, \mathcal{T}), \pi_i\big)$ of these is given by the cartesian product P under the product topology, defined in (6.14).

The π_j are the canonical projections $\pi_j : P \twoheadrightarrow X_j : (x_i) \mapsto x_j$ again. It has been shown in (6.29.(xi)), that the map φ in (i) is a morphism again. And therefore this construction truly satisfies the universal property of a product in the sense of category theory.

(11.35) Definition:
Fix any category $\mathcal{C}$ and a partially ordered set $(I, \leq)$. We say that (M_i, μ_i^j) is a **directed system** over I in $\mathcal{C}$, iff the following four properties are satisfied

(1) $\forall\, i \in I$ we get: $M_i \in \mathrm{obj}(\mathcal{C})$ is an object

(2) $\forall\, i, j \in I$ with $i \leq j$ we get: $\mu_i^j \in \mathcal{C}(M_i, M_j)$ is a morphism

(3) $\forall\, i \in I$ we get: $\mu_i^i = \mathbb{1}_{M_i}$ is the identity on M_i

(4) $\forall\, i, j$ and $k \in I$ with $i \leq j$ and $j \leq k$ we get: $\mu_j^k \circ \mu_i^j = \mu_i^k$

In this case the morphisms μ_i^j are said to be the **transition morphisms** of the directed system (M_i, μ_i^j). And (T, τ_i) is said to be a **direct target** of the directed system (M_i, μ_i^j), iff it satisfies the properties

(1) $T \in \mathrm{obj}(\mathcal{C})$ is an object

(2) $\forall\, i \in I$ we get: $\tau_i \in \mathcal{C}(M_i, T)$ is a morphism

(3) $\forall\, i, j \in I$ with $i \leq j$ we get: $\tau_i = \tau_j \circ \mu_i^j$

In this case the morphisms τ_i are said to be the **structural morphisms** of the direct target (T, τ_i). And finally (L, λ_i) is said to be an **direct limit** (or simply a **colimit**) of the directed system (M_i, μ_i^j), iff it is a direct target of (M_i, μ_i^j), that additionally satisfies the following *universal property*:

(4) For any direct target (T, τ_i) of (M_i, μ_i^j) there is a uniquely determined morphism $\tau \in \mathcal{C}(L, T)$ that satisfies the commutativity $\tau_i = \tau \circ \lambda_i$ for any $i \in I$.

(11.36) Definition:
Fix any category $\mathcal{C}$ and a partially ordered set $(I, \leq)$. We say that (M_i, μ_j^i) is an **inverse system** over I in $\mathcal{C}$, iff the following four properties are satisfied

(1) $\forall\, i \in I$ we get: $M_i \in \mathrm{obj}(\mathcal{C})$ is an object

(2) $\forall\, i, j \in I$ with $i \leq j$ we get: $\mu_j^i \in \mathcal{C}(M_j, M_i)$ is a morphism

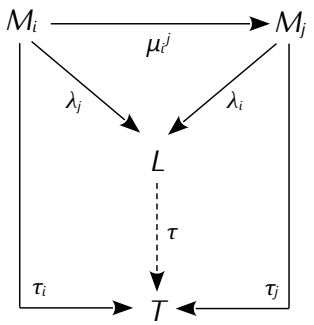
(3) $\forall\, i \in I$ we get: $\mu_i^i = \mathbb{1}_{M_i}$ is the identity on M_i

(4) $\forall\, i, j$ and $k \in I$ with $i \leq j$ and $j \leq k$ we get: $\mu_j^i \circ \mu_k^j = \mu_k^i$

In this case the morphisms μ_j^i are said to be the **transition morphisms** of the inverse system (M_i, μ_j^i). And (T, τ_i) is said to be an **inverse target** of the inverse system (M_i, μ_j^i), iff it satisfies the properties

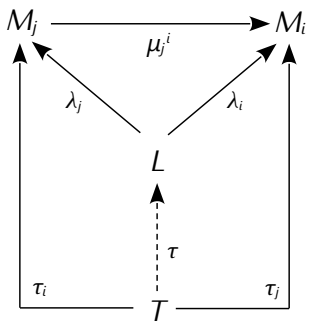
(1) $T \in \mathrm{obj}(\mathcal{C})$ is an object

(2) $\forall\, i \in I$ we get: $\tau_i \in \mathcal{C}(T, M_i)$ is a morphism



(3) $\forall\, i, j \in I$ with $i \leq j$ we get: $\tau_i = \mu_j^i \circ \tau_j$

In this case the morphisms τ_i are said to be the **canonical projections** of the inverse target (T, τ_i). And finally (L, λ_i) is said to be an **inverse limit** (or simply a **limit**) of the inverse system (M_i, μ_j^i), iff it is an inverse target of (M_i, μ_j^i), that additionally satisfies the following *universal property*:



(4) For any inverse target (T, τ_i) of (M_i, μ_j^i) there is a uniquely determined morphism $\tau \in \mathcal{C}(T, L)$ that satisfies the commutativity $\tau_i = \lambda_i \circ \tau$ for any $i \in I$.

(11.37) Remark:
We have studies direct and inverse limits in the category of sets, topological spaces, rings, modules and algebras over a fixed commutative ring R in section 3.14 already. There we have used a constructive approach to find the direct resp. inverse limit. In the general context of category theory we may only rely on on the universal property to define these (up to isomorphism). So let us rewrite the diagrams involved in the definition in terms of the variable symbols used here:

universal property of the direct limit

universal property of the inverse limit

(11.38) Proposition: (viz. 1331)

(i) Let $\mathcal{C}$ be a category and $(I, \leq)$ be a partially ordered set and fix a directed system (M_i, μ_i^j) over I in $\mathcal{C}$. Now, if both (L, λ_i) and (L', λ_i') are direct limits of (M_i, μ_i^j), then $L \cong L'$ are isomorphic. And thereby this isomorphism $\Phi : L \xrightarrow{\sim} L'$ is the one and only morphism $\Phi \in \mathcal{C}(L, L')$ that satisfies $\lambda_i' = \Phi \circ \lambda_i$ for any $i \in I$.

(ii) Let $\mathcal{C}$ be a category and $(I, \leq)$ be a partially ordered set and fix an inverse system (M_i, μ_j^i) over I in $\mathcal{C}$. Now, if both (L, λ_i) and (L', λ_i') are inverse limits of (M_i, μ_j^i), then $L \cong L'$ are isomorphic. And thereby this isomorphism $\Phi : L \xrightarrow{\sim} L'$ is the one and only morphism $\Phi \in \mathcal{C}(L, L')$ that satisfies $\lambda_i = \lambda_i' \circ \Phi$ for any $i \in I$.

(iii) Direct and inverse limits are preserved under equivalence of categories. Formally this is to say: Let $(E, \overline{E}) : \mathcal{C} \sim \mathcal{D}$ be an equivalence of the categories $\mathcal{C}$ and $\mathcal{D}$. Let $(I, \leq)$ be a partially ordered set and (M_i, μ_i^j) be a directed system over I in $\mathcal{C}$. Also let (L, λ_i) be a direct target of (M_i, μ_i^j). Then the following statements are equivalent

 (a) (L, λ_i) is a direct limit of (M_i, μ_i^j)

 (b) $(E(L), E(\lambda_i))$ is a direct limit of $(E(M_i), E(\mu_i^j))$

 Likewise if (M_i, μ_j^i) is an inverse system over I in $\mathcal{C}$ and (L, λ_i) is an inverse target of (M_i, μ_j^i) then the following statements are equivalent

 (a) (L, λ_i) is an inverse limit of (M_i, μ_j^i)

 (b) $(E(L), E(\lambda_i))$ is an inverse limit of $(E(M_i), E(\mu_j^i))$

Chapter 15

All the Proofs

In this chapter we will finally present the proofs of all the statements (propositions, lemmas, theorems and corollaries) that have been given in the previous part. Note that the order of proofs is different from the order in which we gave the statements, though we have tried to stick to the order of the statements as tightly as possible. At some occasions a proof uses methods more advanced, than the current exposition of the topic. In this case the proof has to be postponed until general theory provides the arguments, that have been unavailable. In order to prevent circular conclusions we have to abstain from using these statements, until they can finally be proved. Hence we have taken great care to announce, when a proof cannot be done right away. And of course we do not use this particular statement before that.

15.1 Proofs of Chapter 0

Proof of (0.4):
If $u = x$ and $v = y$ it is clear that $\{u,v\} = \{x,y\}$ and hence $\{\, u,\{u,v\}\,\} = \{\, x,\{x,y\}\,\}$ as well. For the converse direction we need to distinguish two cases: **First case:** If $x = y$, then $\{x,y\} = \{x,x\} = \{x\}$ so in this case our assumption reads as:

$$\{\, u,\{u,v\}\,\} \;=\; \{\, x,\{x\}\,\}$$

That contains 2 assertions: $u \in \{\, x,\{x\}\,\}$ [which implies $u = x$ or $u = \{x\}$ and $\{u,v\} \in \{\, x,\{x\}\,\}$ [which implies $\{u,v\} = x$ or $\{\, u,v\,\} = \{x\}$]. Altogether we find 4 different combinations

	$u = x$	$u = \{x\}$
$\{u,v\} = x$	(1.A)	(1.B)
$\{u,v\} = \{x\}$	(1.C)	(1.D)

It will turn out, that 3 of these cases end in contradiction and the fourth case will yield what we need: In case (1.A) we have $u \in \{u,v\} = x = u$ which would mean $u \in u$ which contradicts the axiom of foundation. In case (1.B) we have $u \in \{u,v\} = x \in \{x\} = u$ such that $u \in x \in u$ which also contradicts the axiom of foundation. In case (1.C) we have $u = x$ and $\{x\} = \{u,v\} = \{x,v\}$. Thus $\{x,v\}$ contains one element only which means $x = v$. As we also have $x = y$ this is $y = x = v$ and hence $y = v$. In case (1.D) we have $u \in \{u,v\} = \{x\}$ such that $u = x$. But as also $x \in \{x\} = u = x$ we have $x \in x$ which contradicts the axiom of foundation, once more. Thus the first case leaves (1.C) only with $u = x$ and $v = y$.

If $u = v$ then we can interchange the roles of u, x and v, y respectively, so this has also been dealt with in the first case. So in the **second case** we may assume $u \neq v$ and $x \neq y$. In this case our assumption

$$\{\, u, \{u, v\}\,\} \;=\; \{\, x, \{x, y\}\,\}$$

contains the first assertion $u = x$ or $u = \{x, y\}$ and the second assertion: $\{u, v\} = x$ or $\{u, v\} = \{x, y\}$. Again we end up with 4 combinations to be considered

	$u = x$	$u = \{x, y\}$
$\{u, v\} = x$	(2.A)	(2.B)
$\{u, v\} = \{x, y\}$	(2.C)	(2.D)

Again it will turn out, that 3 of these cases end in contradictions and the fourth case will yield what we need: In case (2.A) we have $u \in \{u, v\} = x = u$ such that $u \in u$ contradicts the axiom of foundation. In case (2.B) we have $u \in \{u, v\} = x \in \{x, y\} = u$. Therefore $u \in x \in u$ is a contradiction to the axiom of foundation. In (2.C) we get $v \in \{u, v\} = \{x, y\}$. Therefore $v = x$ or $v = y$. But $v = x = u$ if untrue, as we are in case 2. Thus we have $v = y$ and $u = x$ as needed. In case (2.D) we have $u \in \{u, v\} = \{x, y\} = u$ such that $u \in u$ is our last contradiction to the axiom of foundation. Thus the second case leaves (2.C) only with $u = x$ and $v = y$, as well. □

Proof of (0.2):

- By definition for element of $x \in \bigcup_i (A_i \cap B)$ there is some $i \in I$ such that $x \in A_i \cap B$. In particular we get $x \in B$ and $x \in A_i$ for this $i \in I$. The latter is $x \in \bigcup_i A_i$ and as also $x \in B$ this means that x is contained in the set on the left-hand side. Conversely start with

 $$x \;\in\; \left(\bigcup_{i \in I} A_i \right) \cap B$$

 That is $x \in B$ and there is some $i \in I$ such that $x \in A_i$. For this i we get $x \in A_i \cap B$ and hence x is contained in the set on the right-hand side.

- By definition an element of $x \in \bigcap_i (A_i \cup B)$ satisfies $x \in A_i \cup B$ for any $i \in I$. Let us distinguish two cases: If $x \in B$ then x is already contained in the set on the left-hand side. And if $x \notin B$, then $x \in A_i \cup B$ implies $x \in A_i$. As this is true for any $i \in I$ we conclude $x \in \bigcap_i A_i$ such that x is contained in the set on the left-hand side again. Conversely start with

 $$x \;\in\; \left(\bigcap_{i \in I} A_i \right) \cup B$$

 If $x \in B$ then for any $i \in I$ we get $x \in A_i \cup B$ and hence x is contained in the set on the right-hand side. If $x \notin B$ then we necessarily have $x \in \bigcap_i A_i$ which means $x \in A_i$ for any $i \in I$. From this we trivially get $x \in A_i \cup B$, such that x is contained in the set on the right-hand side, in this case, as well.

- This identity is simpler than it looks, we just have to decode what it means for an x to be an element of the respective sets. So let's just do that

$$\begin{aligned} x \in \bigcup_{(i,j)\in I\times J} (A_i \cap B_j) &\iff \exists\,(i,j) \in I \times J \,:\, x \in A_i \cap B_j \\ &\iff \exists\, i \in I\ \exists\, j \in J \,:\, x \in A_i \text{ and } x \in B_j \\ &\iff \big(\exists\, i \in I \,:\, x \in A_i\big) \text{ and } \big(\exists\, j \in J \,:\, x \in B_j\big) \\ &\iff x \in \left(\bigcup_{i\in I} A_i\right) \cap \left(\bigcup_{j\in J} B_j\right) \end{aligned}$$

- For an x to be contained in $\bigcap_{(i,j)} (A_i \cup B_j)$ means $x \in A_i$ or $x \in B_j$ for any $(i,j) \in I \times J$. Likewise we can decode

$$x \;\in\; \left(\bigcap_{i\in I} A_i\right) \cup \left(\bigcap_{j\in J} B_j\right)$$

 to be the property $\forall\, i \in I : x \in A_i$ or $\forall\, j \in J : x \in B_j$. Thus if we start with such an x we may distinguish two cases: If $\forall\, i \in I : x \in A_i$ then $x \in A_i \cup B_j$ is satisfied trivially, for any $(i,j) \in I \times J$. Thus in this case x is contained in the right-hand set. And the same argument works out in the second case $\forall\, j \in J : x \in B_j$. Thus we have found the inclusion "$\subseteq$" and it remains to prove "$\supseteq$": Suppose x was *not* contained in the left-hand side set. Then there had to be some $i \in I$ and $j \in J$ such that $x \notin A_i$ and $x \notin B_j$. So for this combination $(i,j) \in I \times J$ we had $x \notin A_i \cup B_j$. But this contradicts the assumption that x is contained in $\bigcap_{(i,j)} (A_i \cup B_j)$.

- As $A_i \subseteq X$ we know that $x \notin A_i$ is equivalent to $x \in X \setminus A_i$. Using this both identities of the complements are straightforward to see, by elementary quantifier logic

$$\begin{aligned} x \in X \setminus \bigcup_{i\in I} A_i &\iff x \notin \bigcup_{i\in I} A_i \\ &\iff \textit{not}\ \ \forall\, i \in I \,:\, x \in A_i \\ &\iff \exists\, i \in I \,:\, x \notin A_i \\ &\iff x \in \bigcup_{i\in I} X \setminus A_i \\ x \in X \setminus \bigcap_{i\in I} A_i &\iff x \notin \bigcap_{i\in I} A_i \\ &\iff \textit{not}\ \ \exists\, i \in I \,:\, x \in A_i \\ &\iff \forall\, i \in I \,:\, x \notin A_i \\ &\iff x \in \bigcap_{i\in I} X \setminus A_i \end{aligned}$$

□

Proof of (0.7):

- By definition $f(A) = \{\, f(a) \mid a \in A \,\}$ that is $y \in f(A)$ is equivalent to $y = f(a)$ for some $a \in A$. Therefore we can rewrite the following set

$$\begin{aligned} f^{-1}\big(f(A)\big) &= \{\, x \in X \mid f(x) \in f(A) \,\} \\ &= \{\, x \in X \mid \exists\, a \in A : f(x) = f(a) \,\} \end{aligned}$$

And thereby A is contained in this set as for $x = a \in A$ we have $f(x) = f(a)$. If f is injective however, then $f(x) = f(a)$ for some $a \in A$ implies $x = a \in A$ such that this set is contained in A, as well. This is the first property, for the next two we just take a close look

$$\begin{aligned} f\big(f^{-1}(B)\big) &= \Big\{\, f(x) \mid x \in f^{-1}(B) \,\Big\} \\ &= \{\, f(x) \mid x \in X, f(x) \in B \,\} \\ &= \{\, b \in B \mid \exists\, x \in X : b = f(x) \,\} \\ &= B \cap \{\, y \in Y \mid \exists\, x \in X : y = f(x) \,\} \\ &= B \cap \{\, f(x) \mid x \in X \,\} \\ &= B \cap f(X) \\ f^{-1}\big(Y \setminus B\big) &= \{\, x \in X \mid f(x) \in Y \setminus B \,\} \\ &= \{\, x \in X \mid f(x) \notin B \,\} \\ &= X \setminus \{\, x \in X \mid f(x) \in B \,\} \\ &= X \setminus f^{-1}(B) \end{aligned}$$

- Next let us prove the equivalence of $f(A) \subseteq B$ and $A \subseteq f^{-1}(B)$: If we start with $f(A) \subseteq B$, then we have to consider any $a \in A$. Thus we have $f(a) \in f(A) \subseteq B$ by assumption, such that $f(a) \in B$. But $f^{-1}(B) = \{\, x \in X \mid f(x) \in B \,\}$ by definition, so $f(a) \in B$ means $a \in f^{-1}(B)$ and as this is true for any $a \in A$ we have $A \subseteq f^{-1}(B)$. Conversely, if we start with $A \subseteq f^{-1}(B)$ we have to consider any $y \in f(A) = \{\, f(a) \mid a \in A \,\}$. That is $y = f(a)$ for some $a \in A$ but by assumption $A \subseteq f^{-1}(B)$ this means $a \in f^{-1}(B)$ and thereby $f(a) \in B$. Thus $y \in f(A)$ implies $y = f(a) \in B$ and as this is true for any y, we have $f(A) \subseteq B$, as required.
- The properties for the preimage are always easy to verify: Recall the notation of the grand union $\bigcup \mathcal{B}$ to be the union $\bigcup_j B_j$ and compute

$$\begin{aligned} f^{-1}\left(\bigcup \mathcal{B}\right) &= \Big\{\, x \in X \mid f(x) \in \bigcup \mathcal{B} \,\Big\} \\ &= \{\, x \in X \mid \exists\, j \in J : f(x) \in B_j \,\} \\ &= \bigcup_{j \in J} \{\, x \in X \mid f(x) \in B_j \,\} \\ &= \bigcup_{j \in J} f^{-1}(B_j) \\ f^{-1}\left(\bigcap_{j \in J} B_j\right) &= \Big\{\, x \in X \mid f(x) \in \bigcap \mathcal{B} \,\Big\} \\ &= \{\, x \in X \mid \forall\, j \in J : f(x) \in B_j \,\} \\ &= \bigcap_{j \in J} \{\, x \in X \mid f(x) \in B_j \,\} \end{aligned}$$

$$= \bigcap_{j\in J} f^{-1}(B_j)$$

In the second part we already used the grand intersection $\bigcap \mathcal{B}$ which in complete analogy is $\bigcap_j B_j$. The respective properties for the image are a little harder to prove: Note that

$$\bigcup_{i\in I} f(A_i) \;=\; \bigcup_{i\in I} \{\, f(a_i) \mid a_i \in A_i \,\}$$

That is y is an element of this set if and only if there is some $i \in I$ and some $a_i \in A_i$ such that $y = f(a_i)$. On the other hand

$$f\left(\bigcup_{i\in I} A_i\right) \;=\; \{\, f(a) \mid \exists\, i \in I : a \in A_i \,\}$$

That is y is an element of this set if and only if there is some $i \in I$ and some $a \in A_i$ such that $y = f(a)$. Does sound familiar? Yep, it is just the same and hence the sets are equal. In the same manner we proceed with

$$\bigcap_{i\in I} f(A_i) \;=\; \{\, y \in Y \mid \forall\, i \in I\ \exists\, a_i \in A_i : y = f(a_i) \,\}$$

as $y \in f(A_i)$ if and only if there is some $a_i \in A_i$ with $y = f(a_i)$. The other set looks similar, but is not quite the same

$$f\left(\bigcap_{i\in I} A_i\right) \;=\; \{\, y \in Y \mid \exists\, a \in X : \forall\, i \in I : a \in A_i,\, y = f(a) \,\}$$

So if y is in this set, then there is some a with $a \in A_i$ for any $i \in I$ that also satisfies $y = f(a)$. In particular we can take $a_i := a$ and thereby see, that y is hence also contained in $\bigcap_i f(A_i)$, the converse inclusion need not be true however, as the a_i need not be the same a. However if f is injective, then we may fix some $j \in I$. Then for any other $i \in I$ we have $f(a_i) = y = f(a_j)$ such that $a_j = a_i \in A_i$. As this is true for any i we have $a := a_j \in \bigcap_i A_i$ which is the converse inclusion.

□

Proof of (0.10):
Injectivity: If (a) then for any $u, x \in X$ with $f(u) = f(x)$ we have $g(f(u)) = g(f(x))$. But by assumption $gf = \mathbb{1}_X$ we get $u = gf(u) = gf(x) = x$ which is (b) already. Next the implication (b) $\implies$ (c) has already been dealt with in (0.7). So for (c) $\implies$ (d) we start with some $y \in Y$. If there no $x \in X$ with $f(x) = y$ then $f^{-1}(\{\, y \,\}) = \emptyset$ so we have nothing to prove. If there is some $x \in X$ with $f(x) = y$ then we let $A := \{\, x \,\} \subseteq X$. Therefore $f(A) = \{\, f(x) \,\} = \{\, y \,\}$ and by assumption (c) we have $\{\, x \,\} = A = f^{-1}(f(A)) = f^{-1}(\{\, y \,\})$. That is $f^{-1}(\{\, y \,\})$ contains 0 or 1 element which is (d). To return from (d) to (a) we need to find some $g : Y \to X$ with $gf = \mathbb{1}_X$. To do this fix any $x_0 \in X$, then for any $y \in Y$ we define

$$g(y) \;:=\; \begin{cases} x_0 \text{ if } \#f^{-1}(\{\, y \,\}) = 0 \\ x \text{ if } \#f^{-1}(\{\, y \,\}) = 1 \end{cases} \quad \text{where} \quad \{\, x \,\} \;=\; f^{-1}(\{\, y \,\})$$

As we have (c) no other values of $\#f^{-1}(\{\,y\,\})$ may occur and hence g is a well-defined function. If now $y = f(x)$ then $x \in f^{-1}(\{\,y\,\})$ such that we get $g(y) = x$ Concatenating we get $x = g(y) = g(f(x)) = gf(x)$. And as this is true for any $x \in X$ we have found $gf = \mathbb{1}_X$ of (a).

Surjectivity: If (a) then for any $y \in Y$ we consider $x := g(y)$, then from $f(x) = fg(y) = y$ we see that $y \in f(X)$. As y has been arbitrary this is $Y \subseteq f(X) \subseteq Y$ and hence (b). In (0.7) we have seen that for any $B \subseteq Y$ and any $f : X \to Y$ we have $f(f^{-1}(B)) = B \cap f(X)$. Thus if (b) then we get $f(f^{-1}(B)) = B \cap f(X) = B \cap Y = B$ which is (c). Next for the implication (c) $\implies$ (d) we consider any $y \in Y$ and let $B := \{\,y\,\}$. Suppose there was some $y \in Y$ such that $\#f^{-1}(\{\,y\,\}) = 0$. This would mean $f^{-1}(B) = f^{-1}(\{\,y\,\}) = \emptyset$ and thereby $B = f(f^{-1}(B)) = f(\emptyset) = \emptyset$ which is a contradiction. Hence (c) implies (d). To return from (d) to (a) we need to find some $g : Y \to X$ with $fg = \mathbb{1}_Y$. To do this define

$$G \;:\; Y \;\to\; \mathcal{P}(X) \;:\; y \;\mapsto\; f^{-1}(\{\,y\,\})$$

By assumption $G(y) \subseteq X$ is non-empty for any $y \in Y$. Thus by the axiom of choice there is a function $g : Y \to X$ such that for any $y \in Y$ we have $g(y) \in G(y) = f^{-1}(\{\,y\,\})$. That is $f(g(y)) \in \{\,y\,\}$ and thereby $fg(y) = y$. As this is true for any $y \in Y$ we have $fg = \mathbb{1}_Y$ of (a).

Bijectivity: If (a) then we can define $f^{-1} : Y \to X$ by letting $f^{-1}(y) := x$ where $x \in X$ is the one and only x that satisfies $f(x) = y$. Then it is clear, that $f^{-1}(f(x)) = x$ as $f(x)$ satisfies $f(x) = f(x)$. That is $f^{-1}f = \mathbb{1}_X$. Also $f(f^{-1}(y)) = f(x)$ where $x \in X$ satisfies $f(x) = y$. That is $f(f^{-1}(y)) = y$ and therefore $ff^{-1} = \mathbb{1}_Y$. We sill have to prove the uniqueness of f^{-1} that is we consider any two functions $g, h : Y \to X$ such that $gf = \mathbb{1}_x = hf$ and $fg = \mathbb{1}_Y = fh$. Then for any $y \in Y$ we get

$$g(y) \;=\; g(fh(y)) \;=\; g(f(h(y)) \;=\; gf(h(y)) \;=\; h(y)$$

And as $g(y) = h(y)$ for any $y \in Y$ this is $g = h$. Now the implication (b) $\implies$ (c) is trivial, just let $\ell := f^{-1}$ and $r := f^{-1}$ then we are done. Also (c) $\implies$ (d) is clear, as both are the property (a) of an injective, resp. surjective function. To return from (d) to (a) we start with some $y \in Y$. As f is surjective property (b) tells us $Y = f(X) = \{\,f(x) \mid x \in X\,\}$. As $y \in Y$ this means there is some $x \in X$ with $y = f(x)$. For the uniqueness we use property (b) of injective functions: Suppose we had some x_1 and $x_2 \in X$ with $f(x_1) = y$ and $f(x_2) = y$. Then in particular $f(x_1) = f(x_2)$ such that $x_1 = x_2$. That is we found (d) from (a). □

Proof of (0.13):
We first need to verify that $X/\sim$ truly is a partition of X: First of all if $[x] \in X/\sim$ then $[x] \neq \emptyset$ as $x \sim x$ implies $x \in [x]$. Next we need to verify $[x] = [y]$ for any $[x], [y] \in X/\sim$ with $[x] \cap [y] \neq \emptyset$. To do this it suffices to check $[x] \subseteq [y]$, as by the same reasoning we get $[y] \subseteq [x]$. As $[x] \cap [y] \neq \emptyset$ there is some $u \in X$ with $u \in [x] \cap [y]$. By definition of $[x]$ this means $u \sim x$ and likewise $u \sim y$. But by the symmetry of $\sim$ this also is $x \sim u$. If now $z \in [x]$ is any element, then $z \sim x$, too. And thereby we get the chain $z \sim x$ and $x \sim u$ (which implies $z \sim u$) and $u \sim y$ such that $z \sim y$. This again is $z \in [y]$ and as z has been arbitrary this is $[x] \subseteq [y]$. Altogether we have proved property (2) of partitions. But property (3) is easy again: as $x \in [x]$ for any $x \in X$ we see that X is contained in the grand union of $X/\sim$.

Let us also prove that for any partition $\mathcal{A}$ of X the relation $\sim_{\mathcal{A}}$ truly is an equivalence relation: First of all, if $x \in X$ then there is some $A \in \mathcal{A}$ such that $x \in A$ by property (3) of partitions. Thereby $\{x,x\} = \{x\} \subseteq A$ such that $x \sim_{\mathcal{A}} x$. The symmetry of $\sim_{\mathcal{A}}$ is easy: Suppose $x \sim_{\mathcal{A}} y$ that is $\{x,y\} \subseteq A$ for some $A \in \mathcal{A}$. As $\{y,x\} = \{x,y\}$ we also have $\{y,x\} \subseteq A$ such that $y \sim_{\mathcal{A}} x$, as well. Finally we have to verify the transitivity: That is we consider $x \sim_{\mathcal{A}} y$ and $y \sim_{\mathcal{A}} z$. By construction there are some $A, B \in \mathcal{A}$ such that $\{x,y\} \subseteq A$ and $\{y,z\} \subseteq B$. In particular $y \in A \cap B$ such that $A \cap B \neq \emptyset$ implies $A = B$. But then we have $\{x,z\} \subseteq \{x,y,z\} \subseteq A = B$ such that $x \sim_{\mathcal{A}} z$, as well.

So far we have seen that both $\sim \mapsto X/\sim$ and $\mathcal{A} \mapsto \sim_{\mathcal{A}}$ are well defined maps. To prove that $\sim \mapsto X/\sim$ is bijective it suffices to show that $\mathcal{A} \mapsto \sim_{\mathcal{A}}$ is the inverse map. For the one direction we need to show: If we start with $\sim$ and let $\mathcal{A} := X/\sim$ then we have $\sim = \sim_{\mathcal{A}}$. That is we have to prove the following equivalence for any $x, y \in X$

$$x \sim y \iff x \sim_{\mathcal{A}} y$$

For the implication from left to right we have $x \sim y$ which is $x \in [y]$. As $y \in [y]$ is generally true we find $\{x,y\} \subseteq [y]$ such that $x \sim_{\mathcal{A}} y$. If conversely $x \sim_{\mathcal{A}} y$ then $\{x,y\} \subseteq [z]$ for some $z \in X$. In particular $x \sim z$ and $y \sim z$. But as $\sim$ is an equivalence relation this also is $z \sim y$ and hence $x \sim y$. Thus we have the equivalence of the statements. And thus we found $\sim \mapsto \mathcal{A} := X/\sim \mapsto \sim_{\mathcal{A}} = \sim$ For the other direction we need to show: If we start with $\mathcal{A}$ then

$$\mathcal{A} = {}^{X}\big/_{\sim_{\mathcal{A}}}$$

As the equivalence relation now is $\sim_{\mathcal{A}}$ let us write $[x]_{\mathcal{A}}$ for the equivalence class of $x \in X$, that is $[x]_{\mathcal{A}} = \{u \in X \mid u \sim_{\mathcal{A}} x\}$. If $A \in \mathcal{A}$ then there is some $x \in A$, as $A \neq \emptyset$. We will now prove that

$$x \in A \implies A = [x]_{\mathcal{A}}$$

For the inclusion $A \subseteq [x]_{\mathcal{A}}$ we consider any $a \in A$, as $x \in A$ as well this means $\{a,x\} \subseteq A$ such that $a \sim_{\mathcal{A}} x$ which again is $a \in [x]_{\mathcal{A}}$. Conversely if $u \in [x]_{\mathcal{A}}$ then we have $u \sim_{\mathcal{A}} x$ which in turn is $\{u,x\} \subseteq B$ for some $B \in \mathcal{A}$. But as $x \in A$ and $x \in B$ we have $x \in A \cap B$ and therefore $B = A$ by property (2) of the partition $\mathcal{A}$. In particular we see $u \in B = A$ such that $[x]_{\mathcal{A}} \subseteq A$, as well.
So if $A \in \mathcal{A}$ then $A = [x]_{\mathcal{A}}$ for some $x \in X$ and thereby $A \in X/\sim_{\mathcal{A}}$. If conversely $[x]_{\mathcal{A}}$ is any equivalence class of $\sim_{\mathcal{A}}$ then $x \sim_{\mathcal{A}} x$ implies $x \in \{x,x\} \subseteq A$ for some $A \in \mathcal{A}$. Now $x \in A$ implies $A = [x]_{\mathcal{A}}$ again, such that $[x]_{\mathcal{A}} = A \in \mathcal{A}$. That is these two partitions are equal and altogether we have verified that $\mathcal{A} \mapsto \sim_{\mathcal{A}} \mapsto X/\sim_{\mathcal{A}} = \mathcal{A}$. That is the maps $\sim \mapsto X/\sim$ and $\mathcal{A} \mapsto \sim_{\mathcal{A}}$ are mutually inverse. In particular they are bijective which we had to prove. □

Proof of (0.19):
Let $F = \{x_1, \ldots, x_n\}$, then we will prove the claims by induction on n: For $n = 1$ we have $F^* = \{x_1\}$ and $\max(F) = x_1$ as there is no other element of F to compare it with. For the induction step let $F_0 := \{x_1, \ldots, x_{n-1}\}$ such that $F = F_0 \cup \{x_n\}$.

First consider a total order $\leq$: If $x_i \leq x_n$ for any $1 \leq i < n$ then $\max(F) = x_n$. Otherwise (as $\leq$ is total) there is some x_i with $x_n \leq x_i$. And by induction hypothesis F_0 has a greatest element g. Therefore $x_n \leq x_i \leq g$ implies $x_n \leq g$. Thus $\max(F) = g$. In both cases F has a greatest element, as claimed.

Now consider a partial order $\leq$: By induction hypothesis F_0 has a maximal element m. If now $m \leq x_n$ then x_n is a maximal element: Suppose $x_n \leq f$ for some $f \in F_0$. Then $m \leq x_n \leq f$ implies $m \leq f$ and hence $m = f$, as m was maximal in F_0. Then $f = m \leq x_n \leq f$ implies $x_n = f$. Conversely if $\neg(x \leq x_n)$ then m is a maximal element: If $f \in F$ is any set then either $f \in F_0$ for which we have $m \leq f \implies f = m$ due to the maximality of m in F_0 or $f = x_n$. But in the latter case $m \leq f$ is untrue, so there is nothing to prove. In both cases F has a maximal element, which had to be shown.

The respective statements for the least element and minimal elements of F follow immediately if we consider the opposite order $x \leq' y \iff y \leq x$. □

Proof of (0.20):
First of all it suffices to to prove this for minima, as the same property for maxima follows by going to the inverse relation $x \geq y \iff y \leq x$. Let us first distinguish the case $n = 2$: As $\min\{ x_1 \} = x_1$ we get $\min\{ \min\{ x_1 \}, x_2 \} = \min\{ x_1, x_2 \}$ and likewise $\min\{ x_1, \min\{ x_2 \} \} = \min\{ x_1, x_2 \}$.
Now for $n \geq 3$ we will distinguish two cases: First of all assume $\min\{ x_1, \ldots, x_n \} = x_n$ and let $x_m = \min\{ x_1, \ldots, x_{n-1} \}$. Then by assumption $x_n \leq x_i$ for any $i \in 1 \ldots (n-1)$ and in particular $x_n \leq x_m$ such that

$$\min\{ \min\{ x_1, \ldots, x_{n-1} \}, x_n \} = \min\{ x_m, x_n \} = x_n = \min\{ x_1, \ldots, x_n \}$$

Also, as $x_n \leq x_i$ for any $i \in 2 \ldots n$ we have $\min\{ x_2, \ldots, x_n \} = x_n$ and as also $x_n \leq x_1$ we have $\min\{ x_1, x_n \} = x_n$ as well. From this we also get the equality

$$\min\{ x_1, \min\{ x_2, \ldots, x_n \} \} = \min\{ x_1, x_n \} = x_n = \min\{ x_1, \ldots, x_n \}$$

Conversely let $x_m = \min\{ x_1, \ldots, x_n \}$ be the minimal element and assume $x_m < x_{n+1}$. Then in particular $x_m = \min\{ x_1, \ldots, x_{n-1} \}$ and $\min\{ x_m, x_n \} = x_m$ such that we find

$$\min\{ \min\{ x_1, \ldots, x_{n-1} \}, x_n \} = \min\{ x_m, x_n \} = x_m = \min\{ x_1, \ldots, x_n \}$$

For the second equality we first note $x_m = \min\{ x_2, \ldots, x_m \}$ again and as also $x_m \leq x_1$ such that $\min\{ x_1, x_m \} = x_m$ from which we conclude once more

$$\min\{ x_1, \min\{ x_2, \ldots, x_n \} \} = \min\{ x_1, x_m \} = x_m = \min\{ x_1, \ldots, x_n \}$$

□

Proof of (0.21):
Consider any to $x, y \in \bigcap_i C_i$ - as I is non-empty there is some $i \in I$ and hence $x, y \in C_i$. But as $C_i \subseteq X$ is a chain this implies $x \leq y$ or $y \leq x$. And as this is true for any $x, y \in \bigcap_i C_i$ we find, that $\bigcap_i C_i \subseteq X$ is a chain in X again.
Consider any to $x, y \in \bigcup_i C_i$ - that is $x \in C_i$ and $y \in C_j$ for some $i, j \in I$. As the C_i form a net under inclusion there is some $k \in I$ such that $C_i \subseteq C_k$ and $C_j \subseteq C_k$. In particular $x \in C_i \subseteq C_k$ implies $x \in C_k$ and likewise $y \in C_k$. But as $C_k \subseteq X$ is a chain this implies $x \leq y$ or $y \leq x$. And as this is true for any $x, y \in \bigcup_i C_i$ we find, that $\bigcup_i C_i \subseteq X$ is a chain in X again. □

Proof of (0.22):
Let us first verify the equivalence of (a) and (b): For (a) $\implies$ (b) consider any $x \in X$ and let $y := f(x)$. Then $y \leq f(x)$ is a given such that (a) implies $x \leq g(y) = gf(x)$. Likewise for any $y \in Y$ we let $x := g(y)$ such that (a) also yields $y \leq f(x) = fg(y)$ from $x \leq g(y)$.Conversely for (b) $\implies$ (a) we start with $x \leq g(y)$. As f is anti-tonous, this implies $f(x) \geq fg(y) \geq y$ by (b) and hence $y \leq f(x)$. Likewise $y \leq f(x)$ implies $g(y) \geq gf(x) \geq x$ such that $x \leq g(y)$.

Next we prove that (a) and (b) $\implies$ (c): For any $x \in X$ let $Y_x := \{\, y \in Y \mid x \leq g(y) \,\}$, then we have to verify $f(x) = \max(Y_x)$. First of all we have $x \leq gf(x) = g(f(x))$ by (b), which means $f(x) \in Y_x$. And if we pick up any $y \in Y_x$ then $x \leq g(y)$ implies $y \leq f(x)$ due to (a). Thus $f(x)$ is a greatest element of Y_x.

Reversing the roles of f and g we likewise find that $g(y)$ is a maximal element of $X_y := \{\, x \in X \mid y \leq f(x) \,\}$. The same reasoning shows (c) $\implies$ (a): Since $f(x)$ is a greatest element of Y_x we find that $x \leq g(y)$ is $y \in Y_x$ and hence $y \leq f(x)$. Again reversing the roles turns $y \leq f(x)$ into $x \in X_y$ and hence $x \leq g(y)$. Thus we have established the equivalence of (a) and (c), as well.

Let us now prove, that (b) implies $fgf = f$ and $gfg = g$: We start with $x \leq gf(x)$, as f is anti-tonic we get $f(x) \geq f(gf(x)) = fg(f(x)) \geq f(x)$, where we used (b) again. Together $f(x) \geq fgf(x) \geq f(x)$ implies $fgf(x) = f(x)$. Likewise $y \leq fg(y)$ turns into $g(y) \geq g(fg(y)) = fg(g(y)) \geq g(y)$ such that $g(y) \geq fgf(y) \geq g(y)$ also is $fgf(y) = g(y)$.

And from this property we get the one-to-one correspondence of the images: We note that by $g(Y) \subseteq X$ we have $f(g(Y)) \subseteq f(X)$ and therefore the map $f : g(Y) \to f(X)$ is well-defined. Likewise $g : f(X) \to g(Y)$ is well-defined. Now consider any $x = f(y) \in g(Y)$, then $gf(x) = gfg(y) = g(y) = x$, that is gf is the identity map on $g(Y)$. In complete analogy we find for any $y = f(x) \in f(X)$ that $fg(y) = fgf(x) = f(x) = y$ such that fg is the identity map on $f(X)$. That means that f and g are mutually inverse $f = g^{-1}$ and hence form a one-to-one correspondence. □

Proof of (0.25):
Let us prove the equivalences for the ACC first: The implication (a) $\implies$ (b) is quite easy to see: Given an ascending chain $(x_k) \subseteq X$ (where $k \in \mathbb{N}$), that is $x_0 \leq x_1 \leq x_2 \leq \ldots$, let us take $A := \{\, x_k \mid k \in \mathbb{N} \,\}$. By assumption A has a maximal element $a^* \in A$. Pick up some $s \in \mathbb{N}$ such that $a^* = x_s$. If now $i \in \mathbb{N}$, then (as (x_k) is an ascending chain) we have $x_s \leq x_{s+i}$. But due to the maximality of $x_s = a^*$ this already is $x_{s+i} = x_s$.

The implication (b) $\implies$ (a) will be proved as $\neg$ (a) $\implies$ $\neg$ (b), which is only slightly more difficult: As (a) is untrue there is some non-empty subset $A \subseteq X$ without maximal element. Negating the statement that A contains a maximal element yields:

$$\forall\, a \in A\ \exists\, b \in A\ :\ a < b$$

That is (by the axiom of choice) we may pick up a map $\nu : A \to A$ such that $\nu(a) := b$ for some $b \in A$ with $a < b$. And as A is non-empty we may start with some $x_0 \in A$. Now recursively define $x_{k+1} := \nu(x_k) = \nu^k(x_0)$. Then by construction we have found an infinitely ascending chain of elements $x_0 < x_1 < x_2 < \ldots$ which is the negation of (a).

For the equivalences of of the DCC we take $(X, \geq)$ as a partially ordered set under the inverse order $x \geq y \ :\Longleftrightarrow \ y \leq x$. A minimal element of $\leq$ is a maximal element of $\geq$. And the DCC for $\leq$ is the ACC for $\geq$. We already have already established the equivalence of (a) and (b) for the ACC of $(X, \geq)$, so this is the equivalence of (a) and (b) for the DCC of $(X, \leq)$. □

Proof of (0.26):
Let us first prove (a) $\implies$ (c): So consider any chain $C \subseteq X$, if $C = \emptyset$, then it is finite, so we may assume $C \neq \emptyset$. We will construct an ascending sequence of elements, to do so start with $C_0 := C$. As $C_0 \neq \emptyset$ and $(X, \leq)$ satisfies DCC we may choose a minimal element in C_0

$$x_0 \ \in \ \big(C_0\big)_*$$

Suppose we already have $x_0, x_1, \ldots, x_n \in C$ such that $x_0 < x_1 < \cdots < x_n$ then we continue with $C_{n+1} := C \setminus \{ x_0, x_1, \ldots, x_n \}$. If still $C_{n+1} \neq \emptyset$ then we may choose a minimal element again

$$x_{n+1} \ \in \ \big(C_{n+1}\big)_*$$

Suppose we had $x_{n+1} \leq x_n$ then, as $x_{n+1} \in C_{n+1} \subseteq C_n$ and x_n is minimal in C_n this would imply $x_{n+1} = x_n$. But then $x_n \in C_{n+1}$ which is untrue by construction of C_{n+1}. But as $x_{n+1} \leq x_n$ is false, then $x_n < x_{n+1}$ as any two elements of C are comparable. Thus we are able to construct a strictly increasing chain of elements

$$x_0 \ < \ x_1 \ < \ \ldots \ < \ x_n \ < \ x_{n+1}$$

of arbitrary length. But as $(X, \leq)$ also satisfies ACC there is no infinite strictly increasing sequence in X. That means, that at some stage $s \in \mathbb{N}$ we cannot continue to append elements and this only is the case if $C_{s+1} = \emptyset$. But this means that $C = \{ x_0, x_1, \ldots, x_s \}$ is a finite set.

Next we will prove (c) $\implies$ (b): Starting with an ascending sequence of finite chains $C_0 \subseteq C_1 \subseteq C_2 \subseteq \ldots$ in X we need to show that this chain stabilizes eventually. Let us define

$$C \ := \ \bigcup_{k=0}^{\infty} C_k \ \subseteq \ X$$

As $(C_k) \subseteq \mathcal{C}_0(X, \leq)$ is totally ordered under $\subseteq$ and any $C_k \subseteq X$ is a chain (0.21) tells us, that $C \in \mathcal{C}(X, \leq)$ is a chain again. But by assumption (c) C then is finite. As any $C_k \subseteq C$ we find an increasing sequence in $\mathbb{N}$

$$\#C_0 \ \leq \ \#C_1 \ \leq \ \#C_2 \ \leq \ \ldots \ \leq \ \#C \ < \ \infty$$

As C contains finitely many elements, this sequence in $\mathbb{N}$ is bound and cannot rise indefinitely. Thus there is some $s \in \mathbb{N}$ such that $\#C_{s+i} = \#C_s$ for any $i \in \mathbb{N}$. And this is $C_{s+i} = C_s$ as we also have $C_s \subseteq C_{s+i}$ and these are finite sets.

To go full circle we need to prove (b) $\implies$ (a): We start by proving that $(X, \leq)$ satisfies ACC, as well. To do this consider an ascending sequence $x_0 \leq x_1 \leq x_2 \leq \ldots$ in X and denote $C_k := \{ x_0, x_1, \ldots, x_k \} \subseteq X$. Then clearly $C_k \in \mathcal{C}_0(X, \leq)$ and

$$C_0 \ \subseteq \ C_1 \ \subseteq \ C_2 \ \subseteq \ \ldots$$

is an ascending sequence in $\mathcal{C}_0(X,\leq)$. By assumption there is some $s \in \mathbb{N}$ such that for any $i \in \mathbb{N}$ we have $C_{s+i} = C_s$. That is $x_{s+i} \in C_{s+i} = C_s = \{ x_0, x_1, \ldots, x_s \}$ and thereby $x_{s+i} = x_k$ for some $k \in 0 \ldots s$. Then $x_{s+i} = x_k \leq x_s \leq x_{s+i}$ implies $x_{s+i} = x_s$. That is the sequence (x_k) stabilizes. For the DCC we consider $x_0 \geq x_1 \geq x_2 \geq \ldots$ in X again. With the same C_k as before we find $C_{s+i} = C_s$ again and thereby $x_{s+i} = x_k \geq x_s \geq x_{s+i}$. In complete analogy we get $x_{s+i} = x_s$ such that $(X,\leq)$ also satisfies the DCC.
It remains to prove that in this case any chain $C \in \mathcal{C}(X,\leq)$ can be refined to a maximal, finite chain in X. By (c) we know that $C = \{ x_1, \ldots, x_n \}$ is finite. Now let $\mathcal{A}$ be the set of all finite chains in X containing C

$$\mathcal{A} \;:=\; \{ D \in \mathcal{C}_0(X,\leq) \mid C \subseteq D \}$$

Then $\mathcal{A} \neq \emptyset$, as $C \in \mathcal{A}$. And by (b) $\mathcal{C}_0(X,\leq)$ satisfies the ACC, such that there is a maximal chain $C^* \in \mathcal{A}^*$. And if $D \in \mathcal{C}_0(X,\leq)$ satisfies $C^* \subseteq D$ then (as $C \subseteq C^*$) we have $D \in \mathcal{A}$, such that the maximality of C^* in $\mathcal{A}$ implies $C^* = D$. □

Proof of (0.27):
The proof is elementary, but makes use of the axiom of choice and is *very* intricate. For better readability we broke it down into several steps:

(0) If $X = \emptyset$ then $M = \emptyset$ is a chain (all elements of $\emptyset$ are comparable) that also is maximal (X does not have any other subsets). So the claim is satisfied trivially. From now on consider $X \neq \emptyset$:

(1) In a first step we will construct a function $\mathcal{C}(X,\leq) \to \mathcal{C}(X,\leq)$ that maps $C \mapsto C'$ where we have to construct C': To do this start with $\mathcal{A} := \mathcal{P}(X) \setminus \{ \emptyset \}$. Then $\mathcal{A} \neq \emptyset$, as $X \in \mathcal{A}$ and for the same reason we have $X \subseteq \bigcup \mathcal{A} \subseteq X$. Thus (by the axiom of choice) there is a choice function $r : \mathcal{A} \to X$ such that for any $A \in \mathcal{A}$ we have $r(A) \in A$. Given a chain $C \in \mathcal{C}(X,\leq)$, let us denote

$$C^+ \;:=\; \{ x \in X \setminus C \mid C \cup \{ x \} \in \mathcal{C}(X,\leq) \}$$

That is C^+ is the set of all elements, that can be appended to C without ruining its chain property. It may well be, that C^+ is empty - in fact we are looking for a a chain M with this property. If not, that is $C^+ \neq \emptyset$, then $C^+ \in \mathcal{A}$ and hence we may define

$$C' \;:=\; \begin{cases} C \text{ if } C^+ = \emptyset \\ C \cup \{ r(C^+) \} \text{ if } C^+ \neq \emptyset \end{cases}$$

In either case we have $C \subseteq C'$. And if $C \subset C'$ then the one elements that was appended, is $r(C^+) \in C^+$. This means that C' is a chain again and hence this function is well-defined.

(2) Fix any $x_0 \in X$ (this is possible, since $X \neq \emptyset$, according to step (0). Then $\{ x_0 \}$ is a chain of X, albeit a very short one.

$$\{ x_0 \} \;\in\; \mathcal{C}(X,\leq)$$

If $\mathcal{T} \subseteq \mathcal{C}(X,\leq) \subseteq \mathcal{P}(X)$ then $\mathcal{T}$ is partially ordered under inclusion $\subseteq$. Thus it makes sense to speak of chains (under $\subseteq$) of chains (under $\leq$) of X. I.e. we regard the set $\mathcal{C}(\mathcal{T},\subseteq) \subseteq \mathcal{P}(\mathcal{P}(X))$.

(3) **Definition:** As set of chains $\mathcal{T} \subseteq \mathcal{C}(X, \leq)$ will be said to be a **tower**, iff it satisfies all of the following three properties:

(T1) $\{ x_0 \} \in \mathcal{T}$

(T2) $\forall\, T \in \mathcal{T} \,:\, T' \in \mathcal{T}$

(T3) $\forall\, A \in \mathcal{C}(\mathcal{T}, \subseteq) \,:\, \mathcal{A} \neq \emptyset \implies \bigcup \mathcal{A} \in \mathcal{T}$

(4) For the fixed $x_0 \in X$ let us now define the following set of chains of X

$$\mathcal{T}_0 \;:= \{\, T \in \mathcal{C}(X, \leq) \mid x_0 \in T \,\}$$

We will now prove that $\mathcal{T}_0$ is a tower: As $\{ x_0 \}$ is a chain and $x_0 \in \{ x_0 \}$ we have (T1). If $T \in \mathcal{T}_0$ then $x_0 \in T \subseteq T'$ such that (T2) is satisfied, too. Now consider some $A \subseteq \mathcal{C}(\mathcal{T}_0, \subseteq)$ with $A \neq \emptyset$, then we need to prove $T := \bigcup A \in \mathcal{T}_0$. First we prove that $T \in \mathcal{C}(X, \leq)$ is a chain of X: That is any two elements $a, b \in T$ have to be comparable. By construction $a \in T$ means $a \in A$ for some $A \in \mathcal{A}$ and likewise $b \in B$ for some $B \in \mathcal{A}$. As $\mathcal{A}$ is a chain its elements A and B are comparable. Without loss of generality say $A \subseteq B$. Then $a \in A \subseteq B$ implies $a \in B$. But we also have $b \in B$ and as $B \in \mathcal{A} \subseteq \mathcal{T}_0 \subseteq \mathcal{C}(X, \leq)$ we see that $B \subseteq X$ is a chain in X. That is a and b are comparable. And as a and b have been arbitrary elements of T this means $T \in \mathcal{C}(X, \leq)$ is a chain itself. But as $A \in \mathcal{A} \subseteq \mathcal{T}_0$ we have $x_0 \in A$ by construction of $\mathcal{T}_0$. Hence we find $x_0 \in A \subseteq T$ such that $T \in \mathcal{T}_0$ which had to be shown for (T3).

(5) By (4) we know that towers are not a void notion, there is at least on of these. So we are tempted to look at the smalles tower possible

$$\mathcal{T}_* \;:= \bigcap \{\, \mathcal{T} \subseteq \mathcal{C}(X, \leq) \mid \mathcal{T} \text{ is a tower} \,\}$$

We will prove that $\mathcal{T}_*$ is a tower again: As for any tower $\mathcal{T}$ we have $\{ x_0 \} \in \mathcal{T}$ by (T1), we also have $\{ x_0 \} \in \mathcal{T}_*$. This is (T1) for $\mathcal{T}_*$. And if $T \in \mathcal{T}_*$ then $T \in \mathcal{T}$ for any tower $\mathcal{T}$. Thereby $T' \in \mathcal{T}$ again, for any tower $\mathcal{T}$ such that $T' \in \mathcal{T}_*$ as well. This is (T2) for $\mathcal{T}_*$. Finally take some $\mathcal{A} \in \mathcal{C}(\mathcal{T}_*, \subseteq)$ with $\mathcal{A} \neq \emptyset$ again and let $T := \bigcup \mathcal{A} \subseteq X$. That is $\mathcal{A} \subseteq \mathcal{T}_*$ is a chain. And for any tower $\mathcal{T}$ we have $\mathcal{A} \subseteq \mathcal{T}_* \subseteq \mathcal{T}$ such that $T \in \mathcal{T}$. As this is true for any tower we have $T \in \mathcal{T}_*$ which finally is (T3) for $\mathcal{T}_*$.

(6) Let $C \in \mathcal{T}_*$ be a chain that is comparable to any other chain, that is $C \subseteq T$ or $T \subseteq C$ for any other $T \in \mathcal{T}_*$. Then we define:

$$\mathcal{T}_C \;:= \; \left\{\, T \in \mathcal{T}_* \mid C' \subseteq T \text{ or } T \subseteq C \,\right\}$$

We will prove that $\mathcal{T}_C$ is another tower: As $\mathcal{T}_*$ is a tower we have $\{ x_0 \} \in \mathcal{T}_*$. And as $C \in \mathcal{T}_* \subseteq \mathcal{T}_0$ we have $x_0 \in C$ due to the construction of $\mathcal{T}_0$. Thus $\{ x_0 \} \subseteq C$ such that $\{ x_0 \} \in \mathcal{T}_C$. This is (T1) for $\mathcal{T}_C$. If now $T \in \mathcal{T}_C$ then we have to show $T' \in \mathcal{T}_C$ that is $C' \subseteq T'$ or $T' \subseteq T$. By assumption $T \in \mathcal{T}_C$ we have $C' \subseteq T$ or $T \subseteq C$. In the first case $C' \subseteq T \subseteq T$ we are done already. In the second case $T \subseteq C$ we need to recall our assumption on C: As $\mathcal{T}_*$ is a tower, we have $T' \in \mathcal{T}_*$ and thereby C is comparable with T'. We either have $C \subseteq T'$ or $T' \subseteq C$. The second case $T' \subseteq C$ is one of the good options, it yields $T' \in \mathcal{T}_C$ directly. Thus we are stuck with

$T \subseteq C$ and $C \subseteq T'$. As T' exceeds T by exactly one point $[T' = T \cup \{ x \}$ for $x = r(T^+) \in X]$ we either have $C = T$ or $C = T'$. The first is $C' = T'$ in particular $C' \subseteq T'$ and the second is $T' \subseteq C$ in particular. Thus in both cases we find $C' \subseteq \mathcal{T}_C$ again. Thus we have proved (T2) for $\mathcal{T}_C$. Let now $\mathcal{A} \subseteq \mathcal{T}_C$ with $\mathcal{A} \neq \emptyset$. In particular $\mathcal{A} \subseteq \mathcal{T}_*$ such that $T := \bigcup \mathcal{A} \in \mathcal{T}_*$, since $\mathcal{T}_*$ is a tower. By assumption on C it is comparable with any element $A \in \mathcal{A}$. If we have $A \subseteq C$ for any $A \in \mathcal{A}$ then $T = \bigcup A \subseteq C$ such that $T \in \mathcal{T}_C$. So let us now consider the case that there is some $B \in \mathcal{A}$ with $C \subseteq B$. As $B \in \mathcal{A} \subseteq \mathcal{T}_C$ we have $C' \subseteq B$ - the other option $B \subseteq C$ has been ruled out. In particular $C' \subseteq B \subseteq \bigcup \mathcal{A} = T$ such that we also have $T \in \mathcal{T}_C$ in this case. That is (T3) for $\mathcal{T}_C$

(7) Let us now introduce the following subset of $\mathcal{T}_*$ - it consist of all the elements of $\mathcal{T}_*$ that are comparable with every other element of $\mathcal{T}_*$

$$\mathcal{C}_* \;:=\; \{ A \in \mathcal{T}_* \mid \forall B \in \mathcal{T}_* : A \subseteq B \text{ or } B \subseteq A \}$$

We will now prove, that $\mathcal{C}_*$ is a tower, too: As $\mathcal{T}_*$ is a tower we have $\{ x_0 \} \in \mathcal{T}_*$. And if $T \in \mathcal{T}_*$ is any other element of $\mathcal{T}_* \subseteq \mathcal{T}_0$ we find $x_0 \in T$ due to the construction of $\mathcal{T}_0$. Thus $\{ x_0 \} \subseteq T$ and hence $\{ x_0 \}$ is comparable with all other $T \in \mathcal{T}_*$. This is $\{ x_0 \} \in \mathcal{C}_*$ and hence (T1) for $\mathcal{C}_*$. If now $C \in \mathcal{C}_*$ then $\mathcal{C}_C$ is a tower according to (6). In particular we have $\mathcal{T}_* \subseteq \mathcal{T}_C$ by construction of $\mathcal{T}_*$. But as also $\mathcal{T}_C \subseteq \mathcal{T}_*$ by construction of $\mathcal{T}_C$ this is $\mathcal{T}_C = \mathcal{T}_*$. That is for any $B \in \mathcal{T}_*$ we have $C' \subseteq B$ or $B \subseteq C \subseteq C'$. That is C' is comparable with any $B \in \mathcal{T}_*$ and hence $C' \in \mathcal{C}_*$ again. This is (T2) for $\mathcal{C}_*$. Let now $\mathcal{A} \subseteq \mathcal{C}_*$ with $\mathcal{A} \neq \emptyset$. In particular $\mathcal{A} \subseteq \mathcal{T}_*$ such that $T := \bigcup \mathcal{A} \in \mathcal{T}_*$, since $\mathcal{T}_*$ is a tower. Now consider any $B \in \mathcal{T}_*$ if $A \subseteq B$ for any $A \in \mathcal{A}$ then $T = \bigcup \mathcal{A} \subseteq B$ and hence T and B are comparable. If there is some $A \subseteq \mathcal{B}$ with $\neg(A \subseteq B)$ then we note that $A \in \mathcal{A} \subseteq \mathcal{C}_*$, that is A is comparable with *any* element of $\mathcal{T}_*$. And since $\neg(A \subseteq B)$ this only leaves $B \subseteq A$ for this particular $A \in \mathcal{A}$. Thus $B \subseteq A \subseteq \bigcup \mathcal{A} = T$. Thus B and T also are comparable in this case such that T is comparable with any $B \in \mathcal{T}_*$. But this is precisely what it takes for $T \in \mathcal{C}_*$. Thus we have proved (T3) for $\mathcal{C}_*$.

(8) Let us now reap the harvest of (7): Since $\mathcal{C}_*$ is a tower we have $\mathcal{T}_* \subseteq \mathcal{C}_*$ by construction of $\mathcal{T}_*$. But as $\mathcal{C}_* \subseteq \mathcal{T}_*$ has been a subset of $\mathcal{T}_*$ this is $\mathcal{C}_* = \mathcal{T}_*$. By construction of $\mathcal{C}_*$ this means that *every* element of $\mathcal{T}_*$ is comparable, that is $\mathcal{T}_*$ is totally ordered under $\subseteq$, we have

$$A \;\subseteq\; B \quad \text{or} \quad B \;\subseteq\; A$$

for any $A, B \in \mathcal{T}_*$. Finally define $M := \bigcup \mathcal{T}_*$ as we have just seen $\mathcal{T}_*$ is a chain itself, property (T3) of the tower $\mathcal{T}_*$ implies $M \in \mathcal{T}_*$ again. So by property (T2) we also have $M' \in \mathcal{T}_*$ such that $M' \subseteq \bigcup \mathcal{T}_* = M \subseteq M'$. So at long last we have $M' = M$. By construction of M' this is the case if and only if $M^+ = \emptyset$. So consider any $C \in \mathcal{C}(X, \leq)$ such that $M \subseteq C$. If there was some $x \in C \setminus M$ then $M \cup \{ x \} \subseteq C$ would be totally ordered, as it is a subset of the totally ordered set C. So we would have $x \in M^+ = \emptyset$ which is absurd. Hence we have $C = M$, which finally is the maximality of M.

□

Proof of (0.28):
By Hausdorff's maximum principle (0.27) Z has a maximal chain $M \subseteq Z$. By assumption (2) M has an upper bound $m \in Z$. That is we have $z \leq m$ for any $z \in M$. We will prove that m is a maximal element of Z: Suppose there was some $z \in Z$ with $m \leq z$. Then $M' := M \cup \{ z \}$ is a chain again: Given any $x, y \in M'$ we have four possibilities: (P1) $x, y \in M$, then x and y are comparable, as M is a chain; (P2) $x \in M$ but $y = z$ then $x \leq m \leq z$ such that $x \leq z = y$ are comparable; (P3) $x = z$ but $y \in M$ is analogous to (P2) and (P4) $x = z$ and $y = z$. Then $x = y$ trivially are comparable. In any case x and y are comparable and therefore $M' \subseteq Z$ is another chain in Z with $M \subseteq M'$. By maximality of M we have $M' = M$ which is $z \in M$. As m is an upper bound of M this implies $z \leq m$ and hence $z = m$. □

Proof of (0.30):
If $X = \emptyset$ then we may take $\leq := \emptyset \subseteq \emptyset \times \emptyset$ again. As X does not contain any non-empty subsets A, there is nothing to prove. So from now on we assume $X \neq \emptyset$. We will prove the theorem by *zornification* that is we define the set of all well-ordered subsets of X

$$\mathcal{Z} \;:=\; \{ (A, \leq_A) \mid A \subseteq X, \leq_A \text{ is a well ordering on } A \}$$

First note that $\mathcal{Z}$ is non-empty: Since $X \neq \emptyset$ there is some $x \in X$ and we may take $A := \{ x \}$. There is precisely one ordering on A and this is a well-ordering, namely $\leq_A = (x, x)$. We now introduce a partial order $\leq$ on $\mathcal{Z}$: If $(A, \leq_A)$ and $(B, \leq_B) \in \mathcal{Z}$ then we take $(A, \leq_A) \leq (B, \leq_B)$ if $A \subseteq B$ and $\leq_A$ is the restriction of $\leq_B$ to A and B only contains no smaller elements than A. Formally that are the following three properties

(1) $A \subseteq B$

(2) $\forall\, a, b \in A \;:\; \big(a \leq_A b \iff a \leq_B b\big)$

(3) $\forall\, a \in A, \forall\, b \in B \setminus A \;:\; a \leq_B b$

It is clear that this truly is a partial order on $\mathcal{Z}$. In order to apply the lemma of Zorn we need to prove, that any chain $\mathcal{C} \subseteq \mathcal{Z}$ has an upper bound. Our candidate is $(U, \leq_U)$, where

$$U \;:=\; \bigcup \{ C \mid (C, \leq_C) \in \mathcal{C} \}$$

as a subset of X. And for any $u, v \in U$ we define the relation $\leq_U$ by taking

$$x \leq_U y \quad :\iff \quad \exists\, (C, \leq_C) \in \mathcal{C} \;:\; u, v \in C \text{ and } u \leq_C v$$

We will now prove the following: For any $u, v \in U$ and any $(A, \leq_A) \in \mathcal{C}$ such that $u, v \in A$ we have the equivalence

$$u \leq_U v \quad \iff \quad u \leq_A v$$

If $\neg(u \leq_U v)$ then there is no $(C, \leq_C) \in \mathcal{C}$ such that $u, v \in C$ and $u \leq_C v$. But as $u, v \in A$ this must mean $\neg(u \leq_A v)$. Conversely if $u \leq_U v$ then there is some $(C, \leq_C) \in \mathcal{C}$ such that $u, v \in C$ and $u \leq_C v$. That is we have $u, v \in A \cap C$. As $\mathcal{C}$ is a chain we either have $(A, \leq_A) \leq (C, \leq_C)$ other the other way around. In this case we have $u, v \in A \subseteq C$ such that $u \leq_C v$ implies $u \leq_A v$ according to property (2). If conversely $(C, \leq_C) \leq (A, \leq_A)$ we still have $u, v \in C$ such that $u \leq_C v$ implies $u \leq_A v$ by property (2), as well.

Next we will verify that $\leq_U$ is a total order on U. If $u \in U$ then there is some $(C, \leq_C) \in \mathcal{C}$ such that $u \in C$. Thereby $u \leq_C u$ such that $u \leq_U u$ again. Now consider $u, v, w \in U$ such that $u \leq_U v$ and $v \leq_U w$. By construction this means that $u, v \in A$ for some $(A, \leq_A) \in \mathcal{C}$ and likewise $v, w \in B$ with $v \leq_B w$. As $\mathcal{C}$ is a chain we either have $(A, \leq_A) \leq (B, \leq_B)$ or the other way around. In this case we have $u \in A \subseteq B$ such that u, v and $w \in B$. Now $u \leq_A v$ implies $u \leq_B v$ and with $v \leq_B w$ this is $u \leq_B w$. Thereby $u \leq_U v$ again. And $(B, \leq_B) \leq (A, \leq_A)$ can be treated completely analogous. In particular for $u = w$ we have $u \leq_B v$ and $v \leq_B u$ imply $u = v$. So we also have the anti-symmetry $u \leq_U v$, $v \leq_U u \implies u = v$. To show that $\leq_U$ is total we finally pick up any $u, v \in U$. That is $u \in A$ and $v \in B$ for some $(A, \leq_A)$ and $(B, \leq_B) \in \mathcal{C}$. As $\mathcal{C}$ is a chain we may assume $(A, \leq_A) \leq (B, \leq_B)$ without loss on generality. Now $u \in A \subseteq B$ yields either $u \leq_B v$ or $v \leq_B u$. Accordingly we get $u \leq_U v$ or $v \leq_U u$ as needed.

In the next step we have to verify that $\leq_U$ is a well-ordering on U: That is we are given any non-empty subset $A \subseteq U$ and need to find a least element of this. Fix some $a \in A \subseteq U$ and take some $(C, \leq_C) \in \mathcal{C}$ such that $a \in C$. As $\leq_C$ is a well-ordering the set $A \cap C$ has a least element m. That is $m \in A \cap C$ and for any $b \in A \cap C$ we have $m \leq_C b$. If now $b \in A \subseteq U$ is any element in A, then there is some $(B, \leq_B) \in \mathcal{C}$ such that $b \in B$. We distinguish two cases: If $b \in C$ then $b \in A \cap C$ such that $m \leq_C b$ and thereby $m \leq_U b$. If $b \notin C$ then $b \in B \setminus C$. As $\mathcal{C}$ is totally ordered we have $(C, \leq_C) \leq (B, \leq_B)$ as the other relation would require $B \subseteq C$. Now note that $m \in C$ and $b \in B \setminus C$ imply $m \leq_B b$ by property (3). Again this is $m \leq_U b$. Thus A has a least element m.

By now we have $(U, \leq_U) \in \mathcal{Z}$ and we will show that for any $(A, \leq_A) \in \mathcal{C}$ we have $(A, \leq_A) \leq (U, \leq_U)$. First of all we have $A \subseteq U$ by construction of U. Also for any $a, b \in A$ we have seen $a \leq_A b \iff a \leq_U b$. So it remains to verify property (3): Consider any $a \in A$ and $b \in U \setminus A$, then we need to show $a \leq_U b$. But since $b \in U$ there is some $(B, \leq_B) \in \mathcal{C}$ such that $b \in B$. As $\mathcal{C}$ is a chain $(A, \leq_A)$ and $(B, \leq_B)$ are comparable. But $(B, \leq_B) \leq (A, \leq_A)$ cannot be due to $b \in B \setminus A$ we necessarily have $(A, \leq_A) \leq (B, \leq_B)$. From this we get $a \leq_B b$ which in turn is $a \leq_U b$. That is $(U, \leq_U)$ is an upper bound of $\mathcal{C}$.

By now we have proved that any chain $\mathcal{C} \subseteq \mathcal{Z}$ has an upper bound $(U, \leq_U)$. Thus by the lemma of Zorn (0.28) there is a maximal element $(M, \leq_M)$ in $\mathcal{Z}$. Suppose there was some $x \in X \setminus M$, then we would define $M' := M \cup \{ x \}$ and

$$\leq_{M'} \;:=\; \leq_M \;\cup \{ (m, x) \mid m \in M' \}$$

That is $\leq_{M'}$ is the order of M' that features $m \leq_{M'} x$ for any $m \in M$ and is just $\leq_M$ when restricted to M. By construction $(M', \leq_{M'})$ is a totally ordered set, such that $\leq_{M'}$ even is a well-ordering of M': If $A \subseteq M'$ then either $A \cap M \neq \emptyset$ or $A = \{ x \}$. In the first case the least element of $A \cap M$ is the least element of A, in the second case it is x. That is $(M', \leq_{M'}) \in \mathcal{Z}$ and $(M, \leq_M) \leq (M', \leq_{M'})$. But as $(M, \leq_M)$ is maximal, this means $M = M'$ which contradicts $x \in X \setminus M$. Thus we could not have chosen x in the first place, such that $X = M$. But therefore $\leq_M$ is a well ordering on X itself. □

Proof of (0.32):

(i) If X or $Y = \emptyset$, then there are neither functions $X \to Y$ nor functions $Y \to X$, as both would have to be subsets of $X \times Y = \emptyset$. Thus we have $X \neq \emptyset$ and $Y \neq \emptyset$. Now suppose $X \hookrightarrow Y$, that is we are given an injective function $f : X \hookrightarrow Y$. If we had $f(X) = Y$, then f would also be surjective, hence bijective, so $f^{-1} : Y \twoheadrightarrow X$ would already be the function we need. In case $B := f(X) \subset Y$ choose any $x_0 \in X$ and define $g : Y \to X$ by $g(y) := f^{-1}(y)$ for $y \in B$ and $g(y) := x_0$ for $y \in Y \setminus B$. Then $g(B) = f^{-1}(B) = X$, such that g is surjective.

Conversely if $Y \twoheadrightarrow X$ we are given a surjective function $g : Y \twoheadrightarrow X$. We define an equivalence relation on Y, by letting $y \sim y' :\Longleftrightarrow g(y) = g(y')$. Then $q : Y/\sim \to X : [y] \mapsto g(y)$ is well-defined and bijective: By definition $[y] = [y']$ is $y \sim y'$ which in turn is $g(y) = g(y')$. Therefore q is well-defined and injective. But it also is surjective: Given any $x \in X$ choose some $y \in Y$ with $g(y) = x$ - recall that g was assumed to be surjective. Then $q([y]) = g(y) = x$. But by the axiom of choice there is a set $B \subseteq Y$ such that the map $p : B \to Y/\sim : y \mapsto [y]$ is bijective, too. Therefore the map $qp : B \to X$ is bijective and hence $(qp)^{-1} : X \to B \subseteq Y$, as well. But this means, that $(qp)^{-1} : X \hookrightarrow Y$ is injective.

(ii) Let us take the set $\mathcal{Z} := \{ (A, f) \mid A \subseteq X, f : A \hookrightarrow Y \}$ of pairs of subsets $A \subseteq X$ and injective functions f from A into Y. As X and Y are non-empty, we may pick any two elements $x \in X$ and $y \in Y$ and define $A := \{ x \}$ and $f : A \to Y$ by $f(x) := y$. Then $(A, f) \in \mathcal{Z}$, such that this set is non-empty.

Also if (A, f) and $(B, g) \in \mathcal{Z}$, then we define a relation $\leq$ on $\mathcal{Z}$ by letting $(A, f) \leq (B, g)$ iff $A \subseteq B$ and $\forall\, a \in A : g(a) = f(a)$. Clearly $\leq$ is a partial order on $\mathcal{Z}$. Now consider any chain $(A_i, f_i) \subseteq \mathcal{Z}$ (where $i \in I$). Then we define

$$A := \bigcup_{i \in I} A_i$$

$$f : A \to Y : a \mapsto f_i(a) \text{ for any } i \in I \text{ with } a \in A_i$$

Let us check that f is well-defined: If $a \in A$ then there truly is some $i \in I$ with $a \in A_i$ by construction of A. And if $j \in I$ is any index with $a \in A_j$ then we have $A_i \subseteq A_j$ or $A_j \subseteq A_i$ as the chain is totally ordered. Then we also have $f_j(a) = f_i(a)$ or $f_i = f_j(a)$ by construction of $\leq$. But as $f_j(a) = f_i(a)$ it does not matter, which $j \in I$ with $a \in A_j$ we took. Also f is injective: Given any $a, b \in A$ with $f(a) = f(b)$, there are some $i, j \in I$ with $a \in A_i$ and $b \in A_j$. By interchanging we may assume $A_i \subseteq A_j$. Then, as also $a \in A_j$, we have $f(b) = f(a) = f_j(a) = f_i(a) = f(a)$. In particular $(A, f) \in \mathcal{Z}$ and $(A_i, f_i) \leq (A, f)$.

We have just argued, that any chain in $\mathcal{Z}$ has an upper bound such that we may invoke the lemma of Zorn (0.28) to find a maximal element (A^*, f^*) of $\mathcal{Z}$. We distinguish two cases: If $A^* = X$ then $f : X \hookrightarrow Y$ is injective itself. So let us deal with $A^* \subset X$ a proper subset. Suppose we had $f^*(A^*) \neq Y$, then there was some $y \in Y \setminus f^*(A^*)$. Also there is some $x \in X \setminus A^*$. Now take $B := A^* \cup \{ x \}$ and $g(b) := f^*(b)$ for $b \in A^*$ and $g(b) := y$ for $b = x$. Then $(A^*, f^*) < (B, g)$ in contradiction to the maximality of (A^*, f^*). From this contradiction we conclude $f^*(A^*) = Y$. Now, as $f^* : A^* \longleftrightarrow Y$ is bijective, we may take its inverse $Y \longleftrightarrow A^* \subseteq X$. This is the injective map $Y \hookrightarrow X$ we needed.

(iii) In case of (b) there is a bijective map $f : X \longleftrightarrow Y$. In particular $f : X \hookrightarrow Y$ is injective. But $f^{-1} : Y \hookrightarrow X$ is bijective (and hence injective), too, such that (a) follows immediately. If we start with (a) and need to prove (b) the story is a little more complicated:

By assumption there are some injective maps $f : X \hookrightarrow Y$ and $g : Y \hookrightarrow X$. Without loss of generality we may assume X and Y to be disjoint, if they are not, just look at $X' := \{1\} \times X$ and $Y' := \{2\} \times Y$ instead. For these sets it is clear, that $X' \cap Y' = \emptyset$ and that we have the obvious bijections $X \longleftrightarrow X' : x \mapsto (1, x)$ and $Y \longleftrightarrow Y' : y \mapsto (2, y)$. Thus the maps we would construct on X' and Y' can be transferred back to X and Y.

Let $Z := X \cup Y$ and remember: $X \cap Y = \emptyset$ by assumption. Starting with any $z \in Z$ we will define a sequence $(z_0, z_1, z_2, z_3, \dots)$ (that may or may not terminate) recursively. This sequence will always alternate, its elements will either be in $X \times Y \times X \times Y \times \dots$ or in $Y \times X \times Y \times X \times \dots$. We start with $z_0 := z$ and suppose we had already constructed $(z_0, \dots, z_n) \in Z^{n+1}$. Then we continue

- if $z_n \in f(X) \subseteq Y$, then we take $z_{n+1} := f^{-1}(z_n) \in X$
- if $z_n \in g(Y) \subseteq X$, then we take $z_{n+1} := g^{-1}(z_n) \in Y$
- if neither $z_n \in f(X)$ nor $z_n \in g(Y)$, then stop

We denote the chain generated by this algorithm, if we start with $z = z_0 \in Z$ will be denoted by $C(z)$. If $C(z)$ is finite, say $C(z) = (z_0, \dots, z_n)$, then we denote $\ell(z) := n \in \mathbb{N}$. Else, if the algorithm does not terminate at all, we say $\ell(z) := \infty$. Clearly this algorithm subdivides X in three separate parts:

$$\begin{aligned} X_1 &:= \{ x \in X \mid \ell(x) \in 1 + 2\mathbb{Z} \} \\ X_2 &:= \{ x \in X \mid \ell(x) \in 2\mathbb{Z} \} \\ X_\infty &:= \{ x \in X \mid \ell(x) = \infty \} \end{aligned}$$

Note that $x \in X_2$ means that the chain $C(x) = (z_0 = x, z_1, \dots, z_n)$ stops with some $z_n \in X \setminus g(Y)$. This can already happen at $n = 0$, namely if $x \notin g(Y)$. And likewise $x \in X_1$ means that $C(x)$ stops with some $z_n \in Y \setminus f(X)$. In particular $n \geq 1$ and hence $x \in g(Y)$. In exactly the same fashion we define the sets Y_1, Y_2 and $Y_\infty \subseteq Y$. By construction X and Y are the disjoint unions of these sets respectively

$$\begin{aligned} X &= X_1 \cup X_2 \cup X_\infty \\ Y &= Y_1 \cup Y_2 \cup Y_\infty \end{aligned}$$

The idea now lies in proving $f(X_2) = Y_1$ and $g(Y_2) = X_1$ and $f(X_\infty) = Y_\infty$. Then $X_2 \longleftrightarrow Y_1$ under f, $Y_2 \longleftrightarrow X_1$ under g and $X_\infty \longleftrightarrow Y_\infty$ under f, as these maps are injective. Thereby we can glue together a bijection $h : X \to Y$ by taking $h(x) := f(x)$ if $x \in X_2 \cap X_\infty$ and $h(x) := g^{-1}(x)$ for $x \in X_1$. And this is precisely what we need in (b).

So it remains to prove $f(X_2) = Y_1$ in a first step: Let us start with any $x \in X_2$, that is $C(x) = (x, y_1, x_2, \dots, y_n)$, where n is even (maybe 0). We need to show $y := f(x) \in Y_1$. So let the algorithm start in y: In the first step we have $y = \in f(x) \in f(X)$ and hence get $z_1 = f^{-1}(y) = x$.

That is the next element in the chain of y is x and from there on we know what will happen: $C(y) = (y, x, y_1, x_2, \dots, y_n)$. In particular $\ell(y) = n+1$ is odd and thereby $f(x) = y \in Y_1$. Conversely we start with some $y \in Y_1$ and need to find some $x \in X_2$ such that $f(x) = y$. As $y \in Y_1$ the chain that starts in y is of the form $C(y) = (y, x_1, y_2, \dots, x_n)$, where n is odd and in particular $n \geq 1$. That is, we have x_1, so what is it? By construction this means $y \in f(X)$ and $x_1 := f^{-1}(y)$. That is $y = f(x_1)$. Clearly $C(x_1) = (x_1, y_2, \dots, x_n)$ such that $\ell(x_1) = n-1$ is even. That is $x_1 \in X_2$ and thereby we have found an $x := x_1 \in X_2$ such that $y = f(x)$.

Of course we find $g(Y_2) = X_1$ in exactly the same manner. So it remains to prove $f(X_\infty) = Y_\infty$, but this is much the same, too: Consider any $x \in X_\infty$ and let $y := f(x)$. Then $C(y) = (y, x, \dots)$, as in the first step we have $y \in f(X)$ and thereby $z_1 = f^{-1}(y) = x$. Thus $C(y)$ does not terminate and hence $y \in Y_\infty$. Conversely again, given $y \in Y_\infty$ the chain $C(y) = (y, x_1, y_2, x_3, y_4, \dots)$ does not terminate. In particular x_1 is given by $x_1 = f^{-1}(y)$ and hence $y = f(x_1)$. Again $C(x_1) = x_1, y_2, x_3, y_4, \dots)$ does not terminate, making $x_1 \in X_\infty$.

Altogether we have established the equalities $f(X_2) = Y_1$, $g(Y_2) = X_1$ and $f(X_\infty) = Y_\infty$ and as X resp. Y are the disjoint unions of these subsets we can glue together a bijection h, as described above.

(vi) Let us prove $|X| = |X|$ for any set X. In case $X = \emptyset$ the symbol $|X| = |X|$ is true, by definition. And if $X \neq \emptyset$ then the identity $x \mapsto x$ is a bijective map on X. Thus we have $|X| = |X|$ in this case, too.

Next we prove $|X| \leq |Y|$ or $|X| \leq |Y|$: If $X = \emptyset$ then $|X| \leq |Y|$ and if $Y = \emptyset$, then $|Y| \leq |X|$. It remains to regard the case when both, X and Y, are non-empty. Then by assumption we have $X \hookrightarrow Y$ or $Y \hookrightarrow X$ by (ii) which is $|X| \leq |Y|$ or $|Y| \leq |X|$ respectively. Thus one of the two is always satisfied.

Now to $|X| \leq |Y|$ and $|Y| \leq |Z|$ implies $|X| \leq |Z|$: If we have $X = \emptyset$ then $|X| \leq |Z|$ is satisfied trivially. And if $Y = \emptyset$ then $X \hookrightarrow Y$ is false (there are no functions that target Y) such that we also have $X = \emptyset$, as well. And in this case $|X| \leq |Z|$ is satisfied trivially, again. So now suppose that both, X and Y, are non-empty. Then $|X| \leq |Y|$ turns into $f : X \hookrightarrow Y$ and $|Y| \leq |Z|$ turns into $g : Y \hookrightarrow Z$. for some injective f, g. Then the composition $gf : X \hookrightarrow Z$ also is injective, such that $|X| \leq |Z|$ is satisfied.

It remains to prove the anti-symmetry $|X| \leq |Y|$ and $|Y| \leq |X|$ implies $|X| = |Y|$: If $X = \emptyset$ then $|Y| \leq |X|$ implies $Y = \emptyset$, as above. In the same manner if $X = \emptyset$ then $|X| \leq |Y|$ implies $X = \emptyset$. But if $X = \emptyset = Y$, then $|X| = |Y|$ is satified trivially. So let us now assume X and Y to ne non-empty. Then $|X| \leq |Y|$ turns into $X \hookrightarrow Y$ and $|Y| \leq |X|$ turns into $Y \hookrightarrow X$. But then by (iii) we have just seen $X \longleftrightarrow Y$ which yields $|X| = |Y|$.

□

Proof of (0.35):

(i) In this easy case we are able to provide a bijective map s directly: That is we define $s : \mathbb{N} \to \mathbb{Z}$ and $\bar{s} : \mathbb{Z} \to \mathbb{N}$ and will prove that $\bar{s} = s^{-1}$ is the inverse map. In particular s is bijective and therefore $|\mathbb{N}| = |\mathbb{Z}|$. The following maps will do the trick

$$s \,:\, \mathbb{N} \to \mathbb{Z} \,:\, n \mapsto \begin{cases} n/2 \text{ if } n \text{ is even} \\ -(n+1)/2 \text{ if } n \text{ is odd} \end{cases}$$

$$\bar{s} \,:\, \mathbb{Z} \to \mathbb{N} \,:\, k \mapsto \begin{cases} 2k \text{ if } n \geq 0 \\ -(2k+1) \text{ if } k < 0 \end{cases}$$

Note that n is *even*, iff it is of the form $n = 2m$ for some $m \in \mathbb{N}$ and n is *odd* iff $n = 2m+1$ for some $m \in \mathbb{N}$. As we argued above, it suffices to show that $\bar{s} = s^{-1}$, we begin with $\bar{s}s(n) = n$ for any $n \in \mathbb{N}$: If n is even then $s(n) = n/2 \geq 0$ and thereby $\bar{s}s(n) = 2 \cdot (n/2) = n$. If n is odd, say $n = 2m+1$ then $s(n) = -(n+1)/2 = -(m+1) < 0$ and thereby $\bar{s}s(n) = -2k-1$ for $k = -(m+1)$. This is $2(m+1)-1 = 2m+1 = n$. Thus in both cases we have $\bar{s}s(n) = n$. We also have to prove $s\bar{s}(k) = k$ for any $k \in \mathbb{Z}$. For $k \geq 0$ we have $s\bar{s}(k) = s(2k) = 2k/2 = k$. Now let $k < 0$, say $k = -(m+1)$ where $m \in \mathbb{N}$, then we have $\bar{s}(k) = -2k-1 = 2(m+1)-1 = 2m+1$, which is an odd number and therefore $s\bar{s}(k) = -(2m+1+1)/2 = -(m+1) = k$. Again we have $s\bar{s}(k) = k$ in both cases and thereby $\bar{s} = s^{-1}$.

(ii) Let us split $\mathbb{N} \times \mathbb{N}$ into a sequence of finite sets: As any $(k,l) \in \mathbb{N}^2$ features finite k, l it is contained in a set of the form $B_n := \{\, (k,l) \in \mathbb{N}^2 \mid k \leq n, l \leq n \,\}$ for some $n \in \mathbb{N}$. And B_n is finite, as it contains exactly $(n+1)^2$ elements. Not let $A_0 := \{\, (0,0) \,\}$ and for any $n \geq 1$:

$$A_n \;:=\; B_n \setminus B_{n-1}$$

That is $A_1 = \{\, (0,1),(1,1),(1,0) \,\}$ and $A_2 = \{\, (0,2),(1,2),(2,2),(2,1),(2,0) \,\}$ and so on. In general $A_n = \{\, (k,n) \mid k \in 0 \ldots n \,\} \cup \{\, (n,k) \mid k \in 0 \ldots n \,\}$. That is

$$\#A_n \;=\; \#B_n - \#B_{n-1} \;=\; (n+1)^2 - n^2 \;=\; 2n+1$$

In particular we have $0 \ldots 2n \longleftrightarrow A_n$, that is we can enumerate the elements of A_n using $2n+1$ indices. Luckily $\mathbb{N}$ has space for infinitely many indices. Let $I_0 := \{0\}$ and for any $1 \leq n \in \mathbb{N}$ let I_n be the index set

$$I_n \;:=\; \left\{\, i \in \mathbb{N} \mid n^2 < i \leq (n+1)^2 \,\right\}$$

That is $\#I_n = (n+1)^2 - n^2 = \#A_n$ such that there is a bijection $b_n : I_n \longleftrightarrow A_n$. By construction it is clear, that the I_n for a partition of $\mathbb{N}$ and the A_n form a partition of $\mathbb{N}^2$. Hence we find a bijection between $\mathbb{N}$ and $\mathbb{N}^2$ by mapping the elements of I_n to A_n

$$\mathbb{N} \;=\; \bigcup_{n \in \mathbb{N}} I_n \;\longleftrightarrow\; \bigcup_{n \in \mathbb{N}} A_n \;=\; \mathbb{N}^2$$

(iii) For one it is clear, that $\mathbb{N} \hookrightarrow \mathbb{Q} : n \mapsto n/1$ is an injective map. Thus by Bernstein's equivalence theorem (0.32.(iii)) it suffices to find another surjective map $\mathbb{N} \twoheadrightarrow \mathbb{Q}$. We set out to construct such a map. Clearly

$$p \;:\; \mathbb{N} \times \mathbb{N} \;\twoheadrightarrow\; \left\{\, \frac{a}{b} \in \mathbb{Q} \;\middle|\; \frac{a}{b} \geq 0 \,\right\} \;:\; (a,b) \mapsto \frac{a}{b+1}$$

is surjective, as any $c/d \in \mathbb{Q}$ can be written as a/b for some $b \geq 1$: As $d \neq 0$ we either have $d \geq 1$ or $d \leq -1$ and in the latter case we can take $a := -c$ and $b := -d$. We then find another surjective map onto the negative rationals, in a similar fashion

$$q \ : \ \mathbb{N} \times \mathbb{N} \ \twoheadrightarrow \ \left\{ \frac{a}{b} \in \mathbb{Q} \ \middle| \ \frac{a}{b} \leq 0 \right\} \ : \ (a,b) \ \mapsto \ -\frac{a}{b+1}$$

Let us pick up any $t : \mathbb{N} \longleftrightarrow \mathbb{N} \times \mathbb{N}$, one of those bijective maps, that exist, according to (ii). Then we can present a map from $\mathbb{Z}$ to $\mathbb{Q}$ by letting

$$\mathbb{Z} \ \to \ \mathbb{Q} \ : \ k \ \mapsto \begin{cases} pt(k) \text{ if } k \geq 0 \\ qt(-k-1) \text{ if } k < 0 \end{cases}$$

Let us prove that this is surjective: Given any $a/b \in \mathbb{Q}$ we may assume $b \geq 1$. We then check whether $a/b \geq 0$: If this is the case, we have $p(a, b-1) = a/b$. And as t is bijective there is some $k \in \mathbb{N}$ with $t(k) = (a, b-1)$. Therefore $k \mapsto a/b$. Otherwise, if $a/b < 0$ $a < 0$ such that $-a \in \mathbb{N}$ and $q(-a, b-1) = a/b$. Again, as t is bijective, there is some $n \geq 1$ with $t(n-1) = (-a, b-1)$. And thereby we get $-n \mapsto qt(n-1) = q(-a, b-1) = a/b$. Thus this map reaches any $a/b \in \mathbb{Q}$ and thereby is surjective. But by (i) we can use this to get our surjective map

$$\mathbb{N} \ \longleftrightarrow \ \mathbb{Z} \ \twoheadrightarrow \ \mathbb{Q}$$

(iv) As Ω is countable, we have $|\Omega| \leq |\mathbb{N}|$. That is $\Omega \hookrightarrow \mathbb{N}$ or equivalently - by (0.32.(i)) - $\mathbb{N} \twoheadrightarrow \Omega$. That is there is a surjective map of the form $\omega : \mathbb{N} \twoheadrightarrow \Omega$. Also for any $i \in \Omega$ the set A_i is countable. If $A_i = \emptyset$, then we may ignore it, else there is a surjective mapping $\alpha(i) : \mathbb{N} \twoheadrightarrow A_i$.

By (ii) there also is a bijective map $\beta : \mathbb{N} \longleftrightarrow \mathbb{N} \times \mathbb{N}$. For any $n \in \mathbb{N}$ let us denote $\beta(n) = (\beta_1(n), \beta_2(n))$. We use all this to define a map of the form

$$s \ : \ \mathbb{N} \to \bigcup_{i \in \Omega} A_i \ : \ n \mapsto \alpha\big(\omega(\beta_1(n))\big)(\beta_2(n))$$

That is the first entry of $\beta(n)$ is used to choose the set A_i to pick from and the second entry of $\beta(n)$ is used to pick an element. Therefore s is surjective: Consider any $a_i \in A_i$, as $i \in \Omega$ there is some $k \in \mathbb{N}$ with $i = \omega(k)$. And as $a_i \in A_i$ there is some $l \in \mathbb{N}$ with $a_i = \alpha(i)(l)$. Now choose $n \in \mathbb{N}$ with $\beta(n) = (k, l)$, that is $i = \omega(k) = \omega(\beta_1(n))$ and $a_i = \alpha(i)(l) = \alpha(i)\beta_2(n))$. Together this is $a_i = s(n)$ and as we can do this for any $i \in \Omega$ and any $a_i \in A_i$ the map s is surjective. But $\mathbb{N} \twoheadrightarrow \bigcup_i A_i$ means, that the union is countable, again.

(v) The map $X \hookrightarrow \mathcal{P}(X) : x \mapsto \{ x \}$ obviously is injective, such that $|X| \leq |\mathcal{P}(X)|$. And if we consider any function $f : X \to \mathcal{P}(X)$, then we will show that f cannot be surjective: As $f(x)$ is a subset of X it makes sense, to define the following subset

$$R \ := \ \{ x \in X \mid x \notin f(x) \} \ \in \ \mathcal{P}(X)$$

Suppose there was some $r \in X$ with $f(r) = R$, then we raise the question: Is $r \in R$? Suppose we had $r \in R = f(r)$ then by construction of R we had $r \notin R$, a contradiction. Suppose we had $r \notin R$, then $r \notin f(r)$ was false and hence $r \in f(r) = R$, a contradicition, again. Either way the coin lands, we arrive at a contradiction and this means there is no $r \in X$ with $f(r) = R$. In other words, f is *not* surjective. Thus we cannot have $|X| = |\mathcal{P}(X)|$ and this is summarized in $|X| < |\mathcal{P}(X)|$.

□

Proof of (0.36):
Abbreviate $A := \bigcup \mathcal{A}$ and $B := \bigcup \mathcal{B}$ the grand union, respectively. If $a \in A$ then there is some $i \in I$ with $a \in A_i$. And as the A_i are pairwise distinct, this i even is uniquely determined. Also there is a bijective map $\mathfrak{a}_i : A_i \longleftrightarrow B_{\beta(i)}$ by assumption. Thus we get a well-defined map, by letting

$$\alpha \ : \ A \ \to \ B \ : \ a \ \mapsto \ \alpha_i(a) \text{ where } a \in A_i$$

This map is injective: Suppose $\alpha(a_i) = \alpha(a_j)$ where $a_i \in A_i$ and $a_j \in \forall_j$. By construction this means $\alpha_i(a_i) = \alpha_j(a_j) \in B_k$ for some $k \in K$. By construction of α_i this k is $k = \beta(i)$ and likewise $k = \beta(j)$. But as β is injective, $\beta(i) = \beta(j)$ implies $i = j$. But α_i is injective, as well and hence $\alpha_i(a_i) = \alpha_i(a_j)$ implies $a_i = a_j$. But α also is surjective: Given any $b \in B$ there is some (uniquely determined) $k \in K$, such that $b \in B_k$. Let $i := \beta^{-1}(k)$ and $a := \alpha_i^{-1}(b)$, then $a \in A_i$ and thereby $\alpha(a) = \alpha_i(a) = b$ is clear. That is α is bijective and hence we gain the equality of the cardinalities. □

Proof of (0.38):

(i) For a set $\mathcal{P} \subseteq \mathcal{P}(X)$ of subsets of X let us abbreviate the following properties: (1) $\mathcal{P} \neq \emptyset$, (2) any $P \in \mathcal{P}$ is countably infinite and (3) for any $P, Q \in \mathcal{P}$ with $P \neq Q$ we have $P \cap Q = \emptyset$. Then we define the following set:

$$\mathcal{Z} \ := \ \{ \mathcal{P} \subseteq \mathcal{P}(X) \mid \text{(1), (2) and (3)} \}$$

As X is infinite, we have $\mathbb{N} \hookrightarrow X$ and thereby X contains some countably infinite subset $P := \{ x_n \mid n \in \mathbb{N} \} \subseteq X$. Thereby $\mathcal{P} := \{ P \}$ satisfies (1) to (3) and thereby $\mathcal{Z} \neq \emptyset$. Clearly $\mathcal{Z}$ is partially ordered under inclusion "$\subseteq$". And if $(\mathcal{C}_i) \subseteq \mathcal{Z}$ is a chain in $\mathcal{Z}$ (where $i \in I$), then the union $\bigcup_i \mathcal{C}_i$ is an element of $\mathcal{Z}$ again: Properties (1) and (2) are obvious and for (3) we consider any $P \in \mathcal{C}_i$ and $Q \in \mathcal{C}_j$. As the $\mathcal{C}_i$ form a chain, we may assume $\mathcal{C}_i \subseteq \mathcal{C}_j$ without loss of generality. Then $P \in \mathcal{C}_j$ is true, as well. Thus if $P \neq Q$ then $P \cap Q = \emptyset$ by (3) of $\mathcal{C}_j$ and hence we have (3) for $\bigcup_i \mathcal{C}_i$ too. Thus by the lemma of Zorn (0.28) or remark (2.1.(ix)) there is a maximal element $\mathcal{M} \in \mathbb{Z}$. We now claim, that

$$B \ = \ X \setminus \bigcup \mathcal{M}$$

is a finite set: Suppose not, that is B is infinite and thereby there is some $\mathbb{N} \hookrightarrow B$, in other words $A = \{ x_n \mid n \in \mathbb{N} \} \subseteq B$. Thereby $A \subseteq X$ and thus $\mathcal{M} \cup \{ A \}$ satisfies (1) to (3) again. As before (1) and (3) are clear and for (3) we regard any $P, Q \in \mathcal{M} \cup \{ A \}$ with $P \neq Q$. If both $P, Q \in \mathcal{M}$, then $P \cap Q = \emptyset$ by (3) of $\mathcal{M}$, so we may assume $P \in \mathcal{M}$ and $Q = A$. Then $P \in \mathcal{M}$ implies $P \subseteq \bigcup \mathcal{M} = X \setminus B$ and then $Q = A \subseteq B$ yields $P \cap Q = \emptyset$. Thus we have $\mathcal{M} \subset \mathcal{M} \cup \{ A \} \in \mathcal{Z}$ in contradiction to the maximality of $\mathcal{M}$ and this means B must be finite. Let us now construct a suitable $\mathcal{P}$ out of $\mathcal{M}$ and B: Choose any $Q \in \mathcal{M}$ and replace Q with $Q \cup B$, that is

$$\mathcal{P} \;:=\; \big(\mathcal{M} \setminus \{\, Q \,\}\big) \cup \{\, Q \cup B \,\}$$

Then $Q \cup B$ clearly is countable again, so $\mathcal{P}$ satisfies (2). Also $\mathcal{P}$ satisfies (3), that is the elements of $\mathcal{P}$ are pairwise disjoint and finally X is the grand union of $\mathcal{P}$, as $\bigcup \mathcal{P} = \bigcup \mathcal{M} \cup B = (X \setminus B) \cup B = X$. Thus $\mathcal{P}$ is a partition of X consisting of countable sets, only.

(ii) By (i) there is a partition $\mathcal{P} = \{\, P_i \mid i \in I \,\}$ of X, such that any P_i is countably infinite. Let $P_i := \{\, x_{i,k} \mid k \in \mathbb{N} \,\}$, the trick is to decompose $\mathbb{N}$ into the subsets $k - 1 + n\mathbb{N} \subseteq \mathbb{N}$. For $k = 1$ this is $n\mathbb{N} = \{\, nk \mid k \in \mathbb{N} \,\}$ up to $n - 1 + n\mathbb{N} = \{\, (n-1) + nk \mid k \in \mathbb{N} \,\}$. This partition can be used to partition P_i into n distinct subsets

$$A_{i,j} \;:=\; \{\, x_{i,k} \mid k \in (j-1) + n\mathbb{N} \,\}$$

The sets $\{\, A_{i,1}, \ldots, A_{i,n} \,\}$ inherit being a partition of P_i from the sets $\{\, n\mathbb{N}, \ldots, (n-1) + n\mathbb{N} \,\}$, that partition $\mathbb{N}$. Also any $A_{i,j}$ is countably infinite by construction and thereby $|P_i| = |A_{i,j}|$ under the bijection $x_{i,k} \mapsto x_{i,(j-1)+nk}$. And from this it is clear that $A_1, \ldots, A_n$ partition X, where

$$A_j \;:=\; \bigcup_{i \in I} A_{i,j}$$

That is we have properties (1) and (2) for these sets. The third property $|X| = |A_j|$ is inherited from $|P_i| = |A_{i,j}|$ using proposition (0.36), as both unions run over $i \in I$.

(iii) Let us start with (a) $\implies$ (b): As X is infinite there is $\mathbb{N} \hookrightarrow X$ such that X has a countably infinite subset $C = \{\, x_n \mid n \in \mathbb{N} \,\} \subseteq X$. And if $m := \#F \in \mathbb{N}$, then we write F in the form $F = \{\, f_0, \ldots, f_{m-1} \,\}$. Then we are able to define a map, that obviously is bijective

$$X \longleftrightarrow X \cup F \;:\; x \mapsto \begin{cases} f_k \text{ if } x = x_k \text{ where } k < m \\ x_{k-m} \text{ if } x = x_k \text{ where } k \geq m \\ x \text{ if } x \notin C \end{cases}$$

Conversely for (b) $\implies$ (a) we use proof by contradiction: Suppose X *was* finite, say $n := \#X$ and $X = \{\, x_1, \ldots, x_n \,\}$. Then we pick up any set F that contains an element, not contained in X before, e.g. $F := \{\, X \,\}$. Then $F \cap X \neq \emptyset$ would mean $X \in X$ which is not allowed, for sets. Then $X \cup F$ would contain $n+1$ elements, as we get a bijection $1 \ldots (n+1) \to X$ by $k \mapsto x_k$ and $n+1 \mapsto X$. Thus (b) was false, too.

- For (c) $\implies$ (a) proof by contradiction works, as well: Again suppose X *was* finite. Then we could choose $F := X$ and thereby get $X \setminus F = \emptyset$. Yet $X \neq \emptyset$ by assumption and thereby $|X|$ and $|X \setminus F|$ are not the same. Conversely for (a) $\implies$ (c) we use induction on the number $n := \#(X \cap F)$ of elements in $X \cap F$. For $n = 0$ we have $X \cap F = \emptyset$ and thereby $X \setminus F = X \setminus (X \cap F) = X \setminus \emptyset = X$. In particular $|X| = |X \setminus F|$. Now for the induction step $n \geq 1$ we consider $X \cap F = \{\, f_1, \ldots, f_n \,\}$. By induction hypothesis, we have $X \longleftrightarrow X' := X \setminus \{\, f_2, \ldots, f_n \,\}$. Then $X \setminus F = X \setminus \{\, f_1, \ldots, f_n \,\} = X' \setminus \{\, f_1 \,\}$. And as X' is infinite (X is infinite and has the same cardinality) there is a countably infinite set $C \subseteq X'$. Without loss of generality we may assume $f_1 \notin C$, if we had $f_1 \in C$ then we could simply take to $C \setminus \{\, f_1 \,\}$, which countably infinite again

- just like $\mathbb{N} \setminus \{0\}$. Let $C = \{ x_k \mid k \in \mathbb{N} \} \subseteq X'$ where $f_1 \notin C$. Using this we can define a map, that obviously is bijective

$$X' \longleftrightarrow X' \setminus \{ f_1 \} \; : \; x \mapsto \begin{cases} x_0 \text{ if } x = f_1 \\ x_{k+1} \text{ if } x = x_k \\ x \text{ if } x \notin C, x \neq f_1 \end{cases}$$

Then we get $X \longleftrightarrow X' \longleftrightarrow X' \setminus \{ f_1 \} = X \setminus \{ f_1, \ldots, f_n \} = X \setminus F$. So if we compare X from the left hand side to $X \setminus F$ from the right hand side, we see $X \longleftrightarrow X \setminus F$ which is $|X| = |X \setminus F|$.

- The direction (a) $\implies$ (b) is surprisingly easy: Let us first regard the case $A = X$ and note that we can realize $X \sqcup X$ as $X_1 \cup X_2$ where $X_1 := \{ 1 \} \times X$ and $X_2 := \{ 2 \} \times X$. Next we use (ii) to get a partition $X = A \cup B$ of the infinite set X where $|X| = |A| = |B|$. That is there are bijective maps $f : A \longleftrightarrow X$ and $g : B \longleftrightarrow X$. These can be used to get a bijection

$$X = A \cup B \longleftrightarrow X \sqcup X \; : \; x \mapsto \begin{cases} (1, f(x)) \text{ if } x \in A \\ (2, g(x)) \text{ if } x \in B \end{cases}$$

Now for a general subset $A \subseteq X$ it is clear, that there is an injection of the form $A \sqcup X \hookrightarrow X \sqcup X$ by taking $(A, a) \mapsto (1, a) \in X_1$ and $(X, x) \mapsto (2, x) \in X_2$. Conversely there is an obvious injection of the form $X \hookrightarrow A \sqcup X$ given by $x \mapsto (X, x)$. Combining these, we get

$$A \sqcup X \hookrightarrow X \sqcup X \longleftrightarrow X \hookrightarrow A \sqcup X$$

And from $A \sqcup X \hookrightarrow X$ and $X \hookrightarrow A \sqcup X$ we conclude $A \sqcup X \longleftrightarrow X$ using Bernstein's equivalence theorem (0.32.(iii)). Conversely, for (d) $\implies$ (a) we assume X was finite, say $\#X = n$. Then $X \sqcup X$ is two copies of X and hence a finite set with $\#(X \sqcup X) = 2n$. As $n < 2n$ for $n \geq 1$ there can be no bijection between X and $X \sqcup X$, in contradiction to (d).

(iv) The only hard part is (a) $\implies$ (b) so let's get over it: We aim for a zornification, so let us define the following set, consisting of subsets $A \subseteq X$ equipped with a bijection $\beta : A \longleftrightarrow A \times A$

$$\mathcal{Z} \; := \; \{ (A, \beta) \mid A \subseteq X, \; \beta : A \longleftrightarrow A \times A \}$$

This set is non-empty: As X is infinite there is countably infinite subset $\mathbb{N} \longleftrightarrow A \subseteq X$. And as $\mathbb{N} \longleftrightarrow \mathbb{N} \times \mathbb{N}$ by (0.35.(ii)) this installs a bijection $\beta : A \longleftrightarrow A \times A$. Thus $(A, \beta) \in \mathcal{Z}$ such that $\mathcal{Z}$ is non-empty, it even contains some (A, β) with infinite set A. This set is partially ordered under the relation $(A, \alpha) \leq (B, \beta)$ iff $A \subseteq B$ and for any $a \in A$ we get $\alpha(a) = \beta(a)$. Now if $(A_i, \beta_i) \subseteq \mathcal{Z}$ is a chain in $\mathcal{Z}$ then we can take

$$A := \bigcup_{i \in I} A_i \quad \text{and} \quad \beta(a) := \beta_i(a) \text{ for any } i \in I \text{ with } a \in A_i$$

This is well-defined, as whenever $(A_i, \beta_i) \leq (A_j, \beta_j)$ and $a \in A_i$ then the functions $\beta_j(a) = \beta_i(a)$ agree by construction. And if $\beta(a) = \beta(b)$ for some $a \in A_i$ and $b \in A_j$ then we may assume $A_i \subseteq A_j$ and thereby $a \in A_j$. Then $\beta_j(a) = \beta_i(a) = \beta(a) = \beta(b) = \beta_j(b)$ implies $a = b$, as β_j is

injective. Given any $(a,b) \in A \times A$ we have $a \in A_i$ and $b \in A_j$ again. Again we assume $A_i \subseteq A_j$ and thereby $a \in A_j$ and find $\beta : \beta_j^{-1}(a,b) \mapsto (a,b)$, which also is the surjectivity of β. Altogether $(A,\beta) \in \mathcal{Z}$ is an upper bound of the chain (A_i,β_i). Thus by the lemma of Zorn (0.28), there is a maximal element $(M,\beta) \in \mathcal{Z}$. As we have seen above, that M is an infinite set, here.

Now that we've got a maximal element (M,β) let us regard $B := X \setminus M$. In the next step we will prove that $|B| < |M|$. Suppose there was some injective map $M \hookrightarrow B$, that is $\mu : M \longleftrightarrow A \subseteq B$ maps M onto a subset A of B bijectively. Note that $M \cap A = \emptyset$ are disjoint, as $M \subseteq X \setminus B$ and $A \subseteq B$. We now split $(M \cup A) \times (M \cup A)$ into 4 separate parts

	M	A
M	$M \times M$	$M \times A$
A	$A \times M$	$A \times A$

And we use (ii) for $n = 3$ to split A into 3 separate copies $A = A_1 \cup A_2 \cup A_3$. For any $i \in 1 \ldots 3$ let $\alpha_i : A_i \longleftrightarrow A$ be the bijective maps, we've got. Then we can build up the chain of bijections

$$A_1 \longleftrightarrow A \longleftrightarrow M \longleftrightarrow M \times M \longleftrightarrow A \times A$$

that is $(\mu \times \mu)\beta\mu^{-1}\alpha_1 : A_1 \longleftrightarrow A \times A$. In much the same way we find the bijection $(\mathbb{1}_M \times \mu)\beta\mu^{-1}\alpha_2$ of the sets $A_2 \longleftrightarrow M \times A$ and $(\mu \times \mathbb{1}_M)\beta\mu^{-1}\alpha_3$ of the sets $A_3 \longleftrightarrow A \times M$ by composing

$$A_2 \longleftrightarrow A \longleftrightarrow M \longleftrightarrow M \times M \longleftrightarrow M \times A$$

$$A_3 \longleftrightarrow A \longleftrightarrow M \longleftrightarrow M \times M \longleftrightarrow A \times M$$

We that is we can assign the 4 parts of $M \cup A = M \cup A_1 \cup A_2 \cup A_3$ to the 4 parts of $(M \cup A) \times (M \cup A)$. Using (0.36) this can be patched together into a single bijection

$$\begin{aligned} M \cup A &= M \cup A_1 \cup A_2 \cup A_3 \\ &\longleftrightarrow (M \times M) \cup (A \times A) \cup (M \times A) \cup (A \times M) \\ &= (M \cup A) \times (M \cup A) \end{aligned}$$

Note that the first patch $M \longleftrightarrow M \times M$ is β and hence we have found an extension $(M \cup A, \overline{\beta})$ of (M,β). But this is in contradiction to the maximality of (M,β) and hence could not have been the case. That is we have to discard the assumption $|M| \leq |B|$. As comparing cardinalities is a total order, by (0.32.(ii)), we conclude $|B| < |M|$. That is we can inject $\lambda : B \longleftrightarrow L \subseteq M$ onto some subset L of M. And thereby, by the (d) part of (iii) we get

$$X = B \cup M \longleftrightarrow L \sqcup M \longleftrightarrow M$$

That is we have a bijection $\xi : M \longleftrightarrow X$ and this can be used to compose the bijection $(\xi \times \xi)\mu\xi^{-1}$ of the sets $X \longleftrightarrow X \times X$. That is we compose the chain

$$X \longleftrightarrow M \longleftrightarrow M \times M \longleftrightarrow X \times X$$

- The other implications are easy: For (b) $\implies$ (d) we use induction on n: The case $n = 1$ is obvious, as $\mathbb{1} : X \longleftrightarrow X = X^1$ is a bijection. So by induction hypothesis there is a bijective map $\delta : X^n \longleftrightarrow X$. And by hypothesis (b) there also is a bijection $\beta : X^2 \longleftrightarrow X$. As also $\alpha : X^{n+1} \longleftrightarrow X^n \times X$ under $(x_1, \ldots, x_{n+1}) \mapsto ((x_1, \ldots, x_n), x_{n+1})$ we can compose these maps to find a bijection

$$X^{n+1} \longleftrightarrow X^n \times X \longleftrightarrow X \longleftrightarrow X$$

given by $\beta(\delta \times \mathbb{1}_X)\alpha : X^{n+1} \longleftrightarrow X$. This is the induction step and thereby (d). Now (d) $\implies$ (c) is trivial, by taking $x = 2$. It remains to return (c) $\implies$ (a): As always we suppose X was finite, by assumption we have $k := \#X \geq 2$. Then it is clear, that X^n is a finite set, too with $\#X^n = k^n$ elements. But as $n \geq 2$ and $k \geq 2$ we have $1 < k < k^{n-1}$ and thereby $k < k^n$. That is property (c), which reads as $k = |X| = |X^n| = k^n$, could not have been true.

- Let us now prove (a) $\implies$ (c): As X is infinite, there is a bijection $d_n : X \longleftrightarrow X^n$ for any $n \geq 1$, according to (iv). This can be used to construct a bijection of the following form

$$X \times \mathbb{N} \longleftrightarrow \bigcup_{n=1}^{\infty} X^n \; : \; (x, n) \mapsto d_n(x)$$

This map clearly is well-defined and injective: If $d_m(x) = d_n(y)$ then the lengths of the tuples $m = n$ must be equal and as d_n is injective, we also get $x = y$. Also if $(x_1, \ldots, x_n) \in X^n$ is any n-tuple, there is some $x \in X$ such that $d_n(x) = (x_1, \ldots, x_n)$, thus $(x, n) \mapsto (x_1, \ldots, x_n)$. That is the surjectivity of the above map. Also by (a) $\implies$ (b) there is a bijection $X \longleftrightarrow X \times \mathbb{N}$. Let us concatenate these bijections, then we read the claim from

$$X \longleftrightarrow X \times \mathbb{N} \longleftrightarrow \bigcup_{n=1}^{\infty} X^n$$

- Next in line is (c) $\implies$ (d): It is clear that $X \hookrightarrow \Omega(X) \setminus \{\emptyset\}$ defined by $x \mapsto \{x\}$ is an injective map. But we also get a surjective map of the following form

$$\bigcup_{n=1}^{\infty} X^n \twoheadrightarrow \Omega(X) \setminus \{\emptyset\} \; : \; (x_1, \ldots, x_n) \mapsto \{x_1, \ldots, x_n\}$$

That is we also have a surjection $X \longleftrightarrow \bigcup_n X^n \twoheadrightarrow \Omega(X) \setminus \{\emptyset\}$. By the Bernstein equivalence theorem (0.32.(iii)), this is $X \longleftrightarrow \Omega(X) \setminus \{\emptyset\}$. In particular $\Omega(X) \setminus \{\emptyset\}$ is an infinite set, as X is and by property (b) in (iii) this means

$$|X| \; = \; |\Omega(X) \setminus \{\emptyset\}| \; = \; |\big(\Omega(X) \setminus \{\emptyset\}\big) \cup \{\emptyset\}| \; = \; |\Omega(X)|$$

- Time to close the circle by proving (d) $\implies$ (a): Suppose X was finite, say $X = \{x_1, \ldots, x_n\}$. Then $\mathcal{O}(X) = \mathcal{P}(X)$, as any subset $A \subseteq X$, is finite, too. Then there is a bijection

$$\mathbb{B}^n \longleftrightarrow \mathcal{P}(X) \; : \; (b_1, \ldots, b_n) \mapsto \{x_k \mid b_k = 1\}$$

As $\mathbb{B} = \{0,1\}$ has two elements, we see $\#\mathbb{B}^n = 2^n$ where $n = \#X$ and thereby $\mathcal{P}(X) = 2^n$. But as $n < 2^n$ for any $n \geq 1$ we find that X and $\mathcal{P}(X) = \Omega(X)$ cannot have the same cardinality, in contradiction to (d). Alternatively, we could argue: As X is finite we get $\mathcal{O}(X) = \mathcal{P}(X)$. But by (0.35.(v)) we have $|X| < |\mathcal{P}(X)|$, which contradicts (d).

(vi) By (0.32.(ii)) we have $X \hookrightarrow Y$ or $Y \hookrightarrow X$. As $X \sqcup Y$ and $Y \sqcup X$ obviously have the same cardinality, we may assume $X \hookrightarrow Y$ without loss of generality, therefore we have to prove $|X \sqcup Y| = |Y|$. As $X \hookrightarrow Y$ there is a subset $U \subseteq Y$ with $X \longleftrightarrow U$. Then by property (d) in (iii) we have already have the claim $|X \sqcup Y| = |U \sqcup Y| = |Y|$.

- As above we may assume $X \subseteq Y$, and as $X \neq \emptyset$ we may fix any $x \in X$ and thereby get an injective map $Y \hookrightarrow X \times Y : y \mapsto (x,y)$. In particular $|Y| \leq |X \times Y|$. On the other hand, if $\iota : X \hookrightarrow Y$ is the injection, this induces $X \times Y \hookrightarrow Y \times Y : (x,y) \mapsto (\iota(x),y)$. But then by property (b) of of (iv) we get the second claim $|X \times Y| \leq |Y \times Y| = |Y|$, too.

(vii) First of all, we can omit any $i \in I$ with $A_i = \emptyset$, as these do not contribute to the union of the A_i. That is it suffices to regard $I_0 := \{\, i \in I \mid A_i \neq \emptyset \,\}$. As the remaining A_i are countable, they are of the form $A_i = \{\, a(i,n) \mid n \geq 1 \,\}$. Now define $A_n := \{\, a(i,n) \mid i \in I_0 \,\}$, then we get

$$A \;:=\; \bigcup_{i \in I} A_i \;=\; \bigcup_{n=1}^{\infty} A_n$$

As $|I| \leq |X|$ there is some injective map $I \hookrightarrow X$ and thereby I_0 corresponds $I_0 \longleftrightarrow X_0$ to a subset $X_0 \subseteq X$, that is X_0 is of the form $X_0 = \{\, x_i \mid i \in I_0 \,\}$. In particular, if we fix any $i_0 \in I_0$, we find a surjective map

$$X \;\twoheadrightarrow\; I_0 \;:\; x \mapsto \begin{cases} i \text{ if } x = x_i \\ i_0 \text{ if } x \notin X_0 \end{cases}$$

and this can be used to create another surjective map $X \twoheadrightarrow A_n : x_i \mapsto a(i,n)$. For any $n \geq 1$ let $X_n := X$ be a copy of X. Then it is clear that the following map is another surjection

$$\bigcup_{n=1}^{\infty} X^n \;\twoheadrightarrow\; \bigsqcup_{n=1}^{\infty} X_n \;:\; (x_1, \ldots, x_n) \mapsto (n, x_n)$$

By what we have argued above, any $X_n = X$ maps surjectively onto A_n and thereby we also have the following surjective map

$$\bigsqcup_{n=1}^{\infty} X_n \;\twoheadrightarrow\; \bigsqcup_{n=1}^{\infty} A_n \;:\; (n, x_n) \mapsto \begin{cases} a(i,n) \text{ if } x_n = x_i \\ a(i_0,n) \text{ if } x \notin X_0 \end{cases}$$

By property (c) in (v) we have a bijection between X and the union $\bigcup_n X_n$ so we can use this to compose the following chain of surjections, that proves the claim

$$X \;\longleftrightarrow\; \bigcup_{n=1}^{\infty} X^n \;\twoheadrightarrow\; \bigsqcup_{n=1}^{\infty} X_n \;\twoheadrightarrow\; \bigsqcup_{n=1}^{\infty} A_n \;\twoheadrightarrow\; \bigcup_{n=1}^{\infty} A_n \;=\; A$$

□

Proof of (9.4):

(i) Clearly for any $x \in X$ we have $x \sim x$, since $x = ex$. Also if $x \sim y$, say $y = gx$ for some $g \in G$, then $x = ex = (g^{-1}g)x = g^{-1}(gx) = g^{-1}y$ such that we also have $y \sim x$. And if also $y \sim z$, say $z = hy$ for some $h \in G$, then we also have $z = hy = h(gx) = (hg)x$ such that $x \sim z$. Altogether $\sim$ is an equivalence relation on X. And for $x \in X$ the equivalence class of x is the orbit Gx, since

$$\begin{aligned} [x] &= \{\, y \in X \mid x \sim y \,\} \\ &= \{\, y \in X \mid \exists\, g \in G : y = gx \,\} \\ &= \{\, gx \mid g \in G \,\} \;=\; Gx \end{aligned}$$

(ii) We will first prove that the stabilizer $G^x = \{\, g \in G \mid gx = x \,\}$ is a subgroup of G. First of all $e \in G^x$ since $ex = x$. Also if $g, h \in G^x$ then $gx = x$ and $hx = x$ such that $(gh)x = g(hx) = gx = x$, and this means $gh \in G^x$ again. Finally $g \in G^x$ implies $x = ex = (g^{-1}g)x = g^{-1}(gx) = g^{-1}x$ such that $g^{-1} \in G^x$ again. Altogether G^x is a subgroup of G. It remains to prove the well-definedness and bijectivity of the map

$$Gx \to {}^{G}\big/_{G^x} \;:\; gx \mapsto gG^x$$

Let us first check the well-definedness: If $gx = hx$ then $(h^{-1}g)x = h^{-1}(gx) = h^{-1}(hx) = (h^{-1}h)x = ex = x$ such that $h^{-1}g \in G^x$. And this again is $gG^x = hG^x$ by definition of G/P. Now the surjectivity is clear: For $g \in G$ then $gx \in Gx$ is mapped to gG^x. And for the injectivity suppose we had some $g, h \in G$ with $gG^x = hG^x$. Undoing the above computation we then have $h^{-1}g \in G^x$ such that $gx = e(gx) = (hh^{-1})gx = h((h^{-1}g)x) = hx$ again.

(iii) By definition we have $gA \subseteq A$ for any $g \in G$. But this implies $A = eA = (gg^{-1})A = g(g^{-1}A)$. As $gA \subseteq A$ is also true for g^{-1} we continue $A = g(g^{-1}A) \subseteq gA \subseteq A$ such that $gA = A$.

(iv) Given $g \in G$ and $x \in X \setminus A$ we have to show $gx \in X \setminus A$. Thus suppose we had $gx \in A$, then we would conclude $x = ex = (g^{-1}g)x = g^{-1}(gx) \in g^{-1}A \subseteq A$, in contradiction to $x \in X \setminus A$.

(v) By (ii) we have $\#Gx = \#(G/G^x)$ and (as both, G and X are finite) by the theorem of Lagrange (1.7) this implies

$$\#Gx \;=\; [G : G^x] \;=\; \frac{\#G}{\#G^x}$$

Now the second orbit formula is a simple consequence: As $\sim$ is an equivalence relation the orbits Gx form a partition of X and hence

$$\#X \;=\; \sum_{Gx \in X/G} \#Gx \;=\; \#G \cdot \sum_{Gx \in X/G} \frac{1}{\#G^x}$$

(vi) The idea of this proof is the identity of the disjoint unions of the stabilizers $G^x = \{\, g \in G \mid gx = x \,\}$ and the fixed point sets $X^g = \{\, x \in X \mid gx = x \,\}$ below. Taking to the unions we find

$$\bigcup_{g \in G} \{\, g \,\} \times X^g \;=\; \{\, (g, x) \in G \times X \mid gx = x \,\} \;=\; \bigcup_{x \in X} G^x \times \{\, x \,\}$$

And as these unions are disjoint (by construction) we hence already have proved the second part of Burnsides formula

$$\sum_{g\in G} \#X^g \;=\; \sum_{x\in X} \#G^x$$

For the first part we use the partition of X into orbits Gx again, that is $X = \bigcup Gx$ where the union runs over all orbits $Gx \in X/G$. This can be used to split the sum over all $x \in X$ into two separate sums the first over $Gx \in X/G$ the second over $y \in Gx$

$$\sum_{x\in X} \#G^x \;=\; \sum_{Gx\in X/G} \sum_{y\in Gx} \#G^x \;=\; \sum_{Gx\in X/G} \#Gx \cdot \#G^x$$

But by the orbit fomula in (iv) we have $\#Gx \cdot \#G^x = \#G$ identically, such that this sum is reduced once again, leaving only

$$\sum_{x\in X} \#G^x \;=\; \sum_{Gx\in X/G} \#G \;=\; \#G \cdot \#{}^{X}\big/_{G}$$

□

15.2 Proofs of Chapter 1

In order to be able to provide the proofs of the first introductory chapter to algebra, we have to make some preparations: Division with remainder in the integers and we promised to present a way to deal with bracketing formally. We chose to keep the latter out of the main text, as it is rather formal and little suited for a beginners in algebra. As we want to stay rigorous, we chose to present it nevertheless, so this only leaves a place in the back yard - here. We also pulled up front some elementary proofs, that should be done, as soon as possible.

Division with Remainder:
Consider any $d \in \mathbb{N}$ with $d \geq 1$ which we call the *divisor*. Then for any $x \in \mathbb{Z}$ there are uniquely determined $q, r \in \mathbb{Z}$ such that

(1) $x = qd + r$

(2) $r \in 0 \dots (d-1)$

This result will be largely generalized in section 2.7 and proved in greater generality, but as we use this fact for $\mathbb{Z}$ we have to give a proof beforehand. The numbers q and r in the statement above can even be given explicitly

$$\begin{aligned} q &= x \text{ div } d &:=& \quad \max\{\, k \in \mathbb{Z} \mid kd \leq x \,\} \\ d &= x \text{ mod } d &:=& \quad x - (x \text{ div } d) \cdot d \end{aligned}$$

Prob *Existence:* as $x \leq |x| \leq |x| \cdot d$ then set $\{\, k \in \mathbb{Z} \mid kd \leq x \,\}$ is bounded from above by $|x|$. Hence the maximum $q := \max\{\, k \in \mathbb{Z} \mid kd \leq x \,\}$ is well defined. Also take $r := x - qd \in \mathbb{Z}$. Then (1) $x = qd + r$ is clear from the definition of r and as $qd \leq x$ we also have $r \geq 0$. Now suppose $r \geq d$ then we would have $0 \leq r - d = x - qd - d = x - (q+1)d$ such that $(q+1)d \leq x$. But as q has been maximal, this is absurd, which only leaves $r < d$, such that (2) is established, as well.
Uniqueness: suppose $x = qd + r$ and $x = ud + v$ for some q, r, u and $v \in \mathbb{Z}$ with r and $v \in 0 \dots (d-1)$. Then $0 = x - x = qd + r - (ud + v) = (q-u)d + r - v$. That is d divides $(q-u)d = v - r$. But as $0 \leq v$, $r < d$ we have $|v - r| < d$ and hence $v - r$ can only be divided by d, if $v - r = 0$. That is $r = v$ and therefore $qd + r = ud + v$ implies $qd = ud$ which also yields $q = u$. □

Formal Bracketing $(\diamondsuit)$
If we multiply (or sum up) several elements $x_1, \dots, x_n \in G$ of a groupoid $(G, \circ)$ we've got $(n-1)$ possibilities, with which two elements we start - even if we keep their ordering. And we have to keep choosing until we finally got one element of G. In this light it is quite clear, what we mean by saying "any way of applying parentheses to the product of the x_i results in the same element". It just says, that the result actually doesn't depend on our choices. However - as we do math - we wish to give a formal way of putting this. To do this first define a couple mappings for $2 \leq n \in \mathbb{N}$ and $k \in 2 \dots (n-2)$

$$\begin{aligned} b_{(n,1)} &: G^n \to G^{n-1} : (x_1, \dots, x_n) \mapsto (x_1 x_2, x_3, \dots, x_n) \\ b_{(n,k)} &: G^n \to G^{n-1} : (x_1, \dots, x_n) \mapsto (x_1, \dots, x_k x_{k+1}, \dots, x_n) \\ b_{(n,n-1)} &: G^n \to G^{n-1} : (x_1, \dots, x_n) \mapsto (x_1, \dots, n_{n-2}, x_{n-1} x_n) \end{aligned}$$

Now we can determine the sequel of choosing the parentheses simply by selecting an $(n-1)$-tupel k in the following set

$$D_n \;:=\; \{\, k=(k_1,\ldots,k_{n-1}) \mid k_i \in 1\ldots(n-i) \text{ for } i \in 1\ldots(n-1)\,\}$$

For fixed $k \in D_n$ the *bracketing* (by k) now simply is the following mapping

$$B_k \;:=\; b_{(2,k_{n-1})} \circ \cdots \circ b_{(n,k_1)} \;:\; G^n \to G$$

Proof of (1.2) (associativity): $(\diamondsuit)$
We now wish to prove the fact that in a groupoid $(G,\circ)$ the product of the elements $x_1,\ldots,x_n$ is independent of the order in which we applied parentheses to it. Formally this can now be put as: for any $k \in D_n$ we get

$$B_k(x_1,\ldots,x_n) \;=\; x_1x_2\ldots x_n$$

We will prove this statement by induction on the number n of elements multiplied. In the cases $n=1$ and $n=2$ there only is one possibility how to apply parentheses and hence the statement is trivial. The case $n=3$ there are two possibilities, which are equal due to the associativity law (A) of $(G,\circ)$. Thus we assume $n>3$ and regard two ways of applying parentheses $k,l \in D_n$, writing them in terms of the last multiplication used

$$\begin{aligned} a \;:=\; B_k(x_1,\ldots,x_n) &= B_p(x_1,\ldots,x_i)B_p(x_{i+1},\ldots,x_n) \\ b \;:=\; B_l(x_1,\ldots,x_n) &= B_q(x_1,\ldots,x_j)B_q(x_{j+1},\ldots,x_n) \end{aligned}$$

where $i := k_1$, $j := l_1$ and $p := (k_2,\ldots,k_{n-1})$, $q := (l_2,\ldots,l_{n-1})$. We may assume $i \le j$ and if $i=j$ we are already done because of the induction hypothesis. Thus we have $i<j$ and by the induction hypothesis the parentheses may be rearranged to

$$\begin{aligned} a &= \Big((x_1\ldots x_i)\Big((x_{i+1}\ldots x_j)(x_{j+1}\ldots x_n)\Big)\Big) \\ b &= \Big(\Big((x_1\ldots x_i)(x_{i+1}\ldots x_j)\Big)(x_{j+1}\ldots x_n)\Big) \end{aligned}$$

Now the associativity law again implies $a=b$ and as k and l were arbitrary this implies $a = x_1x_2\ldots x_n$ for any bracketing k chosen. □

Proof of (1.5):

- Let $(G,\circ)$ be any group, then $ee=e=ee$ and hence $e=e^{-1}$ by definition of the inverse element. Likewise if $y=x^{-1}$ then $xy=e=yx$ and hence $x=y^{-1}$. Then we prove $(xy)^{-1}=y^{-1}x^{-1}$ by

$$\begin{aligned} (xy)(y^{-1}x^{-1}) &= x\Big(y(y^{-1}x^{-1})\Big) \;=\; x\Big((yy^{-1})x^{-1}\Big) \\ &= x\Big(ex^{-1}\Big) \;=\; xx^{-1} \;=\; e \\ (y^{-1}x^{-1})(xy) &= y^{-1}\Big(x^{-1}(xy)\Big) \;=\; y^{-1}\Big((x^{-1}x)y\Big) \\ &= y^{-1}\Big(ey\Big) \;=\; y^{-1}y \;=\; e \end{aligned}$$

- Next we will prove $(x^k)^{-1} = (x^{-1})^k$ by induction on $k \geq 0$. If $k = 0$ then the claim is satisfied, as $e^{-1} = e$. Now we conduct the induction step, using what we have just proved:

$$\left(x^{k+1}\right)^{-1} \;=\; \left(x^k x\right)^{-1} \;=\; x^{-1}\left(x^k\right)^{-1} \;=\; x^{-1}\left(x^{-1}\right)^k \;=\; \left(x^{-1}\right)^{k+1}$$

- Now assume that $xy = yx$ do commute. Then it is easy to see that $x^{-1}y^{-1} = y^{-1}x^{-1} = (xy)^{-1}$ do commute as well, just compute

$$y^{-1}x^{-1} \;=\; (xy)^{-1} \;=\; (yx)^{-1} \;=\; x^{-1}y^{-1}$$

 And by induction on $k \geq 0$ it also is clear, that $x^k y = yx^k$. Now we will prove $(xy)^k = x^k y^k$ by induction on k. In the case $k = 0$ everything is clear $(xy)^0 = e = ee = x^0 y^0$. Now compute

$$\begin{aligned}\left(xy\right)^{k+1} &= \left(xy\right)^k\left(xy\right) \;=\; \left(x^k y^k\right)\left(yx\right)\\ &= x^k\left(y^k(yx)\right) \;=\; x^k\left(y^{k+1}x\right)\\ &= x^k\left(xy^{k+1}\right) \;=\; x^{k+1}y^{k+1}\end{aligned}$$

 And for negative k we regard $-k$ where $k \geq 0$, then we easily compute

$$\begin{aligned}\left(xy\right)^{-k} &= \left((xy)^{-1}\right)^k \;=\; \left(x^{-1}y^{-1}\right)^k\\ &= \left(x^{-1}\right)^k\left(y^{-1}\right)^k \;=\; x^{-k}y^{-k}\end{aligned}$$

- Note: in the last step of the above we have used $(x^{-1})^k = x^{-k}$. But we still have to prove this equality: as for any $x \in G$ we find that $xx^{-1} = e = x^{-1}x$ do commute we also obtain $x^{-k} = (x^k)^{-1} = (x^{-1})^k$ for any $k \geq 0$, just compute

$$x^{-k}x^k \;=\; \left(x^{-1}\right)^k x^k \;=\; \left(x^{-1}x\right)^k \;=\; e^k \;=\; e$$

$$x^k x^{-k} \;=\; x^k\left(x^{-1}\right)^k \;=\; \left(xx^{-1}\right)^k \;=\; e^k \;=\; e$$

- This also allows us to prove $(x^k)^l = x^{kl}$ for any $k, l \in \mathbb{Z}$. We will distinguish four cases - to do this assume $k, l \geq 0$ then

$$\left(x^k\right)^l \;=\; x^k x^k \ldots x^k \;\; (l - \text{times}) \;=\; x^{kl}$$

$$\left(x^{-k}\right)^l \;=\; \left((x^{-1})^k\right)^l \;=\; \left(x^{-1}\right)^{kl} \;=\; x^{-(kl)} \;=\; x^{(-k)l}$$

$$\left(x^k\right)^{-l} \;=\; \left((x^k)^{-1}\right)^l \;=\; \left((x^{-1})^k\right)^l \;=\; x^{-(kl)} \;=\; x^{k(-l)}$$

$$\left(x^{-k}\right)^{-l} = \left(((x^{-1})^k)^{-1}\right)^l = \left(((x^k)^{-1})^{-1}\right)^l \;=\; x^{kl} \;=\; x^{(-k)(-l)}$$

- It remains to prove $x^k x^l = x^{k+l}$ for any $k, l \in \mathbb{Z}$. As above we will distinguish four cases, that is

we regard $k, l \geq 0$. In this case $x^k x^l = x^{k+l}$ is clear by definition. Further we can compute

$$x^{-k}x^{-l} \;=\; \left(x^{-1}\right)^k \left(x^{-1}\right)^l \;=\; \left(x^{-1}\right)^{k+l} \;=\; x^{-(k+l)} \;=\; x^{(-k)+(-l)}$$

For the remaining two cases we first show $x^{-1}x^l = x^{l-1}$. In case $l \geq 0$ this is immediately clear. And in case $l \leq 0$ we regard $-l$ with $l \geq 0$

$$x^{-1}x^{-l} \;=\; x^{-1}\left(x^{-1}\right)^l \;=\; \left(x^{-1}\right)^{l+1} \;=\; x^{-(l+1)} \;=\; x^{(-l)-1}$$

We are now able to prove $x^{-k}x^l = x^{(-k)+l}$ by induction on k. The case $k = 0$ is clear, for the induction step we compute

$$x^{-(k+1)}x^l = (x^{-1})^k x^{-1}x^l = (x^{-1})^k x^{-1}x^l = x^{-k}x^{l-1} = x^{-(k+1)+l}$$

The fourth case finally is $x^k x^{-l} = x^{k+(-l)}$, but as x^k and x^{-l} commute (use inductions on k and l) this readily follows the above.

□

Proof of (1.7):
The first statement that needs to be verified is that a subgroup $P \leq_g G$ truly invokes an equivalence relation $x \sim y \iff y^{-1}x \in P$. This relation clearly is reflexive: $x \sim x$ due to $x^{-1}x = e \in P$. And it also is transitive because if $x \sim y$ and $y \sim z$ then $y^{-1}x \in P$ and $z^{-1}y \in P$. Thereby $z^{-1}x = z^{-1}(yy^{-1})x = (z^{-1}y)(y^{-1}x) \in P$ too, which again means $x \sim z$. Finally it is symmetric as well: if $x \sim y$ then $y^{-1}x \in P$ and hence $x^{-1}y = (y^{-1}x) \in P$ too, which is $y \sim x$. Next we wish to prove that truly $[x] = xP$

$$\begin{aligned} [x] \;&=\; \{\, y \in G \mid y \sim x \,\} \;=\; \left\{\, y \in G \mid x^{-1}y = p \in P \,\right\} \\ &=\; \{\, y \in G \mid \exists\, p \in P : y = xp \,\} \;=\; \{\, xp \mid p \in P \,\} \;=\; xP \end{aligned}$$

So it only remains to prove the theorem of Lagrange. To do this we fix a system $\mathbb{P}$ of representatives of G/P. That is we fix a subset $\mathbb{P} \subseteq G$ such that $\mathbb{P} \longleftrightarrow G/P : q \mapsto qP$ (which is possible due to the axiom of choice). Then we obtain a bijection by letting

$$G \longleftrightarrow \left(G \Big/ P\right) \times P \;:\; x \mapsto \left(xP,\; q^{-1}x \text{ where } xP = qP\right)$$

This map is well defined: as $xP \in G/P$ there is a uniquely determined $q \in \mathbb{P}$ such that $qP = xP$. And for this we get $q \sim x$ which means $q^{-1}x \in P$. And it is injective: if $xP = yP = qP$ then $q^{-1}x = q^{-1}y$ yields $x = y$ (by multiplication with q). Finally it also is surjective: given (qP, p) we let $x := qp \in qP$ and thereby obtain $q \sim x$ and hence $(xP, q^{-1}x) = (qP, p)$. □

Proof of (1.8):
We first have to prove, that $\langle X \rangle_o$ is a well-defined submonoid of G. As $X \subseteq G$ and G is a submonoid, the intersection runs over a non-empty set and hence is well-defined. Also, as $e \in X_e$, we clearly have $e \in \langle X \rangle_o$. And if x and $y \in \langle X \rangle_o$ then for any $P \leq_o G$ with $X \subseteq P$ we have $x, y \in P$. But as P is a submonoid this implies $xy \in P$ again and as this is true for any P we also get $xy \in \langle X \rangle_o$ again.
Likewise if G is a group, then (by the same arguments as above) $\langle X \rangle_g$ is a submonoid of G. It remains to

prove that it even is a subgroup: But as P is a subgroup this implies $x^{-1} \in P$ again and as this is true for any P we also get $x^{-1} \in \langle X \rangle_o$ again.
Next we will prove the explict representation of $\langle X \rangle_o$, to to this let us denote the set of finite products of elements of X_e by

$$Q \;:=\; \{\, x_1 x_2 \dots x_n \mid n \in \mathbb{N},\, x_1, \dots, x_n \in X_e \,\}$$

As $e \in X_e$ it is clear that $e \in Q$. And if $x = x_1 \dots x_m$ and $y = y_1 \dots y_n \in Q$ then by construction we also have $xy \in Q$. That is: Q is a submonoid of G and as $X \subseteq Q$ is clear we have $\langle X \rangle_o \subseteq Q$. Conversely, as $\langle X \rangle_o$ is a monoid with $X \subseteq \langle X \rangle_o$ we have e and $x \in \langle X \rangle_o$ for any $x \in X$. That is $X_e \subseteq \langle X \rangle_o$. Therefore, if $x_1, \dots, x_n \in X_e$ then $x_1 \dots x_n \in \langle X \rangle_o$ again and this also is $Q \subseteq \langle X \rangle_o$. Together we have $Q = \langle X \rangle_o$.
We finally have to prove the explicit representation of $\langle X \rangle_g$, to do this let us abbreviate the set of finite products of elements of $X_\pm$ by

$$Q \;:=\; \{\, x_1 x_2 \dots x_n \mid n \in \mathbb{N},\, x_1, \dots, x_n \in X_\pm \,\}$$

If $x \in X$ we also have $x^{-1} \in X_\pm$ and as $(x^{-1})^{-1} = x$ we find that $x^{-1} \in X_\pm$ for any $x \in X_\pm$. That is $X_\pm$ is closed under the inversion of elements. Also $e \in X_\pm$ is trivial. And if $x = x_1 \dots x_m$ and $y = y_1 \dots y_n \in Q$ then by construction we also have $xy \in Q$. But also $x^{-1} = x_m^{-1} \dots x_1^{-1} \in Q$, as with $x_i \in X_\pm$ we also have $x_i^{-1} \in X_\pm$. Hence Q is a subgroup of G and as $X \subseteq Q$ is clear we have $\langle X \rangle_g \subseteq Q$. Conversely, as $\langle X \rangle_g$ is a group with $X \subseteq \langle X \rangle_g$ we have e, x and $x^{-1} \in \langle X \rangle_g$ for any $x \in X$. That is $X_\pm \subseteq \langle X \rangle_g$. Therefore, if $x_1, \dots, x_n \in X_\pm$ then $x_1 \dots x_n \in \langle X \rangle_g$ again and this also is $Q \subseteq \langle X \rangle_g$. Together we have $Q = \langle X \rangle_g$. □

Proof of (1.9):
It is clear that $Q := \{\, x^k \mid k \in \mathbb{Z} \,\}$ is a subgroup of G, as for any $i, j \in \mathbb{Z}$ we have $x^i x^j = x^{i+j} \in Q$ and $(x^i)^{-1} = x^{-i} \in Q$. Also, as $x \in Q$ we get $\langle x \rangle_g \subseteq Q$. But as $x \in \langle x \rangle_g$ and $\langle x \rangle_g$ is a group we clearly have $x^k \in \langle x \rangle_g$ for any $k \in \mathbb{Z}$ and hence $Q \subseteq \langle x \rangle_g$ as well. Altogether $\langle x \rangle_g = Q$.
Now suppose $n := \#G \in \mathbb{N}$ is finite, then $Q \subseteq G$ is finite, too, say $k := \#Q$. If now $i, j \in \mathbb{N}$ with $i < j$ then (by multiplication with x^{-i} from the left) we clearly have

$$x^i \;=\; x^j \quad\Longleftrightarrow\quad x^{j-i} \;=\; e$$

Thus if we had $x^p \neq e$ for any $p \in \mathbb{N}$ then $x^i \neq x^j$ for any $i < j$ and hence $\langle x \rangle_g$ had infinitely many elements. As this is untrue, there has to be some $p \in \mathbb{N}$ with $1 \leq p$ such that $x^p = e$. Let $m \in \mathbb{N}$ be the minimal such number

$$m \;:=\; \min\{\, 1 \leq p \in \mathbb{N} \mid x^p = e \,\}$$

As $x^m = e$ is the first occurance of e we have $x^i \neq e$ for any $1 \leq i < m$. And this implies $x^i \neq x^j$ for any $i, j \in \mathbb{N}$, with $i \neq j$ and $i, j < m$. Hence we have found m distinct elements in $\langle x \rangle_g$, namely

$$\left\{\, x^i \mid i \in 0 \dots (m-1) \,\right\} \quad\subseteq\quad \langle x \rangle_g$$

Conversely consider any $x^q \in \langle x \rangle_g$ and write $q = pm + i$ by division of q by m with remainder $i \in 0 \dots (m-1)$. Then $x^q = x^{pm+i} = (x^m)^p x^i = e^p x^i = x^i$. That is $\langle x \rangle_g$ only consists of elements of the form x^i for some $0 \leq i < m$ and hence the above sets even are equal. In particular we have $m = k$. And

as $\langle x \rangle_g$ is a subgroup of G the theorem of Lagrange (1.7) truly implies $k \mid n$.
Let us finally prove $x^n = e$: To see this let $k := \mathrm{ord}(x)$, in particular $x^k = e$. As we have just seen $k \mid n$ there is some $q \in \mathbb{Z}$ such that $n = qk$. And thereby $x^n = x^{qk} = (x^k)^q = e^q = e$. □

Proof of (1.10):
If σ and $\tau : X \to X$ then the composition $\sigma\tau : x \mapsto \sigma(\tau(x))$ is another map of the form $\sigma\tau : X \to X$. And if both σ and τ are bijective, so is $\sigma\tau$ with inverse $(\sigma\tau)^{-1} = \tau^{-1}\sigma^{-1}$. Hence S_X is closed under the compositon $\circ$. And the associativity of the composition is well-known. Also $\mathbb{1}_X : x \mapsto x$ is bijective and hence $\mathbb{1}_X \in S_X$. Hence $(S_X, \circ)$ is a monoid. And as σ^{-1} is the inverse element of σ and bijective again we have $\sigma^{-1} \in S_X$ again, such that S_X is a group. □

Proof of (1.12):

(i) By induction on the number of elements $n := \#X$: In case $n = 1$ we have $X = \{ x \}$ for some single element $x \in X$. Hence the one any only map on X is given to be $\sigma(x) = x$. In particular $\#S_X = 1 = 1! = (\#X)!$. Now for the induction step we consider a set with $n+1$ elements $X = \{ x_1, \ldots, x_n, x_{n+1} \}$. Then we can decompose S_X into the following disjoint union

$$S_X \;=\; \bigcup_{i=1}^{n+1} F(i) \quad \text{where} \quad F(i) \;:=\; \{ \sigma \in S_X \mid \sigma(x_{n+1}) = x_i \}$$

Clearly, if $\sigma(x_{n+1}) = x_i$, then σ induces a bijection between the sets $X(i) := X \setminus \{ x_i \}$ and $X(n+1)$. As $X(i)$ always contains n elements we can choose a bijection $\alpha_i : X(i) \longleftrightarrow X(n+1)$. And this now gives rise to a bijection between

$$F(i) \longleftrightarrow S_{X(n+1)} \;:\; \sigma \mapsto \alpha_i \sigma\big|_{X(n+1)}$$

In particular for any $i \in 1 \ldots n+1$ the set $F(i)$ contains as many elements, as $S_{X(n+1)}$. And by induction hypothesis, as $\#X(n+1) = n$ this is $n!$. So altogether

$$\#S_X \;=\; \sum_{i=1}^{n+1} \#F(i) \;=\; (n+1)\, n! \;=\; (n+1)!$$

(ii) Let us define an equivalence relation on S_{n+1} by letting $\varrho \sim \sigma$ if and only if $\varrho(n+1) = \sigma(n+1)$. Then it is clear that the equivalence classes of this relation are precisely the sets

$$E_k \;:=\; \{ \sigma \in S_{n+1} \mid \sigma(n+1) = k \}$$

where k runs from 1 to $n+1$. E.g. the transposition τ_k belongs to E_k (that is $[\tau_k] = E_k$) since $\tau_k(n+1) = k$. In particular the sets E_k form a pairwise disjoint [i.e. for any $i \neq j \in 1 \ldots n+1$ we have $E_i \cap E_j = \emptyset$] union of S_{n+1}. So it only remains to prove the equality of the sets

$$E_k \;=\; \tau_k S'_n \;=\; \{ \tau_k \pi \mid \pi \in S'_n \}$$

For the inclusion " $\supseteq$ " we are given some $\pi \in S'_n$ and have to regard $\sigma := \tau_k \pi$. But clearly $\sigma(n+1) = \tau_k \pi(n+1) = \tau_k(n+1) = k$ such that $\sigma \in E_k$. Conversely, if $\sigma(n+1) = k$ then we define $\pi := \tau_k \sigma$ and find $\pi(n+1) = \tau_k \sigma(n+1) = \tau_k(k) = n+1$. Thereby $\pi \in S'_n$ and

$\tau_k\pi = \tau_k^2\sigma = \sigma$ such that we find $\sigma \in \tau_k S_n'$ as well.

(iii) First of all we see that for any g, h and $x \in G$ the associativity of G gives birth to the following equality: $L_{gh}(x) = (gh)x = g(hx) = L_g(hx) = L_g(L_h(x)) = L_g L_h(x)$. And as $x \in G$ has been arbitrary this is $L_{gh} = L_g L_h$. Also it is clear that $L_e(x) = ex = x = \mathbb{1}_G(x)$ such that $L_e = \mathbb{1}_G$. In particular $L_{g^{-1}}$ is the inverse map of L_g since

$$L_{g^{-1}}L_g \;=\; L_{g^{-1}g} \;= L_e \;=\; \mathbb{1}_G$$

$$L_g L_{g^{-1}} \;=\; L_{gg^{-1}} \;= L_e \;=\; \mathbb{1}_G$$

In particular $L_g : G \to G$ not only is a map, but even a bijective one. Hence $L_g \in S_G$ and this makes L well-defined. It remains to show the injectivity of L but this is easy: if $L_g = L_h$ then $g = ge = L_g(e) = L_h(e) = he = h$.

□

Proof of (1.14):

(i) As $n = \#X$ is finite S_X is a finite group with $n!$ elements. And as $S := \{\, \sigma^k \mid k \in \mathbb{Z} \,\}$ is a subgroup of the finite group S_X [this has been shown in (1.12.(i))], we know from (1.9), that there is some $k \in \mathbb{N}$ with $\sigma^k = \mathbb{1}$, say $k = \mathrm{ord}(\sigma)$. In particular $\sigma^k(x) = x$ such that the cycle $\mathrm{cyc}(\sigma, x)$ if finite, with $\ell(\sigma, x) \leq k = \mathrm{ord}(\sigma)$.

(ii) If $x \in \mathrm{fix}(\sigma)$, then $\sigma(x) = x$, by definition. In particular we have $\sigma(x) \in \mathrm{fix}(\sigma)$ for any $x \in \mathrm{fix}(\sigma)$ and thereby $\sigma(\mathrm{fix}(\sigma)) \subseteq \mathrm{fix}(\sigma)$. Conversely regard some $x \in \mathrm{fix}(\sigma)$ and let $u := \sigma^{-1}(x) \in X$. Then $\sigma(u) = x \in \mathrm{fix}(\sigma)$. That is $\sigma(\sigma(u)) = \sigma(u)$. As σ is injective, we conclude $\sigma(u) = u$ and thereby $u \in \mathrm{fix}(\sigma)$ again. That is $x = \sigma(u) \in \sigma(\mathrm{fix}(\sigma))$ and this is the converse inclusion $\mathrm{fix}(\sigma) \subseteq \sigma(\mathrm{fix}(\sigma))$. Altogether

$$\sigma\big(\mathrm{fix}(\sigma)\big) \;\subseteq\; \mathrm{fix}(\sigma)$$

Now for the domain of σ: Suppose we had $y := \sigma(x) \in \mathrm{fix}(\sigma)$, then we had $\sigma(y) = y = \sigma(x)$. But as σ is injective this would imply $x = y \in \mathrm{fix}(\sigma)$ which is absurd, since we started with $x \in \mathrm{dom}(\sigma)$. This is the inclusion $\sigma(\mathrm{dom}(\sigma)) \subseteq \mathrm{dom}(\sigma)$. Conversely regard some $x \in \mathrm{dom}(\sigma)$ and let $u := \sigma^{-1}(x) \in X$. Suppose we had $u \in \mathrm{fix}(\sigma)$, then $x = \sigma(u) = u$ such that $\sigma(x) = \sigma(u) = x$ in contradiction to $x \in \mathrm{dom}(\sigma)$. Thus we have $u \in \mathrm{dom}(\sigma)$ again and thereby $x = \sigma(x) \in \sigma(\mathrm{dom}(\sigma))$, which is the converse inclusion. Altogether we also found

$$\sigma\big(\mathrm{dom}(\sigma)\big) \;\subseteq\; \mathrm{dom}(\sigma)$$

If now $x \in \mathrm{dom}(\sigma)$ then we will use induction on k to prove that any $\sigma^k(x)$ lies within $\mathrm{dom}(\sigma)$: The case $k = 0$ is true by assumption $\sigma^0(x) = x \in \mathrm{dom}(\sigma)$. Now $\sigma^{k+1}(i) = \sigma(\sigma^k(x))$ and by induction hypothesis we know $\sigma^k(x) \in \mathrm{dom}(\sigma)$. Hence $\sigma^{k+1}(x) \in \sigma(\mathrm{dom}(\sigma)) = \mathrm{dom}(\sigma)$ again.

(iii) If $\varrho = \sigma$ then $\mathrm{dom}(\varrho) = \mathrm{dom}(\sigma)$ and $\varrho(x) = \sigma(x)$ for any $x \in D$ are trivial, as we even have $\varrho(x) = \sigma(x)$ for any $x \in X$. Conversely let $D = \mathrm{dom}(\varrho) = \mathrm{dom}(\sigma)$. If $x \in D$ then $\varrho(x) = \sigma(x)$ by assumption. But if $x \notin D$ then we have $x \in \mathrm{fix}(\varrho)$ and $x \in \mathrm{fix}(\sigma)$ such that $\varrho(x) = x = \sigma(x)$. Hence we have $\varrho(x) = \sigma(x)$ for any $x \in X$ and this is $\varrho = \sigma$, as claimed.

(iv) If $x \in \mathrm{dom}(\varrho)$ then by assumption we have $x \notin \mathrm{dom}(\sigma)$ such that $x \in \mathrm{fix}(\sigma)$. In particular we get

$$\varrho\sigma(x) \;=\; \varrho(x)$$

And as we know $\varrho(x) \in \mathrm{dom}(\varrho)$ again, because of (ii), we likewise have $\varrho(x) \in \mathrm{fix}(\sigma)$ such that we also find

$$\sigma\varrho(x) \;=\; \varrho(x)$$

That is $\varrho\sigma(x) = \varrho(x) = \sigma\varrho(x)$ for any $x \in \mathrm{dom}(\varrho)$. In complete analogy (by interchanging the roles of ϱ and σ) we find (for any $x \in \mathrm{dom}(\sigma)$)

$$\sigma\varrho(x) \;=\; \sigma(x) \;=\; \varrho\sigma(x)$$

And if finally $x \in X \setminus (\mathrm{dom}(\varrho) \cup \mathrm{dom}(\sigma)) = \mathrm{fix}(\varrho) \cap \mathrm{fix}(\sigma)$ then it is clear that $\varrho\sigma(x) = \varrho(x) = x$ and also $\sigma\varrho(x) = \sigma(x) = x$. In any case we have seen (for any $x \in X$) that $\varrho\sigma(x) = \sigma\varrho(x)$, which is the commutativity $\varrho\sigma = \sigma\varrho$.

□

Proof of (1.16):

- As long as the order of the i_k is maintained, we still have $i_k \mapsto i_{k+1}$ (and $i_\ell \mapsto i_1$) no matter with wich element i_k we begin. Hence

$$(i_1\, i_2\, \ldots\, i_\ell) \;=\; (i_2\, i_3\, \ldots\, i_\ell\, i_1) \;=\; \ldots \;=\; (i_\ell\, i_1\, i_2\, \ldots\, i_{\ell-1})$$

- Let us denote $\zeta := (i_1\; i_\ell)(i_1\; i_{\ell-1}) \ldots (i_1\; i_2)$, then given any $a = i_q$ let us regard ζ from the right: i_q is unaffected by any $(i_1\; i_p)$ with $p < q$. Hence i_q it first hits $(i_1\; i_q)$ which maps $i_q \to i_1$. Now i_1 immediatley strikes $(i_1\; i_{q+1})$ again mapping $i_1 \mapsto i_{q+1}$. And i_{q+1} passes through unhampered, as it only meets $(i_1 i_r)$ whith $r > q+1$ from now on. Altogether we have $\zeta : i_q \mapsto i_1 \mapsto i_{q+1}$. A special case is $a = i_\ell$ as this only strikes $(i_1 i_\ell)$ at the very end, such that $\zeta : i_\ell \mapsto i_1$. Therefore $\zeta = (i_1\; i_2\; \ldots\; i_\ell)$.

- By induction on $d := j - i \in \mathbb{N}$. The case $d = 1$ is trivial, as $(i\; j) = (i\; i+1)$ in this case. For $d \geq 2$ we have to regard $(i\; j) = (i\; i+d)$. To do this we first prove that $(i\; i+d) = (i\, i+1)(i+1\; i+d)(i\, i+1)$ by explicitly computing (from right to left):

$$\begin{array}{ccccccc}
 & (i\, i+1) & & (i+1\, i+d) & & (i\, i+1) & \\
i+d & \hookleftarrow & i+d & \hookleftarrow & i+1 & \hookleftarrow & i \\
i+1 & \hookleftarrow & i & \hookleftarrow & i & \hookleftarrow & i+1 \\
i & \hookleftarrow & i+1 & \hookleftarrow & i+d & \hookleftarrow & i+d
\end{array}$$

 As the domain of $\zeta = (i\; i+1)(i+1\; i+d)(i\; i+1)$ is $\mathrm{dom}(\zeta) = \{\, i, i+1, i+d \,\}$ it is clear, that $\zeta(a) = a$ for any $a \notin \{\, i, i+1, i+d \,\}$. And as $\zeta(i) = i+d$, $\zeta(i+1) = i+1$ and $\zeta(i+d) = i$ we have truly shown that $\zeta = (i\; i+d)$. But by induction hypothesis $(i+1\; i+d)$ is of distance $d-1$ and can hence be written as

$$(i+1\;\; i+d) \;=\; (i+1\;\; i+2) \ldots (i+d-1\;\; i+d) \ldots (i+1\;\; i+d)$$

Inserting this into $(i\ i+d) = (i\ i+1)(i+1\ i+d)(i\ i+1)$ we have also proved the case $d \geq 2$ and hence for any transposition, as d may be arbitrarily large.

- Let us denote the cycle $\xi := (\sigma(i_1)\ \sigma(i_2)\ \ldots\ \sigma(i_\ell))$. Then is is clear that $\mathrm{dom}(\xi) = \{\sigma(i_1), \sigma(i_2), \ldots, \sigma(i_\ell)\}$ and for any $k \in 1 \ldots \ell - 1$ we have $\xi(\sigma(i_k)) = \sigma(i_{k+1})$, also $\xi(\sigma(i_\ell)) = \sigma(i_1)$. But on the other hand it is easy to compute $\sigma\zeta\sigma^{-1}(\sigma(i_k)) = \sigma\zeta(i_k) = \sigma(i_{k+1})$ and likewise $\sigma\zeta\sigma^{-1}(\sigma(i_\ell)) = \sigma\zeta(i_\ell) = \sigma(i_1)$. Hence we have seen $\sigma\zeta\sigma^{-1}(a) = \xi(a)$ for any $a = \sigma(i_k)$ (where $k \in 1 \ldots \ell$). If now $a \in 1 \ldots n$ is none of the $\sigma(i_k)$ (that is $a \notin \mathrm{dom}(\xi)$) then $\sigma^{-1}(a) \notin \{i_1, i_2, \ldots, i_\ell\} = \mathrm{dom}(\zeta)$. Therefore we have $\sigma\zeta\sigma^{-1}(a) = \sigma(\sigma^{-1}(a)) = a = \xi(a)$ again. That is $\sigma\zeta\sigma^{-1}$ and ξ share the same domain and agree on it, such that by (1.14.(iii)) they are equal.

□

Proof of (1.17):

- (a) $\Longrightarrow$ (b): by assumption we have $\sigma = (i_1\ i_2\ \ldots\ i_\ell)$ for some pairwise distinct $i_k \in 1 \ldots n$. Therefore it is clear that

$$\mathrm{dom}(\sigma) \ = \ \{i_1, i_2, \ldots, i_\ell\}$$

 Let us abbreviate $i := i_1$, then by induction on k it is clear that $i_k = \sigma^{k-1}(i)$, because $\sigma^k(i) = \sigma(\sigma^{k-1}(i)) = \sigma(i_k) = i_{k+1}$. If we are now given any $a, b \in \mathrm{dom}(\sigma)$, then there are r and $s \in 1 \ldots \ell$ such that $a = i_r = \sigma^{r-1}(i)$ and $b = i_s = \sigma^{s-1}(i)$. If $s \geq r$ then we can readily take $k := s - r \in \mathbb{N}$ to see

$$\sigma^k(a) \ = \ \sigma^{s-r}\sigma^{r-1}(i) \ = \ \sigma^{s-1}(i) \ = \ b$$

 And if $s < r$ then we take $k := \ell + s - r \in \mathbb{N}$ (which is positive, since $r \leq \ell$). Note that $\sigma^\ell(i) = \sigma\sigma^{\ell-1}(i) = \sigma(i_\ell) = i_1$ such that we can likewise compute

$$\sigma^k(a) \ = \ \sigma^{\ell+s-r}\sigma^{r-1}(i) \ = \ \sigma^{s-1}\sigma^\ell(i) \ = \ = \ \sigma^{s-1}(i) \ = \ b$$

 Thus in any case we have seen that $b = \sigma^k(i)(a)$ which had to be shown.

- (b) $\Longrightarrow$ (c): choose any $i \in \mathrm{dom}(\sigma)$ then by assumption we have $b = \sigma^k(i)$ for any $b \in \mathrm{dom}(\sigma)$ for some sufficient $k \in \mathbb{N}$. That is

$$\mathrm{dom}(\sigma) \ \subseteq \ \left\{ \sigma^k(i) \mid k \in \mathbb{N} \right\}$$

 But the converse inclusion is a generat truth, for any permutation, as we have shown in (1.18.(ii)). And hence the above inclusion even is an equality of sets. Now (c) $\Longrightarrow$ (d) is trivial - note that $\mathrm{dom}(\sigma) \neq \emptyset$ is nonempty, as we assumed $\sigma \neq \mathbb{1}$.

- (d) $\Longrightarrow$ (e): all we have to do is prove, that the higher powers k of $\sigma^k(i)$ are already contained in $\{\sigma^r(i) \mid r \in 0 \ldots \ell - 1\}$. So consider any $k \geq \ell$, then we use division with remainder to write k as $k = m\ell + r$ for some $m \in \mathbb{N}$ and $r \in 0 \ldots \ell - 1$. As $\ell = \mathrm{ord}(\sigma)$ we have $\sigma^\ell = \mathbb{1}$ such that we are enabled to compute

$$\sigma^k(i) \ = \ \sigma^{m\ell+r}(i) \ = \ \left(\sigma^\ell\right)^m \sigma^r(i) \ = \ \mathbb{1}^m\sigma^r(i) \ = \ \sigma^r(i)$$

Hence any $\sigma^k(i)$ is contained in $\{\sigma^r(i) \mid r \in 0 \dots \ell - 1\}$ such that we get $\mathrm{dom}(\sigma) = \{\sigma^r(i) \mid r \in 0 \dots \ell - 1\}$ due to the assumption (d).

- (e) $\implies$ (a): let us take $i_k := \sigma^{k-1}(i)$ for any $k \in 1 \dots \ell$. We first prove that there elements are truly pairwise distinct: Suppose $i_r = i_s$ for some $r \neq s$, without loss of generality we can take $r < s$. Then $\sigma^{r-1}(i) = \sigma^{s-1}(i)$ implies $\sigma^{s-r}(i) = i$ (by multiplication with σ^{1-r} from the left). That is there would have to be some $h = s - r \in \mathbb{N}$ with $\sigma^h(i) = i$. Thereby $h = s - r < s \leq \ell$ such that $h \in 1 \dots \ell - 1$. As $\ell = \mathrm{ord}(\sigma)$ is the minimal number with $\sigma^\ell = \mathbb{1}$ this implies $\sigma^h \neq \mathbb{1}$, that is there has to be some $a \in 1 \dots n$ with $\sigma^h(a) \neq a$. In particular $a \in \mathrm{dom}(\sigma)$ as else we would also have $\sigma^h(a) = a$. By assumption there hence is some $k \in 0 \dots \ell - 1$ such that $a = \sigma^k(i)$. Now compute
$$\sigma^h(a) \;=\; \sigma^h\sigma^k(i) \;=\; \sigma^k\sigma^h(i) \;=\; \sigma^k(i) \;=\; a$$
in contradiction to $\sigma^h(a) \neq a$. Hence the assumption $i_r = i_s$ must have been false, that is the i_k are pairwise distict. Hence we are entitled to define $\zeta := (i_1\ i_2\ \dots\ i_\ell)$. Then for any $k \in 1 \dots \ell - 1$ it is clear that $\zeta(i_k) = i_{k+1} = \sigma^k(i) = \sigma(\sigma^{k-1}(i)) = \sigma(i_k)$. However we also find $\zeta(i_\ell) = i_1 = i = \sigma^\ell(i) = \sigma(\sigma^{\ell-1}(i)) = \sigma(i_\ell)$. That is we have shown that $\zeta(a) = \sigma(a)$ for any $a \in \mathrm{dom}(\zeta)$. But as
$$\mathrm{dom}(\zeta) \;=\; \{\, i_1, i_2, \dots, i_\ell \,\} \;=\; \Big\{\, \sigma^k(i) \mid k \in 0 \dots \ell - 1 \,\Big\} \;=\; \mathrm{dom}(\sigma)$$
is true by assumption, this implies $\zeta = \sigma$. That is we have shown that σ truly is the cycle generated by the i_k.
- The fact that $\ell = \mathrm{ord}(\sigma)$ can be easily seen directly. But the implication (a) $\implies$ (e) already yields $\mathrm{ord}(\sigma) = \ell$, as the length ℓ of the cycle appears in (e) as the order of σ, since $\sigma^{k-1}(i) = i_k$.

□

Proof of (1.18):

(i) Let us abbreviate $X := 1 \dots n$ and $S := \big\{\, \sigma^k \mid k \in \mathbb{Z} \,\big\}$. Then this proof could be abbreviated by noting that $S \times X \to X : (\sigma, i) \mapsto \sigma(i)$ is a group action with the orbits $Si = \mathrm{cyc}(\sigma, i)$. Anyhow we want to give a direct proof that does not require group actions:

Clearly $\sim$ is an equivalence relation, $i \sim i$ is true, due to $i = \sigma^0(i)$ and if $i \sim j$ with $j = \sigma^p(i)$ and $j \sim k$ with $k = \sigma^q(j)$ then clearly $k = \sigma^q(\sigma^p(i)) = \sigma^{p+q}(i)$ such that $i \sim k$ again. Also let $z := \mathrm{ord}(\sigma) \in \mathbb{N}$ (also see (i)), then $\sigma^z = \mathbb{1}$ such that $(\sigma^k)^{-1} = \sigma^{-k} = \sigma^z\sigma^{-k} = \sigma^{z-k}$. Hence if $i \sim j$ with $j = \sigma^k(i)$ then $i = \sigma^{z-k}(j)$ such that $j \sim i$ again. And the equivalence class is obviously given to be
$$[i] \;=\; \{\, j \in X \mid j \sim i \,\} \;=\; \Big\{\, \sigma^k(i) \mid k \in \mathbb{N} \,\Big\} \;=\; \mathrm{cyc}(\sigma, i)$$
If now $j \in \mathrm{cyc}(\sigma, i)$, then j is of the form $j = \sigma^k(i)$ for some $k \in \mathbb{N}$. In particular $\sigma(j) = \sigma^{k+1}(i) \in \mathrm{cyc}(\sigma, i)$ again. And hence we get a well-defined map
$$\zeta_i \;:\; \mathrm{cyc}(\sigma, i) \;\hookrightarrow\; \mathrm{cyc}(\sigma, i) \;:\; a \mapsto \sigma(a)$$
Once more, as σ is injective and $\mathrm{cyc}(\sigma, i)$ is a finite set we even get $\sigma(\mathrm{cyc}(\sigma, i)) = \mathrm{cyc}(\sigma, i)$ such that the above ζ_i bocomes bijective. We now expand ζ_i to $1 \dots n$ trivially by letting $\zeta_i(a) := a$ for

any $a \notin \mathrm{cyc}(\sigma, i)$. Then it is clear, that

$$\mathrm{dom}(\zeta_i) \;=\; \mathrm{cyc}(\sigma, i)$$

And as ζ_i acts on $\mathrm{cyc}(\sigma,i) = \left\{ i, \sigma(i), \ldots, \sigma^{k(i)}(i) \right\}$ just like σ does, it also is clear, that $\zeta_i = (i\ \sigma(i)\ \ldots\ \sigma^{k(i)}(i))$. Now, as $\sim$ restricts to an equivanlence relation on $\mathrm{dom}(\sigma)$ [for $a \in \mathrm{fix}(\sigma)$ the equivalence class is just $[a] = \{ a \}$] we may pick up a system of representatives $i(1), \ldots, i(r)$. As the cycles are disjoint $\mathrm{cyc}(\sigma, i(p)) \cap \mathrm{cyc}(\sigma, i(q)) = \emptyset$ for $p \neq q \in 1 \ldots r$ we find from (1.14.(iv)) that the respective cycles commute

$$p \neq q \;\in\; 1 \ldots r \quad \Longrightarrow \quad \zeta_{i(p)} \zeta_{i(q)} \;=\; \zeta_{i(q)} \zeta_{i(p)}$$

Also if $a \in \mathrm{dom}(\sigma)$ then there is precisely one $p \in 1 \ldots r$ such that $a \in \mathrm{cyc}(\sigma, i(p)) = \mathrm{dom}(\zeta_{i(p)})$. In particular we have $a \in \mathrm{fix}(\zeta_{i(q)})$ for any $q \neq p$. And hence we get

$$\left(\prod_{j=1}^{r} \zeta_{i(j)} \right)(a) \;=\; \zeta_{i(p)} \prod_{q \neq p} \zeta_{i(q)}(a) \;=\; \zeta_{i(p)}(a) \;=\; \sigma(a)$$

Thereby we only used the fact, that we can bring $\zeta_{i(p)}$ in front by successively interchanging two cycles (which is obvious by induction on r). And if $a \in \mathrm{fix}(\sigma)$ then by consruction we also have $a \in \mathrm{fix}(\zeta_{i(p)})$ for any $p \in 1 \ldots r$ such that $(\zeta_{i(1)} \ldots \zeta_{i(r)})(a) = a = \sigma(a)$. In any case we have found $\sigma(a) = (\zeta_{i(1)} \ldots \zeta_{i(r)})(a)$ such that the equality $\sigma = \zeta_{i(1)} \ldots \zeta_{i(r)}$ is finally established, as well.

(ii) Let us abbreviate $\zeta := \zeta_1 \ldots \zeta_k$ and $\xi := \xi_1 \ldots \xi_t$. We will prove this statement by induction on $m := \min\{ k, t \}$. For $m = 1$ we already have $\zeta_1 = \xi_1$ such that there is nothing to prove. For $m \geq 2$ consider any $a \in \mathrm{dom}(\zeta_1)$. By assumption this implies $a \notin \mathrm{dom}(\zeta_i)$ for any $i \neq 1$. Hence we get

$$\zeta(a) \;:=\; \zeta_1 \ldots \zeta_k(a) \;=\; \zeta_1(a)$$

In particular $a \in \mathrm{dom}(\zeta) = \mathrm{dom}(\xi)$. Likewise there is a uniquely determined $r \in 1 \ldots t$ such that $a \in \mathrm{dom}(\xi_r)$ as for any $s \neq r$ we get $a \notin \mathrm{dom}(\xi_s)$. Hence - by (ii) - we have $\xi_r(a) \in \mathrm{dom}(\xi_r)$ again such that $\xi_r(a) \notin \mathrm{dom}(\xi_s)$ for any $s \neq r$, as well. This implies

$$\xi(a) \;:=\; \xi_1 \ldots \xi_t(a) \;=\; \xi_r(a)$$

Altogether $\zeta_1(a) = \zeta(a) = \xi(a) = \xi_r(a)$. We will now prove $\mathrm{dom}(\zeta_1) = \mathrm{dom}(\xi_r)$: given any $b \in \mathrm{dom}(\zeta_1)$ there is some $p \in \mathbb{N}$ such that $b = \zeta_1^p(a)$ by virtue of (1.17.(b)), as ζ_1 is a cycle. Therefore $b = \zeta_1^p(a) = \xi_r^p(a) \in \mathrm{dom}(\xi_r)$ by (ii) again. Altogether this is

$$\mathrm{dom}(\zeta_1) \quad \subseteq \quad \mathrm{dom}(\xi_r)$$

Reversing the roles of ζ_1 and ξ_r we find the converse inclusion, such that the domains are equal. In particular, given any $a \in \mathrm{dom}(\zeta_1)$ we can repeat the above calculation, to find

$$\forall\, a \in \mathrm{dom}(\zeta_1) = \mathrm{dom}(\xi_r) \;:\; \zeta_1(a) \;=\; \xi_r(a)$$

Clearly this implies $\zeta_1 = \xi_r$. Recall that the domains of the ξ_s were assumed to be pairwise disjoint, such that by (1.14.(iv)) the ξ_s are mutually commutative. Then we can compute

$$\zeta_2 \dots \zeta_k \;=\; \zeta_1^{-1}\zeta \;=\; \xi_r^{-1}\xi \;=\; \prod_{s\neq r} \xi_s$$

Hence by induction hypotheseis we find $k-1 = t-1$ and some permutation α such that $\zeta_i = \xi_{\alpha(i)}$ for any $i \in 2 \dots k$. Clearly this implies $k = t$ and we can append α to $\alpha \in S_r$ by $\alpha(1) := r$.

(iii) By (iv) σ can be written as a composition of cycles $\zeta_j := \zeta_{i(j)}$ with pairwise disjoint domains. And by (v) these cycles are uniquely determined. Hence this item (vi) is an immediate result of (iv) and (v).

(iv) By (iv) any permutation $\sigma \in S_n$ can be written as a composition of cycles $\sigma = \zeta_1 \dots \zeta_r$. And according to (1.16) any cycle ζ_i can be written as a composition of transpositions

$$\zeta_i \;=\; \prod_{j\in J(i)} \tau_{i,j}$$

Again, according to (1.16), any transposition $\tau_{i,j}$ can be written as a composition of adjacent transpositions

$$\tau_{i,j} \;=\; \prod_{k\in K(i,j)} \alpha_{i,j,k}$$

Altogether we can decompose σ into a - admittably *very* large - composition of adjacent cycles $\alpha_{i,j,k}$ by putting all this together.

(v) The implication (b) $\implies$ (a) is quite easy: pick up the cyclic decomposition $\varrho = \zeta_1 \dots \zeta_k$ as in (iii) and let $\xi_i := \pi\zeta_i\pi^{-1}$ for any $i \in 1 \dots r$. Then by (1.16) ξ_i is a cycle of the same length $\mathrm{ord}(\xi_i) = \mathrm{ord}(\zeta_i)$ again. And as π is bijective the cycles ξ_i are pairwise disjoint again. Now compute

$$\begin{aligned}\sigma \;&=\; \pi\varrho\pi^{-1} \;=\; \pi\zeta_1\zeta_2 \dots \zeta_k\pi^{-1}\\ &=\; \pi\zeta_1\pi^{-1}\pi\zeta_2\pi^{-1} \dots \pi\zeta_k\pi^{-1}\\ &=\; \xi_1\xi_2 \dots \xi_k\end{aligned}$$

That is we have found a cyclic decomposition of σ again. And by construction this decomposition satisfies the properties of (a). But as the cyclic decomposition of σ is unique (up to sequence, as we have seen in (ii)) (a) is true for *any* cyclic decomposition of σ.

The converse implication (a) $\implies$ (b) only requires little more effort: Let us abbreviate $\ell(i) := \mathrm{ord}(\zeta_i)$ the length of ζ_i. That is there are some numbers $a_{i,j} \in 1 \dots n$ such that ζ_i can be written as

$$\zeta_i \;=\; (a_{i,1}\;\; a_{i,2}\;\; \dots\;\; a_{i,\ell(i)})$$

And by assumption we have $\mathrm{ord}(\xi_{\alpha(i)}) = \mathrm{ord}(\zeta_i) = \ell(i)$ such that there also are numbers $b_{i,j} \in 1 \dots n$ such that $\xi_{\alpha(i)}$ can be written as

$$\xi_{\alpha(i)} \;=\; (b_{i,1}\;\; b_{i,2}\;\; \dots\;\; b_{i,\ell(i)})$$

As the domains of the ζ_i and the ξ_r are pairwise disjoint we obtain a disjoint union of sets (that compose the domain of ϱ)

$$D \;:=\; \bigcup_{i=1}^{k} \{\, a_{i,j} \mid j \in 1 \dots \ell(i) \,\}$$

And this enables us to define a permutation $\pi \in S_n$ by letting $\pi(a_{i,j}) := b_{i,j}$ for any $i \in 1 \dots k$ and $j \in 1 \dots \ell(i)$ and $\pi(a) := a$ for any $a \notin D$. Then by (1.16) it is clear that

$$\begin{aligned} \pi\zeta_i\pi^{-1} &= \pi(a_{i,1}\ a_{i,2}\ \dots\ a_{i,\ell(i)})\pi^{-1} \\ &= (\pi(a_{i,1})\ \pi(a_{i,2})\ \dots\ \pi(a_{i,\ell(i)})) \\ &= (b_{i,1}\ b_{i,2}\ \dots\ b_{i,\ell(i)}) \;=\; \xi_{\alpha(i)} \end{aligned}$$

Hence we find (reversing the computation in the case (b) $\Longrightarrow$ (a) above) that σ and ϱ are truly conjugates under π

$$\pi\varrho\pi^{-1} \;=\; \pi\left(\prod_{i=1}^{k}\zeta_i\right)\pi^{-1} \;=\; \prod_{i=1}^{k}(\pi\zeta_i\pi^{-1}) \;=\; \prod_{i=1}^{k}\xi_i \;=\; \sigma$$

□

Proof of (1.2) (commutativity):
We will now prove that in a commutative groupoid $(G, \circ)$ the order in which the elements $x_1, \dots, x_n \in G$ are multiplied has no impact on the result of the composition. That is for any permutation $\sigma \in S_n$ we have

$$x_{\sigma(1)}x_{\sigma(2)}\dots x_{\sigma(n)} \;=\; x_1x_2\dots x_n$$

As we have seen in (1.18.(iv)) any permutation $\sigma \in S_n$ can be expressed as a composition of adjacent transpositions

$$\sigma \;=\; \alpha_1\,\alpha_2\,\dots\,\alpha_s$$

We will now prove the claim by induction on the number of transpositions s. In case $s = 1$ we have to deal with one adjacent transposition, say $\alpha = (j\ j+1)$. Then we have

$$\prod_{i=1}^{n} x_{\alpha(i)} \;=\; x_1\dots x_{j-1}\,x_{j+1}\,x_j\,x_{j+2}\dots x_n$$

But by the commutativity rule (C) we can interchange x_{j+1} and x_j in this product to find $x_{\alpha(1)}x_{\alpha(2)}\dots x_{\alpha(n)} = x_1\dots x_jx_{j+1}\dots x_n$. In case $s \geq 2$ we let $\alpha := \alpha_1$ and $\varrho = \alpha_2\dots\alpha_s$. Then it is clear that $\sigma = \alpha\varrho$. And as in the case $s = 1$ resp. by induction hypothesis we get

$$\prod_{i=1}^{n} x_{\sigma(i)} \;=\; \prod_{i=1}^{n} x_{\alpha\varrho(i)} \;=\; \prod_{i=1}^{n} x_{\varrho(i)} \;=\; \prod_{i=1}^{n} x_i$$

□

Proof of (1.22):

(i) Let us denote the set $\Delta := \{(i,j) \in (1\dots n)^2 \mid i < j\}$ and the map $\delta : (1\dots n)^2 \to \mathbb{Z} : (i,j) \mapsto j - i$.

For $p, q \in \mathbb{N}$ we let $p \wedge q$ be the minimum and $p \vee q$ be the maximum of p and q. At last we define

$$\Sigma \;:\; \Delta \to \Delta \;:\; (i,j) \mapsto (\sigma(i) \wedge \sigma(j), \sigma(i) \vee \sigma(j))$$

Thereby Σ is well defined, since $1 \leq \sigma(i) \wedge \sigma(j) < \sigma(i) \vee \sigma(j) \leq n$. In fact Σ even is bijective, as we can explicitly give its inverse to be

$$\Sigma^{-1} \;:\; \Delta \to \Delta \;:\; (i,j) \mapsto (\sigma^{-1}(i) \wedge \sigma^{-1}(j), \sigma^{-1}(i) \vee \sigma^{-1}(j))$$

As Δ is finite it suffices to check $\Sigma^{-1}\Sigma = \mathbb{1}_\Delta$: let $(p,q) := \Sigma(i,j)$, then p and $q \in \{\, \sigma(i), \sigma(j) \,\}$ and $p < q$. Hence $\sigma^{-1}(p)$ and $\sigma^{-1}(q) \in \{\, i, j \,\}$, so ordering them we get $\Sigma^{-1}(p,q) = (i,j)$ again, which is the bijectivity of Σ. Also we easily compute

$$\begin{aligned} \delta\Sigma(i,j) &= \begin{cases} \sigma(j) - \sigma(i) \text{ if } \sigma(j) > \sigma(i) \\ \sigma(i) - \sigma(j) \text{ if } \sigma(j) < \sigma(i) \end{cases} \\ &= \big(\sigma(j) - \sigma(i)\big) \begin{cases} 1 \text{ if } \sigma(j) > \sigma(i) \\ -1 \text{ if } \sigma(j) < \sigma(i) \end{cases} \end{aligned}$$

After all these preparations we can proceed to the main computation: we use the fact that (due to the commutativity of $\mathbb{Z}$) the product can be permuted arbitrarily without changing its result. Here we have

$$\begin{aligned} \prod_{(i,j)\in\Delta} (j-i) &= \prod_{(i,j)\in\Delta} \delta(i,j) = \prod_{(p,q)\in\Sigma(\Delta)} \delta(i,j) \\ &= \prod_{(i,j)\in\Delta} \Sigma\delta(i,j) = (-1)^{I(\sigma)} \prod_{(i,j)\in\Delta} \big(\sigma(j) - \sigma(i)\big) \end{aligned}$$

And from here we are almost done, note that the product $\prod(j-i)$ is non-zero, as we always have $i < j$. Also $1/(-1)^{I(\sigma)} = (-1)^{I(\sigma)}$ as this number is either $+1$ or -1. Hence dividing by the product and $(-1)^{I(\sigma)}$ we finally get

$$(-1)^{I(\sigma)} = \frac{\prod_{(i,j)\in\Delta} \big(\sigma(j) - \sigma(i)\big)}{\prod_{(i,j)\in\Delta}(j-i)} = \prod_{(i,j)\in\Delta} \frac{\sigma(j) - \sigma(i)}{j-i}$$

(iv) Let us continue with the notation introduced in (i) above. Then we have already shown the following identity for any permutation σ

$$(-1)^{I(\sigma)} \prod_{(i,j)\in\Delta} (j-i) = \prod_{(i,j)\in\Delta} \big(\sigma(j) - \sigma(i)\big)$$

Using this identity for the composition $\varrho\sigma$ and the permutations σ and ϱ separately we can again compute

$$(-1)^{I(\varrho\sigma)} \prod_{(i,j)\in\Delta} (j-i) = \prod_{(i,j)\in\Delta} \big(\varrho\sigma(j) - \varrho\sigma(i)\big)$$

$$
\begin{aligned}
&= (-1)^{I(\sigma)} \prod_{(i,j)\in\Delta} \big(\varrho(j) - \varrho(i)\big) \\
&= (-1)^{I(\sigma)}(-1)^{I(\varrho)} \prod_{(i,j)\in\Delta} (j-i)
\end{aligned}
$$

Hence dividing by the product $\prod(j-i)$ we have established the homomorphism property of the signum, expressed in terms of (i):

$$
\begin{aligned}
\operatorname{sgn}(\varrho\sigma) &= (-1)^{I(\varrho\sigma)} = (-1)^{I(\sigma)}(-1)^{I(\varrho)} \\
&= (-1)^{I(\varrho)}(-1)^{I(\varrho)} = \operatorname{sgn}(\varrho)\operatorname{sgn}(\sigma)
\end{aligned}
$$

(iii) Consider the permutation $\tau = (a\ b)$ where (without loss of generality) $a < b$. Then it is easy to see, that τ has the following inversions

$$
\begin{aligned}
&\{\, (i,j) \in \Delta \mid \tau(i) > \tau(j) \,\} \\
&= \{\, (a, a+s) \mid 1 \le s \le b-a \,\} \cup \{\, (a+r, b) \mid 1 \le r < b-a \,\}
\end{aligned}
$$

In particular we get $I(\tau) = (b-a) + (b-a-1) = 2(b-a) - 1$ and thereby we get - using variant (i) of computing the signum

$$
\operatorname{sgn}(\tau) = (-1)^{I(\tau)} = (-1)^{2(b-a)-1} = \big((-1)^2\big)^{b-a}(-1)^{-1} = -1
$$

That is any transposition is an odd permutation! Thus, if $\sigma = \tau_1 \dots \tau_r$ is a composition of r transpositions, then the homomorphism property (iv) of the signum implies

$$
\operatorname{sgn}(\sigma) = \prod_{i=1}^{r} \operatorname{sgn}(\tau_i) = \prod_{i=1}^{r} (-1) = (-1)^r
$$

(ii) By (1.16) we know that any cycle ζ_i can be written as a composition of $\ell(i) - 1$ transpositions. Hence - by (iv) combined with (iii)

$$
\operatorname{sgn}(\sigma) = \operatorname{sgn}(\zeta_1 \dots \zeta_r) = \prod_{i=1}^{r} \operatorname{sgn}(\zeta_i) = \prod_{i=1}^{r} (-1)^{\ell(i)-1}
$$

And as the domains of the ζ_i are pairwise disjoint (1.14.(iv)) implies, that they are mutually commutative. Hence by (1.5) we find that any power $k \in \mathbb{N}$ of σ is just

$$
\sigma^k = \prod_{i=1}^{r} \zeta_i^k
$$

Also as $\operatorname{dom}(\zeta_i^k) \subseteq \operatorname{dom}(\zeta_i)$ (this is (1.14.(ii))) and the $\operatorname{dom}(\zeta_i)$ are pairwise disjoint we have (for any $a \in 1 \dots n$) $\sigma(a) = a$ if and only if $\zeta_i^k(a) = a$ for any $i \in 1 \dots r$. In particular we see the equivalence of

$$
\sigma^k = \mathbb{1} \iff \forall\, i \in 1 \dots r : \zeta_i^k = \mathbb{1}
$$

As ζ_i is a cycle its order is given to be $\ell(i) = \operatorname{ord}(v_i)$. Hence $\zeta_i^k = \mathbb{1}$ if and only if $\ell(i)$ divides k (by division with remainder again, write $k = m\ell(i) + r$ then $\zeta_i^k = (\zeta_i^{\ell(i)})^m \zeta_i^r = \zeta_i^r = \mathbb{1}$ iff $r = 0$).

Therefore

$$\sigma^k \;=\; \mathbb{1} \quad\Longleftrightarrow\quad \forall\, i \in 1 \dots r \;:\; \ell(i) \;\mid\; k$$

Now $\operatorname{ord}(\sigma) = k$ is the minimal number $1 \leq k \in \mathbb{N}$ such that $\sigma^k = \mathbb{1}$. And likewise $\operatorname{lcm}(\ell(1), \dots, \ell(r))$ is the minimal number that is divided, by all the $\ell(i)$. In particular both numbers are equal.

(v) By definition A_n is just the kernel of the group-homomorphism $\operatorname{sgn} : S_n \to \mathbb{Z}^*$. Therefore the first isomorphism theorem (of groups) yields

$$S_n \Big/ A_n \;\xrightarrow{\sim}\; \mathbb{Z}^* \;:\; \sigma A_n \mapsto \operatorname{sgn}(\sigma)$$

In particular these two sets have the same cardinality. Now use the theorem of Lagrange and (1.12.(i)) to compute

$$2 \;=\; \#\mathbb{Z}^* \;=\; \#S_n \Big/ \#A_n \;=\; \frac{\#S_n}{\#A_n} \;=\; \frac{n!}{\#A_n}$$

□

Proof of (1.29):

- The properties of ι are clear. Also it is straightforward to see, that for any $b \in \mathbb{Z}$ and $y \in S$ we have $(0,0) + (b,y) = (b,y)$ and $(1,0) \cdot (b,y) = (b,y)$ and likewise $(b,y) \cdot (1,0) = (b,y)$. Thus $(0,0)$ is the zero-element and $(1,0)$ the unit element of R. Also it can be checked without effort, that $(R,+)$ is a commutative group, as both $(\mathbb{Z},+)$ and $(S,+)$ are.

- In the next step we prove that S becomes a $\mathbb{Z}$-module under its own addition and the following scalar-multiplication: For any $x \in S$ and any $a \in \mathbb{Z}$ we define $ax \in S$ by distinguishing three cases: (1) If $a = 0$ then $ax := 0$, (2) If $a > 0$ we define $ax := x + x + \dots + x$ (a-times) and (3) If $a < 0$ and $\alpha := -a > 0$ we define $ax := (-x) + (-x) + \dots (-x)$ (α-times). Actually case (1) can be considered a sub-case of (2). Also we have defined $ax := (-\alpha)(-x)$, so actually (2) is the one and only relevant case, (3) can be reduced to (2). From this definition it is clear, that $1x = x$ and $(a+b)x = (ax) + (bx)$ already. Also $a(x+y) = (ax) + (ay)$ is plain to see, as $+$ is commutative. Now take a look at $a(bx) = bx + bx + \dots + bx$ (a-times). If we just write out $bx = x + x + \dots + x$ all the time, we see, that $a(bx)$ is the sum of ab-times x, this is it equals $a(bx) = (ab)x$. This is the last property we needed, for a $\mathbb{Z}$-module.

- With these properties at hand we may prove the distributivity rules for R: Consider any a, b, $c \in \mathbb{Z}$ and x, y, $z \in S$. For the sake of clarity let us write the tuples (a,x) as column vectors, instead, then we compute:

$$\begin{aligned}
\begin{pmatrix} a \\ x \end{pmatrix} \left(\begin{pmatrix} b \\ y \end{pmatrix} + \begin{pmatrix} c \\ z \end{pmatrix} \right) \;&=\; \begin{pmatrix} a \\ x \end{pmatrix} \begin{pmatrix} b+c \\ y+z \end{pmatrix} \\
&=\; \begin{pmatrix} a(b+c) \\ a(y+z) + (b+c)x + x(y+z) \end{pmatrix} \\
&=\; \begin{pmatrix} ab+ac \\ ay+az+bx+cx+xy+xz \end{pmatrix} \\
\begin{pmatrix} a \\ x \end{pmatrix} \begin{pmatrix} b \\ y \end{pmatrix} + \begin{pmatrix} a \\ x \end{pmatrix} \begin{pmatrix} c \\ z \end{pmatrix} \;&=\; \begin{pmatrix} ab \\ ay+bx+xy \end{pmatrix} \begin{pmatrix} ac \\ az+cx+xz \end{pmatrix}
\end{aligned}$$

$$= \begin{pmatrix} ab+ac \\ ay+bx+xy+az+cx+xy \end{pmatrix}$$

We just need to rearrange these 6 terms a little, which is allowed, since the addition on S is commutative, to find the identity of these expressions. So this is the distributivity rule of multiplication from the left. Multiplication from the right can be done in precisely the same way.

- Before we continue, we need another preliminary: Any semi-ring is a $\mathbb{Z}$-semi-algebra under its own multiplication and the scalar-multiplication introduced above. We have to verify the three compatibility properties (A) of the multiplication with the scalar-multiplication. We begin with $a \geq 0$ and $x, y \in S$. Then we compute $x(ay) = x(y+y+\cdots+y) = (xy+xy+\cdots+xy) = a(xy)$. That is we have verified the associativity $a(xy) = x(ay)$ for $a \in \mathbb{N}$. For $a < 0$ we have let $\alpha := -a \in \mathbb{N}$, then $ay = (-\alpha)(-y)$ and hence $x(ay) = x((-\alpha)(-y)) = (-\alpha)(x(-y)) = (-\alpha)(-xy) = a(xy)$. Thus we generally have $a(xy) = x(ay)$ for any $a \in \mathbb{Z}$. In exactly the same way, we see that $(ax)y = a(xy)$ for any $a \in \mathbb{Z}$ and $x, y \in S$. Let us summarize:

$$(ax)y \;=\; a(xy) \;=\; x(ay)$$

As with the associativity $(xy)z = x(yz)$ it is customary to omit the brackets in $(ax)y = a(xy)$, as both terms yield the same result. We will need these identities and $a(bx))(ab)x$ in the next step.

- It remains to check that the multiplication on R truly satisfies the properties of a ring: associativity, distributivity. Thus we start with a, b and $c \in \mathbb{Z}$ and x, y, $z \in S$ and head out for a series of computations:

$$\begin{aligned}
\left(\begin{pmatrix} a \\ x \end{pmatrix}\begin{pmatrix} b \\ y \end{pmatrix}\right)\begin{pmatrix} c \\ z \end{pmatrix} &= \begin{pmatrix} ab \\ ay+bx+xy \end{pmatrix}\begin{pmatrix} c \\ z \end{pmatrix} \\
&= \begin{pmatrix} abc \\ (ab)z+c(ay)+c(bx)+c(xy)+(ay)z+(bx)z+(xy)z \end{pmatrix} \\
&= \begin{pmatrix} abc \\ abz+cay+cbx+cxy+ayz+bxz+xyz \end{pmatrix} \\
\begin{pmatrix} a \\ x \end{pmatrix}\left(\begin{pmatrix} b \\ y \end{pmatrix}\begin{pmatrix} c \\ z \end{pmatrix}\right) &= \begin{pmatrix} a \\ x \end{pmatrix}\begin{pmatrix} bc \\ bz+cy+yz \end{pmatrix} \\
&= \begin{pmatrix} abc \\ a(bz)+a(cy)+a(yz)+(bc)x+x(bz)+x(cy)+x(yz) \end{pmatrix} \\
&= \begin{pmatrix} abc \\ abz+acy+ayz+bcx+bxz+cxy+xyz \end{pmatrix}
\end{aligned}$$

As the multiplication in $\mathbb{Z}$ is commutative we have $cay = acy$ and $cbx = bcx$. Therefore both of these expressions contain exactly the same 7 terms. And as the addition on S is commutative, we find that the sums are equal. This is the associativity of R.

□

Proof of (1.41):

- The statement $0 = -0$ is clear from $0+0=0$. And $a0 = 0$ follows from $a0 = a(0+0) = a0 + a0$. Likewise we get $0a = 0$. And from this an easy computation shows $(-a)b = -(ab)$, this computation reads as $ab + (-a)b = (a + (-a))b = 0b = 0$ (and $a(-b) = -(ab)$ follows analogously). Combining these two we find $(-a)(-b) = ab$, since $ab = -(-ab) = -((-a)b) = (-a)(-b)$.

- Next we will prove the general rule of distributivity: we start by showing that $(a_1 + \cdots + a_m)b = (a_1 b) + \cdots + (a_m b)$ by induction on m. The case $m = 1$ is clear and in the induction step we simply compute

$$\begin{aligned}\Big(a_1 + \cdots + a_m + a_{m+1}\Big)\, b &= \Big((a_1 + \cdots + a_m) + a_{m+1}\Big)\, b \\ = \left(\sum_{i=1}^{m} a_i\right) b + a_{m+1}b &= \left(\sum_{i=1}^{m} a_i b\right) + a_{m+1}b = \sum_{i=1}^{m+1} a_i b\end{aligned}$$

 Likewise it is clear, that $a(b_1 + \cdots + b_n) = (ab_1) + \cdots + (ab_n)$. And combining these two equations we find the generale rule

$$\begin{aligned}\left(\sum_{i=1}^{m} a_i\right)\left(\sum_{j=1}^{n} b_j\right) &= \sum_{j=1}^{n}\left(\sum_{i=1}^{m} a_i\right) b_j \\ &= \sum_{j=1}^{n}\left(\sum_{i=1}^{m} a_i b_j\right) \\ &= \sum_{i=1}^{m}\sum_{j=1}^{n} a_i b_j\end{aligned}$$

- Using induction on n we will now prove the generalization of the general law of distributivity. The case $n = 1$ is trivial (here $J = J(1)$ so there is nothing to prove). Thus consider the induction step by adding $J(0)$ to our list $J(1), \ldots, J(n)$ of index sets. Then clearly

$$\prod_{i=0}^{n}\sum_{j_i \in J(i)} a(i, j_i) = \left(\sum_{j_0 \in J(0)} a(0, j_0)\right)\left(\prod_{i=1}^{n}\sum_{j_i \in J(i)} a(i, j_i)\right)$$

 Hence we may use the induction hypothesis in the second term on the right hand side and the general law of distributivity (note that we use $J = J(1) \times \cdots \times J(n)$) again) to obtain

$$\begin{aligned}\prod_{i=0}^{n}\sum_{j_i \in J(i)} a(i, j_i) &= \left(\sum_{j_0 \in J(0)} a(0, j_0)\right)\left(\sum_{j \in J}\prod_{i=1}^{n} a_{i,j_i}\right) \\ &= \sum_{j_0 \in J(0)}\sum_{j \in J} a(0, j_0)\prod_{i=1}^{n} a(i, j_i)\end{aligned}$$

 To finish the induction step it suffices to note that the product of $a(0, j_0)$ with $\prod_{i=1}^{n} a(i, j_i)$ can be rewritten $\prod_{i=0}^{n} a(i, j_i)$ (due to the associativity of the multiplication). And the two sums over $j(0) \in J(0)$ resp. over $j \in J$ can be composed to a single sum over $(j_0, j) \in J(0) \times J$. Thas is we

have obtained the claim

$$\prod_{i=0}^{n} \sum_{j_i \in J(i)} a(i,j_i) \;=\; \sum_{(j_0,j)\in J(0)\times J} \prod_{i=0}^{n} a(i,j_i)$$

- Thus we have arrived at the binomial rule, which will be proved by induction on n. In the case $n=0$ we have $(a+b)^0 = 1 = 1\cdot 1 = a^0 b^{0-0}$. Thus we commence with the induction step

$$\begin{aligned}
& (a+b)^{n+1} \;=\; (a+b)^n (a+b) \\
=\;& \left(\sum_{k=0}^{n} \binom{n}{k} a^k b^{n-k} \right) (a+b) \\
=\;& \sum_{k=0}^{n} \binom{n}{k} a^{k+1} b^{n-k} + \sum_{k=0}^{n} \binom{n}{k} a^k b^{(n+1)-k} \\
=\;& \sum_{k=1}^{n+1} \binom{n}{k-1} a^k b^{(n+1)-k} + \sum_{k=0}^{n} \binom{n}{k} a^k b^{(n+1)-k} \\
=\;& \binom{n}{n} a^{n+1} b^0 + \sum_{k=1}^{n} \left(\binom{n}{k-1} + \binom{n}{k} \right) a^k b^{(n+1)-k} + \binom{n}{0} a^0 b^{n+1} \\
=\;& \binom{n+1}{0} a^0 b^{n+1} + \sum_{k=1}^{n} \binom{n+1}{k} a^k b^{(n+1)-k} + \binom{n+1}{n+1} a^{n+1} b^0 \\
=\;& \sum_{k=0}^{n+1} \binom{n}{k} a^k b^{n-k}
\end{aligned}$$

- It remains to verify the polynomial rule, which will be done by induction on k. The case $k=1$ is clear again, and the case $k=2$ is the ordinary binomial rule. Thus consider the induction step

$$\begin{aligned}
& \Big(a_1 + \cdots + a_k + a_{k+1} \Big)^n \\
=\;& \Big(a_{k+1} + (a_1 + \cdots + a_k) \Big)^n \\
=\;& \sum_{\alpha_{k+1}=0}^{n} \binom{n}{\alpha_{k+1}} a_{k+1}^{\alpha_{k+1}} (a_1 + \cdots + a_k)^{n-\alpha_{k+1}} \\
=\;& \sum_{\alpha_{k+1}=0}^{n} \binom{n}{\alpha_{k+1}} a_{k+1}^{\alpha_{k+1}} \left(\sum_{|\alpha|=n-\alpha_{k+1}} \binom{n-\alpha_{k+1}}{\alpha} a^\alpha \right) \\
=\;& \sum_{\alpha_{k+1}=0}^{n} \sum_{|\alpha|=n-\alpha_{k+1}} \binom{n}{\alpha_{k+1}} \binom{n-\alpha_{k+1}}{\alpha} a^\alpha a_{k+1}^{\alpha_{k+1}} \\
=\;& \sum_{|(\alpha,\alpha_{k+1})|=n} \binom{n}{(\alpha,\alpha_{k+1})} (a, a_{k+1})^{(\alpha,\alpha_{k+1})}
\end{aligned}$$

□

Proof of (1.44):
Let us regard the polynomial ring $R = \mathbb{Z}[x,y]$ in two variables x and y. As R is commutative it is clear,

that $(x+y)^n = (x+y)^k(x+y)^{n-k}$. By the binomial rule (1.41) we may evaluate these terms to

$$\begin{aligned}\sum_{r=0}^{n}\binom{n}{r}x^r y^{n-r} &= \left(\sum_{i=0}^{k}\binom{k}{i}x^i y^{k-i}\right)\left(\sum_{j=0}^{n-k}\binom{n-k}{j}x^j y^{n-k-j}\right)\\ &= \sum_{r=0}^{n}\sum_{i+j=r}\binom{k}{i}\binom{n-k}{j}x^{i+j}y^{k-i+n-k-j}\\ &= \sum_{r=0}^{n}\sum_{i+j=r}\binom{k}{i}\binom{n-k}{j}x^r y^{n-r}\end{aligned}$$

where we also used the general rule of distributivity. Now we may compare coefficients (which is allowed by construction of R) to find our claim (as $j = r - i$)

$$\binom{n}{r} = \sum_{i+j=r}\binom{k}{i}\binom{n-k}{j} = \sum_{i=0}^{r}\binom{k}{i}\binom{n-k}{r-i}$$

□

Proof of (1.45):

We now prove the equivalences for integral rings: For (a) $\implies$ (b') we are given a, b and $c \in R$ with $a \neq 0$ and $ba = ca$. Then we get $(c-b)a = 0$ which is $c - b \in \text{ZD}(R)$. By assumption (a) this implies $c - b = 0$ and hence $b = c$. Now the implication (b') $\implies$ (c') is trivial, just let $c = 1$. And for the final step (c') $\implies$ (a) we consider $0 \neq b \in R$ such that $ab = 0$. Then $(a+1)b = ab + b = b$ such that by assumption (c') we get $a + 1 = 1$ and hence $a = 0$. Thereby we have obtained $\text{ZD}(R) \subseteq \{0\}$ and the converse inclusion is clear.

Next we consider (a) $\implies$ (b), again we are given a, b and $c \in R$ with $a \neq 0$ and $ab = ac$. This yields $a(c-b) = 0$ and as $a \neq 0$ we have $a \notin \text{ZD}(R)$ such that $a \in \text{NZD}(R)$. Hence $c - b = 0$ which is $b = c$. The implication (b) $\implies$ (c) is clear again, just let $c = 1$. And for (c) $\implies$ (a) we consider $0 \neq a \in R$ such that $ab = 0$. Then $a(b+1) = ab + a = a$. By assumption (c) this implies $b + 1 = 1$ and hence $b = 0$. Therefore $R \setminus \{0\} \subseteq \text{NZD}(R)$ which is $R \setminus \{0\} = \text{NZD}(R)$ and hence $\text{ZD}(R) = \{0\}$. □

Proof of (1.47):

(i) The equality of sets $\text{NZD}(R) = R \setminus \text{ZD}(R)$ is immediately clear from the definition: The negation of the formula $\exists\, b \in R : (b \neq 0) \wedge (ab = 0)$ is just $\forall\, b \in R : ab = 0 \implies b = 0$.

(ii) If $a \in \text{NIL}(R)$ then we choose $k \in \mathbb{N}$ minimal such that $a^k = 0$. Suppose $k = 0$, then $0 = a^0 = 1$ which would mean that $R = 0$ has been the zero-ring. Thus we have $k \geq 1$ and may hence define $b := a^{k-1} \neq 0$. Then $ab = a^k = 0$ and hence $a \in \text{ZD}(R)$, which proves $\text{NIL}(R) \subseteq \text{ZD}(R)$. And if $ab = 0$, then $a \in R^{ast}$ would imply $b = a^{-1}0 = 0$. Thus if $a \in \text{ZD}(R)$ then $a \notin R^*$ which also proves $\text{ZD}(R) \subseteq R \setminus R^*$.

(iii) It is clear that $1 \in \text{NZD}(R)$, as $1b = b$. Now suppose a and $b \in \text{NZD}(R)$ and consider any $c \in R$. If $(ab)c = 0$ then (because of the associativity $a(bc) = 0$ and as $a \in \text{NZD}(R)$ this implies $bc = 0$. As $b \in \text{NZD}(R)$ this now implies $c = 0$ which means $ab \in \text{NZD}(R)$.

(iv) It is clear that $1 \in R^*$ - just choose $b = 1$. Now the associativity and existence of a neutral element $e = 1$ is immediately inherited from (the multiplication) of R. Thus consider $a \in R^*$, by definition

there is some $b \in R$ such that $ab = 1 = ba$. Hence we also have $b \in R^*$ and thereby b is the inverse element of a in R^*.

(v) " $\Longleftarrow$ " first suppose $0 = 1 \in R$ then we would have $R = 0$ and hence $R \setminus \{0\} = \emptyset$ and $R^* = R \neq \emptyset$, in contradiction to the assumption $R^* = R \setminus \{0\}$. Thus we get $0 \neq 0$. If now $0 \neq a \in R$ then $a \in R^*$ by assumption and hence there is some $b \in R$ such that $ab = 1 = ba$. But this also is property (F) of skew-fields. " $\Longrightarrow$ " if $0 \neq a \in R$ then - as R is a skew field - there is some $b \in R$ such that $ab = 1 = ba$. But this already is $a \in R^*$ and hence $R \setminus \{0\} \subseteq R^*$. Conversely consider $a \in R^*$, that is $ab = 1 = ba$ for some $b \in R$. Suppose $a = 0$, then $1 = ab = 0 \cdot b = 0$ and hence $0 = 1$, a contradiction. Thus $a \neq 0$ and this also proves $R^* \subseteq R \setminus \{0\}$.

(vi) Consider a and $b \in \text{NIL}(R)$ such that $a^k = 0$ and $b^l = 0$. Then we will prove $a + b \in \text{NIL}(R)$ by demonstrating $(a+b)^{k+l} = 0$, via

$$\begin{aligned}
(a+b)^{k+l} &= \sum_{i=0}^{k+l} \binom{k+l}{i} a^i b^{k+l-i} \\
&= \sum_{i=0}^{k} \binom{k+l}{i} a^i b^{l+(k-i)} + \sum_{j=1}^{l} \binom{k+l}{k+j} a^{k+j} b^{l-j} \\
&= b^l \sum_{i=0}^{k} \binom{k+l}{i} a^i b^{k-i} + a^k \sum_{j=1}^{l} \binom{k+l}{k+j} a^j b^{l-j} \\
&= 0 + 0 \;=\; 0
\end{aligned}$$

And if $c \in R$ is an arbitrary element, then also $(ca)^k = c^k a^k = c^k 0 = 0$ such that $ca \in \text{NIL}(R)$. As a has been chosen arbitarily, this implies $R\,(\text{NIL}(R)) \subseteq R$ and hence $\text{NIL}(R) \trianglelefteq_{\text{i}} R$ is an ideal.

(vii) Consider x and $y \in \text{ann}(b)$. Then it is clear that $(x+y)b = xb + yb = 0 + 0 = 0$ and hence $x + y \in \text{ann}(b)$. And if $a \in R$ is arbitrary then $(ax)b = a(bx) = a0 = 0$ such that $ax \in \text{ann}(b)$. In particular $-x = (-1)x \in \text{ann}(b)$ and hence $\text{ann}(b)$ is a sub-module of R.

(viii) Let $u \in R^*$ and $a \in R$ with $a^n = 0$, then we can verify the formula for the inverse of $u + a$ in straightforward computation (see below). And in particular we found $u + a \in R^*$. But as a has been an arbitrary nilpotent, this has truly been $u + \text{NIL}(R) \subseteq R^*$.

$$\begin{aligned}
& (a+u) \sum_{k=0}^{n-1} (-1)^k a^k u^{-k-1} \\
= \;& \sum_{k=0}^{n-1} (-1)^k a^{k+1} u^{-(k+1)} + \sum_{k=0}^{n-1} (-1)^k a^k u^{-k} \\
= \;& \sum_{k=1}^{n} (-1)^{k-1} a^k u^{-k} \sum_{k=0}^{n-1} (-1)^k a^k u^{n-(k-1)} \\
= \;& (-1)^{n-1} a^n u^{-n} + (-1)^0 a^0 u^{-0} \;=\; 1
\end{aligned}$$

(ix) We identify R with the subset $\{\, a/1 \mid a \in R \,\} \subseteq F$. If $E = F$ then it is clear that $R \subseteq F = E$. Conversely suppose $R \subseteq E$, any $a/b \in F$ is composed of a, $b \in R$ with $b \neq 0$. As $R \subseteq E$ and $b \neq 0$ we have $b^{-1} \in E$ and therefore $a/b = ab^{-1} \in E$. But as this is true for any $a/b \in F$ we find $F \subseteq E$ and therefore $E = F$.

□

Proof of (1.52):

- ($\star$ = semi-ring) as any P_i is a sub-semiring we have $0 \in P_i$ and hence $0 \in \bigcap_i P_i$ again. Now consider $a, b \in \bigcap_i P_i$ that is $a, b \in P_i$ for any $i \in I$. As any P_i is a sub-semiring this implies that $a+b$, ab and $-a \in P_i$ (for any $i \in I$). And thereby $a+b$, ab and $-a \in \bigcap_i P_i$ again.

- ($\star =$ ring) in complete analogy we have $1 \in P_i$ (for any $i \in I$, as any P_i has been assumed to be a sub-ring. Hence we also get $1 \in \bigcap_i P_i$.

- ($\star =$ (skew)field) consider $0 \neq a \in \bigcap_i P_i$. That is $a \in P_i$ for any $i \in I$ and as any P_i is a subfield we get $a^{-1} \in P_i$ such that $a^{-1} \in \bigcap_i P_i$.

- ($\star =$ (left)ideal) consider any $b \in R$ and $a \in \bigcap_i P_i$ - that is $a \in P_i$ for any $i \in I$. As P_i is a left-ideal we find $ba_i \in P_i$ again and hence $ba \in \bigcap_i P_i$. In the case of ideals P_i we analogously find $ab \in \bigcap_i P_i$.

- Note that thereby the generation of $\star$ is well-defined - the set of all $\star$s containing X is non-empty, as R itself is a $\star$ (e.g. R is an ideal of R). And by the lemma we have just proved, the intersection is a $\star$ again.

□

Proof of (1.55):

- Let us denote the set $\mathfrak{a} := \{\sum_i a_i x_i\}$ of which we claim $\mathfrak{a} = \langle X \rangle_{\mathsf{m}}$. First of all it is clear that $X \subseteq \mathfrak{a}$, as $x = 1x \in \mathfrak{a}$ for any $x \in X$. Further it is clear that $\mathfrak{a} \leq_{\mathsf{m}} R$ is a left-ideal of R: choose any $x \in X$, then $0 = 0 \cdot x \in \mathfrak{a}$, and if $b \in R$, $x = a_1 x_1 + \cdots + a_m x_m$ and $y = b_1 y_1 + \cdots + b_n y_n \in \mathfrak{a}$ then $bx = (ba_1)x_1 + \cdots + (ba_m)x_m \in \mathfrak{a}$ and $x + y = a_1 x_1 + \cdots + a_m x_m + b_1 y_1 + \cdots + b_n y_n \in \mathfrak{a}$. Thus by definition of $\langle X \rangle_{\mathsf{m}}$ we get $\langle X \rangle_{\mathsf{m}} \subseteq \mathfrak{a}$. Now suppose $\mathfrak{b} \leq_{\mathsf{m}} R$ is any left-ideal of R containing $X \subseteq \mathfrak{b}$, Then for any $a_i \in R$ and any $x_i \in X \subseteq \mathfrak{b}$ we get $a_i x_i \in \mathfrak{b}$ and hence $\sum_i a_i x_i \in \mathfrak{b}$, too. That is $\mathfrak{a} \subseteq \mathfrak{b}$, and as $\mathfrak{b}$ has been arbitrary this means $\mathfrak{a} \subseteq \langle X \rangle_{\mathsf{m}}$, by the definition of $\langle X \rangle_{\mathsf{m}}$.

- Denote the set $P := \{\sum_i \prod_j x_{i,j}\}$ of which we claim $P = \langle X \rangle_{\mathsf{s}}$ again. Trivially we have $X \subseteq P$ and further it is clear that $P \leq_{\mathsf{s}} R$ is a sub-semi-algebra of R: choose any $x \in X$, then $0 = 0 \cdot x \in P$, and if $a = \sum_i \prod_j x_{i,j}$ and $b = \sum_k \prod_l y_{k,l}$, then $-a = \sum_i (-x_{i,1}) \prod_{j \geq 2} x_{i,j} \in P$, $a + b = \sum_i \prod_j x_{i,j} + \sum_k \prod_l y_{k,l} \in P$ and by general distributivity also $ab = \sum_i \sum_j (\prod_j x_{i,j} \prod_l y_{k,l}) \in P$. Thus by definition of $\langle X \rangle_{\mathsf{s}}$ we get $\langle X \rangle_{\mathsf{s}} \subseteq P$. Now suppose $Q \leq_{\mathsf{s}} R$ is any sub-semi-ring of R. Then for any and any $x \in X \subseteq Q$ we also get $-x \in Q$ and hence $\pm X \subseteq Q$. Now consider any $x_{i,j} \in \pm X \subseteq Q$ then $\prod_j x_{i,j} \in Q$ and hence $\prod_j x_{i,j} \in Q$. That is $P \subseteq Q$, and as Q has been arbitrary, this means $P \subseteq \langle X \rangle_{\mathsf{s}}$, by definition of $\langle X \rangle_{\mathsf{s}}$.

- By construction $P := \langle X \cup \{1\} \rangle_{\mathsf{s}}$ is a sub-semiring containing 1, in other words a sub-ring. And as $X \subseteq P$ this implies $\langle X \rangle_{\mathsf{r}} \subseteq P$. And as any sub-ring $Q \leq_{\mathsf{r}} R$ contains 1 we get $X \subseteq Q \implies X \cup \{1\} \subseteq Q \implies P \subseteq Q$. This also proves $\langle X \rangle_{\mathsf{r}} \subseteq P$, as Q has been arbitrary.

- Now suppose R is a field, and let $P := \{ ab^{-1} \mid a, b \in \langle X \rangle_{\mathsf{r}}, b \neq 0 \}$. First of all $0 = 0 \cdot 1^{-1}$ and $1 = 1 \cdot 1^{-1} \in P$. And if ab^{-1} and $cd^{-1} \in P$, then we get $(ab^{-1} + cd^{-1} = (ad + bc)(bd)^{-1} \in P$

and $(ab^{-1})(cd^{-1}) = (ab)(cd)^{-1} \in P$. And if $ab^{-1} \neq 0$ then we in particular have $a \neq 0$ and hence $(ab^{-1})^{-1} = ba^{-1} \in P$. Clearly $X \subseteq P$, as even $X \subseteq \langle X \rangle_{\mathfrak{r}}$. Altogether P is a field containing X and hence $\langle X \rangle_{\mathfrak{f}} \subseteq P$. And if conversely $Q \subseteq R$ is a field containing X, then $\langle X \rangle_{\mathfrak{r}} \subseteq Q$. Thus is $a, b \in Q$ with $b \neq 0$ then $b^{-1} \in Q$ and hence $ab^{-1} \in Q$, as Q is a field. But this proves $P \subseteq Q$ and thus $P \subseteq \langle X \rangle_{\mathfrak{f}}$.

□

Proof of (1.56):

We first have to prove, that $\mathfrak{a} \cap \mathfrak{b}$, $\mathfrak{a} + \mathfrak{b}$ and $\mathfrak{a}\,\mathfrak{b}$ truly are ideals of R. In the case of $\mathfrak{a} \cap \mathfrak{b}$ this has already been done in (1.52). For $\mathfrak{a} + \mathfrak{b}$ it is clear that $0 = 0 + 0 \in \mathfrak{a} + \mathfrak{b}$. and if $a + b$ and $a' + b' \in \mathfrak{a} + \mathfrak{b}$ then also $(a + b) + (a' + b') = (a + a') + (b + b') \in \mathfrak{a} + \mathfrak{b}$ and $-(a + b) = (-a) + (-b) \in \mathfrak{a} + \mathfrak{b}$. Thus consider any $f \in R$, as $\mathfrak{a}$ and $\mathfrak{b}$ are ideals we have fa, $af \in \mathfrak{a}$ and fb, $bf \in \mathfrak{b}$ again. Hence we get $f(a + b) = (fa) + (fb)$ and $(a + b)f = (af) + (bf) \in \mathfrak{a} + \mathfrak{b}$. Likewise $0 = 0 \cdot 0 \in \mathfrak{a}\,\mathfrak{b}$. And if $f = \sum_i a_i b_i$ and $g = \sum_j c_j d_j \in \mathfrak{a}\,\mathfrak{b}$ then it is clear from the definition that $f + g \in \mathfrak{a}\,\mathfrak{b}$. Further $-f = \sum_i (-a_i) b_i \in \mathfrak{a}\,\mathfrak{b}$ and for any arbitrary $h \in R$ we also get $hf = \sum_i (ha_i) b_i$ and $fh = \sum_i a_i (b_i h) \in \mathfrak{a}\,\mathfrak{b}$ by the same reasoning as for $\mathfrak{a} + \mathfrak{b}$.

Thus it remains to prove the chain of inclusions $\mathfrak{a}\,\mathfrak{b} \subseteq \mathfrak{a} \cap \mathfrak{b} \subseteq \mathfrak{a} \subseteq \mathfrak{a} + \mathfrak{b}$. Hereby $\mathfrak{a} \subseteq \mathfrak{a} + \mathfrak{b}$ is clear by taking $b = 0$ in $a + b \in \mathfrak{a} + \mathfrak{b}$. And $\mathfrak{a} \cap \mathfrak{b} \subseteq \mathfrak{a}$ is true trivially. Thus it only remains to verify $\mathfrak{a}\,\mathfrak{b} \subseteq \mathfrak{a} \cap \mathfrak{b}$. That is we consider $f = \sum_i a_i b_i \in \mathfrak{a}\,\mathfrak{b}$. Since $a_i \in \mathfrak{a}$ and $\mathfrak{a}$ is an ideal we have $a_i b_i \in \mathfrak{a}$ and hence even $f \in \mathfrak{a}$. Likewise we can verify $f \in \mathfrak{b}$ such that $f \in \mathfrak{a} \cap \mathfrak{b}$ as claimed. □

Proof of (1.57):

The associativity of $\cap$ is clear (from the associativity of the locical *and*). The associativity of ideals $(\mathfrak{a} + \mathfrak{b}) + \mathfrak{c} = \mathfrak{a} + (\mathfrak{b} + \mathfrak{c})$ is immediate from the associativity of elements $(a + b) + c = a + (b + c)$. The same is true for the commutativity of $\cap$ and $+$. Next we prove $(\mathfrak{a}\,\mathfrak{b})\,\mathfrak{c} \subseteq \mathfrak{a}\,(\mathfrak{b}\,\mathfrak{c})$. That is we are given an element of $(\mathfrak{a}\,\mathfrak{b})\,\mathfrak{c}$ which is of the form

$$\sum_{j=1}^{n} \left(\sum_{i=1}^{m} a_{i,j} b_{i,j} \right) c_j \;=\; \sum_{i=1}^{m} \sum_{j=1}^{n} a_{i,j} (b_{i,j} c_j)$$

For some $a_{i,j} \in \mathfrak{a}$, $b_{i,j} \in \mathfrak{b}$ and $c_j \in \mathfrak{c}$. However from the latter representation it is clear that this element is also contained in $\mathfrak{a}\,(\mathfrak{b}\,\mathfrak{c})$, which establishes the inclusion. The converse inclusion can be shown in complete analogy, which proves the associativity $(\mathfrak{a}\,\mathfrak{b})\,\mathfrak{c} = \mathfrak{a}\,(\mathfrak{b}\,\mathfrak{c})$. And if R is commutative the commutativity of ideals $\mathfrak{a}\,\mathfrak{b} = \mathfrak{b}\,\mathfrak{a}$ is immediate from the commuativity of the elements $ab = ba$. Thus it remains to check the distributivity

$$\mathfrak{a}\,(\mathfrak{b} + \mathfrak{c}) \;=\; (\mathfrak{a}\,\mathfrak{b}) + (\mathfrak{a}\,\mathfrak{c})$$

For the inclusion " $\supseteq$ " we are given elements $a_i \in \mathfrak{a}$, $b_i \in \mathfrak{b}$ and $c_i \in \mathfrak{c}$ (where $i \in 1 \ldots m$) such that $\sum_i a_i (b_i + c_i) \in \mathfrak{a}\,(\mathfrak{b} + \mathfrak{c})$. But it is already obvious that $\sum_i a_i (b_i + c_i) = \sum_i a_i b_i + \sum_i a_i c_i \in (\mathfrak{a}\,\mathfrak{b}) + (\mathfrak{a}\,\mathfrak{c})$. And for the converse inclusion "$\subseteq$" we are given a_i, $a'_j \in \mathfrak{a}$, $b_i \in \mathfrak{b}$ and $c_j \in \mathfrak{c}$ such that $\sum_i a_i b_i + \sum_j a'_j c_j \in (\mathfrak{a}\,\mathfrak{b}) + (\mathfrak{a}\,\mathfrak{c})$. This however can be rewritten into the form $\sum_i a_i b_i + \sum_j a'_j c_j = \sum_i a_i (b_i + 0) + \sum_j a'_j (0 + c_j) \in \mathfrak{a}\,(\mathfrak{b} + \mathfrak{c})$. In complete analogy it can be shown, that $(\mathfrak{a} + \mathfrak{b})\,\mathfrak{c} = (\mathfrak{a}\,\mathfrak{c}) + (\mathfrak{b}\,\mathfrak{c})$. □

Proof of (1.59):

By assumption we have $\mathfrak{a} = \langle X \rangle_{\mathfrak{i}}$ and $\mathfrak{b} = \langle Y \rangle_{\mathfrak{i}}$, in particular $X \subseteq \mathfrak{a}$ and $Y \subseteq \mathfrak{b}$. Hence we get

$X \cup Y \subseteq \mathfrak{a} \cup \mathfrak{b} \subseteq \mathfrak{a} + \mathfrak{b}$ and therefore $\langle X \cup Y \rangle_{\mathfrak{i}} \subseteq \mathfrak{a} + \mathfrak{b}$ (as $\mathfrak{a} + \mathfrak{b}$ is an ideal of R). For the converse inclusion we regard $f = \sum_i a_i x_i b_i \in \mathfrak{a}$ and $g = \sum_j c_j y_j d_j$ (note that this representation with $x_i \in X$ and $y_j \in Y$ is allowed, due to (1.55)). And hence we get $f + g = \sum_i a_i x_i b_i + \sum_j c_j y_j d_j \in \langle X \cup Y \rangle_{\mathfrak{i}}$. Together we have found $\mathfrak{a} + \mathfrak{b} = \langle X \cup Y \rangle_{\mathfrak{i}}$. For $\mathfrak{a}\,\mathfrak{b} = \langle X\,Y \rangle_{\mathfrak{i}}$ we have assumed R to be commutative. The one incluion is clear: as $X \subseteq \mathfrak{a}$ and $Y \subseteq \mathfrak{b}$ we trivially have $X\,Y \subseteq \mathfrak{a}\,\mathfrak{b}$. And as $\mathfrak{a}\,\mathfrak{b}$ is an ideal of R this implies $\langle X\,Y \rangle_{\mathfrak{i}} \subseteq \mathfrak{a}\,\mathfrak{b}$. For the converse inclusion we regard $f \in \mathfrak{a}$ and $g \in \mathfrak{b}$ as above. Then $fg = \sum_i \sum_j a_i b_i x_i y_j c_j d_j \in \langle X\,Y \rangle_{\mathfrak{i}}$ (due to the commutativity of R) which also establishes $\langle X\,Y \rangle_{\mathfrak{i}} = \mathfrak{a}\,\mathfrak{b}$. □

Proof of (1.60):

(i) First of all it is clear that $\mathfrak{b} \setminus \mathfrak{a} \subseteq \mathfrak{b}$. And hence we find $\langle \mathfrak{b} \setminus \mathfrak{a} \rangle_{\mathfrak{i}} \subseteq \langle \mathfrak{b} \rangle_{\mathfrak{i}} = \mathfrak{b}$ (as $\mathfrak{b}$ is an ideal already). Thus we have proved

$$\langle \mathfrak{b} \setminus \mathfrak{a} \rangle_{\mathfrak{i}} \quad \subseteq \quad \mathfrak{b}$$

Now fix any $b \in \mathfrak{b} \setminus \mathfrak{a}$ (this is possible by assumption $\mathfrak{a} \subset \mathfrak{b}$) and consider any $a \in \mathfrak{a}$. Then $a - b \in \mathfrak{b}$ but $a - b \notin \mathfrak{a}$ (else let $\alpha := a - b \in \mathfrak{a}$, then $b = a - \alpha \in \mathfrak{a}$, a contradiction). Thus $a - b \in \mathfrak{b} \setminus \mathfrak{a}$ and hence $a = b + (a - b) \in \langle \mathfrak{b} \setminus \mathfrak{a} \rangle_{\mathfrak{i}}$. As a has been arbitrary this yields $\mathfrak{a} \subseteq \langle \mathfrak{b} \setminus \mathfrak{a} \rangle_{\mathfrak{i}}$ and thereby we have also proved the converse inclusion

$$\mathfrak{b} \;=\; \mathfrak{a} \cup (\mathfrak{b} \setminus \mathfrak{a}) \;\subseteq\; \mathfrak{a} \cup \langle \mathfrak{b} \setminus \mathfrak{a} \rangle_{\mathfrak{i}} \;=\; \langle \mathfrak{b} \setminus \mathfrak{a} \rangle_{\mathfrak{i}}$$

(ii) By (1.55) the ideal generated by the union of the $\mathfrak{a}_i$ consists of finite sums of elements of the form $a_i x_i b_i$ where $a_i, b_i \in R$ and $x_i \in \mathfrak{a}_i$. But as $\mathfrak{a}_i$ is an ideal we get $a_i x_i b_i \in \mathfrak{a}_i$ already. And conversely any finite sum of elements $x_i \in \mathfrak{a}_i$ can be realized, by taking $a_i = b_i = 1$.

(iii) Here we just rewrote the the equality in (ii) in several ways: given a sum $\sum_{i \in I} a_i$ where $a_i \in \mathfrak{a}_i$ and $\Omega := \{\, i \in I \mid a_i \neq 0 \,\}$ is finite then $\sum_{i \in I} a_i = \sum_{i \in \Omega} a_i$ by definition of arbitrary sums. And likewise this is just $\sum_k a_k$ where $n := \#\Omega$, $\Omega = \{\, i(1), \ldots, i(n) \,\}$ and $a_k = a_{i(k)}$.

(iv) The general distributivity rule can be seen by a straightforward computation using the general rules of distributivity and associativity. First note that by definition and (iii) we have

$$\sum_{i \in I} \mathfrak{a}_i\,\mathfrak{b} \;=\; \left\{ \sum_{i \in \Omega} \left(\sum_{k=1}^{n(i)} a_{i,k} b_{i,k} \right) \;\middle|\; a_{i,k} \in \mathfrak{a}_i,\; b_{i,k} \in \mathfrak{b} \right\}$$

Now let $n := \max\{\, n(i) \mid i \in \Omega \,\}$ and for any $k > n(i)$ let $a_{i,k} := 0 \in \mathfrak{a}_i$. Then we may rewrite the latter set in the form

$$\sum_{i \in I} \mathfrak{a}_i\,\mathfrak{b} \;=\; \left\{ \sum_{k=1}^{n} \sum_{i \in \Omega} a_{i,k} b_{i,k} \;\middle|\; a_{i,k} \in \mathfrak{a}_i,\; b_{i,k} \in \mathfrak{b} \right\}$$

Let us now regart the other set involved. Again we will compute what this set means explictly - and thereby we will find the same identity as the one wh have just proved

$$\left(\sum_{i \in I} \mathfrak{a}_i \right) \mathfrak{b} \;=\; \left\{ \sum_{k=1}^{n} \left(\sum_{i \in \Omega(k)} a_{i,k} \right) b_k \;\middle|\; a_{i,k} \in \mathfrak{a}_i,\; b_k \in \mathfrak{b} \right\}$$

Then (in analogy to the above) we take $\Omega := \Omega(1) \cup \cdots \cup \Omega(n)$, $a_{i,k} := 0$ for $i \notin \Omega(k)$ and

$b_{i,k} := b_k$. Then this turns into

$$\left(\sum_{i\in I}\mathfrak{a}_i\right)\mathfrak{b} \;=\; \left\{\sum_{k=1}^{n}\sum_{i\in\Omega} a_{i,k}b_{i,k} \;\middle|\; a_{i,k}\in\mathfrak{a}_i,\; b_{i,k}\in\mathfrak{b}\right\}$$

□

Proof of (1.61):

(i) (a) $\Longrightarrow$ (b): $1 \in R = \mathfrak{a}+\mathfrak{b} = \{\, a+b \mid a\in\mathfrak{a}, b\in\mathfrak{b}\,\}$ is clear. Hence there are $a'\in\mathfrak{a}$ and $b\in\mathfrak{b}$ such that $1 = a'+b$. Now let $a := -a' \in \mathfrak{a}$ then $1 = (-a)+b$ and hence $b = 1+a \in (1+\mathfrak{a})\cap\mathfrak{b}$. (b) $\Longrightarrow$ (c): let $b\in(1+\mathfrak{a})\cap\mathfrak{b}$, that is there is some $a'\in\mathfrak{a}$ such that $b = 1+a'$. Again we let $a := -a' \in \mathfrak{a}$, then $a+b = 1$. (c) $\Longrightarrow$ (a): by the same reasoning as before we find $1 = a+b \in \mathfrak{a}+\mathfrak{b}$. And as $\mathfrak{a}+\mathfrak{b}$ is an ideal of R, this implies $\mathfrak{a}+\mathfrak{b} = R$.

(ii) As $\mathfrak{a}$ and $\mathfrak{b}$ are coprime there are some $a\in\mathfrak{a}$ and $b\in\mathfrak{b}$ such that $a+b=1$ - diue to (i). Using these we compute

$$\begin{aligned}
1 \;&=\; 1^{i+j} \;=\; (a+b)^{i+j} \;=\; \sum_{h=0}^{i+j}\binom{i+j}{h}a^h b^{i+j-h}\\
&=\; \sum_{h=0}^{i}\binom{i+j}{h}a^h b^{i+j-h} + \sum_{h=i+1}^{i+j} a^h b^{i+j-h}\\
&=\; b^j\sum_{h=0}^{i}\binom{i+j}{h}a^h b^{i-h} + a^i\sum_{h=1}^{j}\binom{i+j}{i+h}a^h b^{j-h}\\
&\in\; \mathfrak{b}^j + \mathfrak{a}^i
\end{aligned}$$

(iii) We will use induction on k. The case $k=1$ is trivial and hence we found the induction at $k=2$. In this case let us first choose $a_1, a_2\in\mathfrak{a}$, $b_1\in\mathfrak{b}_1$ and $b_2\in\mathfrak{b}_2$ such that $a_1+b_1 = 1$ and $a_2+b_2 = 1$. Then

$$b_1b_2 \;=\; (1-a_1)(1-a_2) \;=\; 1-a_1-a_2+a_1a_2$$

This implies $1 = (a_1+a_2-a_1a_2)+b_1b_2 \in \mathfrak{a}+\mathfrak{b}_1\mathfrak{b}_2$ which rests the case $k=2$. So we now assume $k\geq 2$ and are given $\mathfrak{a}+\mathfrak{b}_i = R$ for any $i\in 1\ldots k+1$. By induction hypothesis we in particular get $\mathfrak{a}+\mathfrak{b}_1\ldots\mathfrak{b}_k = R$. And together with $\mathfrak{a}+\mathfrak{b}_{k+1} = R$ and the case $k=2$ this yields the induction step $\mathfrak{a}+(\mathfrak{b}_1\ldots\mathfrak{b}_k)\mathfrak{b}_{k+1} = R$.

(iv) We will prove the two inclusions by induction on k separately. The case $k=1$ is trivial, so we will start with $k=2$ only. In this case the inclusion $\mathfrak{a}_1\mathfrak{a}_2 \subseteq \mathfrak{a}_1\cap\mathfrak{a}_2$ has already been proved. And if $k\geq 2$ then

$$(\mathfrak{a}_1\ldots\mathfrak{a}_k)\mathfrak{a}_{k+1} \;\subseteq\; (\mathfrak{a}_1\ldots\mathfrak{a}_k)\cap\mathfrak{a}_{k+1} \;\subseteq\; (\mathfrak{a}_1\cap\cdots\cap\mathfrak{a}_k)\cap\mathfrak{a}_{k+1}$$

due to the case $k=2$ and the induction hypothesis respectively. For the converse inclusion we start with $k=2$ again. And as $\mathfrak{a}_1$ and $\mathfrak{a}_2$ are coprime we may find $a_1\in\mathfrak{a}_1$ and $a_2\in\mathfrak{a}_2$ such that $a_1+a_2 = 1$. If now $x\in\mathfrak{a}_1\cap\mathfrak{a}_2$ is an arbitrary element then

$$x \;=\; x1 \;=\; x(a_1+a_2) \;=\; xa_1+xa_2 \;=\; a_1x+a_2x \;\in\; \mathfrak{a}_1\mathfrak{a}_2$$

This proves $\mathfrak{a}_1 \cap \mathfrak{a}_2 \subseteq \mathfrak{a}_1\mathfrak{a}_2$ and hence we may commence with $k \geq 2$. In this case we are given some $x \in \mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_k \cap \mathfrak{a}_{k+1}$. In particular this is $x \in \mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_k$ and hence $x \in \mathfrak{a}_1 \ldots \mathfrak{a}_k$ by induction hypothesis. Thus we get $x \in (\mathfrak{a}_1 \ldots \mathfrak{a}_k) \cap \mathfrak{a}_{k+1}$. But because of (iii) (using $\mathfrak{a} := \mathfrak{a}_{k+1}$ and $\mathfrak{b}_i := \mathfrak{a}_i$) we know that $\mathfrak{a}_1 \ldots \mathfrak{a}_k$ and $\mathfrak{a}_{k+1}$ are coprime. Therefore we may apply the case $k = 2$ again to finally find $x \in (\mathfrak{a}_1 \ldots \mathfrak{a}_k)\mathfrak{a}_{k+1}$.

□

Proof of (1.62):
We first prove that $\sim$ is an equivalence relation: *Reflexivity* $a \sim a$ is clear, as $a - a = 0 \in \mathfrak{a}$. *Symmetry* if $a \sim b$ then $a - b \in \mathfrak{a}$ and hence $b - a = -(a - b) \in \mathfrak{a}$ which proves $b \sim a$. *Transitivity* if $a \sim b$ and $b \sim c$ then $a - c = (a - b) + (b - c) \in \mathfrak{a}$ such that $a \sim c$. If now $a \in R$ then

$$\begin{aligned} [a] &= \{\, b \in R \mid a \sim b \,\} = \{\, b \in R \mid a - b \in \mathfrak{a} \,\} \\ &= \{\, b \in R \mid \exists h \in \mathfrak{a} : a - b = h \,\} \\ &= \{\, a + h \mid h \in \mathfrak{a} \,\} = a + \mathfrak{a} \end{aligned}$$

Now assume that $\mathfrak{a} \trianglelefteq_{\mathrm{i}} R$ even is an ideal, then we have to prove, that $R/\mathfrak{a}$ is a ring under the operations $+$ and $\cdot$ as we have introduced them. Thus we prove the well-definedness: suppose $a + \mathfrak{a} = a' + \mathfrak{a}$ and $b + \mathfrak{a} = b' + \mathfrak{a}$ then $a - a'$ and $b - b' \in \mathfrak{a}$ and hence $(a + b) - (a' + b') = (a - a') + (b - b') \in \mathfrak{a}$. This means $a + b \sim a' + b'$ and hence $(a + b) + \mathfrak{a} = (a' + b') + \mathfrak{a}$. Analogously

$$ab - a'b' = ab - a'b + a'b - a'b' = (a - a')b + a'(b - b')$$

As $\mathfrak{a}$ is an ideal both $(a - a')b$ and $a'(b - b')$ are contained in $\mathfrak{a}$ and hence also the sum $ab - a'b' \in \mathfrak{a}$. This means $ab \sim a'b'$ and hence $ab + \mathfrak{a} = a'b' + \mathfrak{a}$. Hence these operations are well-defined. And all the properties (associativity, commutativity, distributivity and so forth) are immediate from the respective properties of R. This also shows that $1 + \mathfrak{a}$ is the unit element of $R/\mathfrak{a}$ (supposed 1 is the unit element of R). □

Proof of (1.64):
First of all we have (a) $\implies$ (c) because $b \in b + n\mathbb{Z} = a + n\mathbb{Z}$ gives some $c \in n\mathbb{Z}$ such that $b = a + c$. And $c \in n\mathbb{Z}$ means nothing but $c = kn$ for some $k \in \mathbb{Z}$. For (c) $\implies$ (b) we use division with remainder (1.28) to write $a = pn + r$ and $b = qn + s$ such that $r = a \mod n$ and $s = b \mod n$. Then we can compute

$$qn + s = b = a + kn = pn + r + kn = (p + k)n + r$$

which yields $s - r = (p + k - q)n$ such that $|s - r| = |p + k - q| \cdot n$. As r and s both are positive, this implies that $0 \leq |s - r| < \max\{\, s, r \,\} < n$. But this can only be, if $|p + k - q| = 0$ such that $q = n + k$ and $r = s$. And the latter just is the claim (b). It remains to prove (b) $\implies$ (a): continueing with the notation we have $r = s$ and hence $b - a = qn + s - qn - r = (q - p)n$. Letting $k := q - p$ we have $b - a = kn \in n\mathbb{Z}$. That is a and b are equivalent and hence have the same equivalence classes $a + n\mathbb{Z} = b + n\mathbb{Z}$. □

Proof of (1.66):

- We first prove that $\mathfrak{b}/\mathfrak{a}$ truly is an ideal of $R/\mathfrak{a}$. Thus regard $a + \mathfrak{a}$ and $b + \mathfrak{a} \in \mathfrak{b}/\mathfrak{a}$, that is a,

$b \in \mathfrak{b}$. Then we clearly get $a+b$ and $-a \in \mathfrak{b}$ such that $(a+\mathfrak{a})+(b+\mathfrak{a}) = (a+b)+\mathfrak{a} \in \mathfrak{b}/\mathfrak{a}$ and $-(a+\mathfrak{a}) = (-a)+\mathfrak{a} \in \mathfrak{b}/\mathfrak{a}$. Further if $f+\mathfrak{a} \in R/\mathfrak{a}$ (that is $f \in R$) then fb, $bf \in \mathfrak{b}$, as $\mathfrak{b}$ is an ideal. And hence $(f+\mathfrak{a})(b+\mathfrak{a}) = (fb)+\mathfrak{a} \in \mathfrak{b}/\mathfrak{a}$, likewise $(b+\mathfrak{a})(f+\mathfrak{a}) \in \mathfrak{b}/\mathfrak{a}$.

- Next we prove that $\mathfrak{b} := \{b \in R \mid b+\mathfrak{a} \in \mathfrak{u}\} \trianglelefteq_{\mathfrak{i}} R$ is an ideal, supposed $\mathfrak{u} \trianglelefteq_{\mathfrak{i}} R/\mathfrak{a}$ is an ideal. Thus consider a, $b \in \mathfrak{b}$ then $(a+b)+\mathfrak{a} = (a+\mathfrak{a})+(b+\mathfrak{a}) \in \mathfrak{u}$ and $(-a)+\mathfrak{a} = -(a+\mathfrak{a}) \in \mathfrak{u}$ which proves $a+b$ and $-a \in \mathfrak{b}$. And if $f \in R$ then $(fb)+\mathfrak{a} = (f+\mathfrak{a})(b+\mathfrak{a}) \in \mathfrak{u}$ which proves $fb \in \mathfrak{b}$ (likewise $bf \in \mathfrak{b}$. Hence $\mathfrak{b}$ is an ideal, and $\mathfrak{a} \subseteq \mathfrak{b}$ is clear, as for any $a \in \mathfrak{a}$ we get $a+\mathfrak{a} = 0+\mathfrak{a} \in \mathfrak{u}$.

- Thus we have proved that the maps $\mathfrak{b} \mapsto \mathfrak{b}/\mathfrak{a}$ and $\mathfrak{u} \mapsto \mathfrak{b}$ are well defined. We now claim that they even are mutually inverse. For the first composition we start with $\mathfrak{a} \subseteq \mathfrak{b} \trianglelefteq_{\mathfrak{i}} R$. Then

$$\mathfrak{b} \;\mapsto\; \mathfrak{b}\Big/_{\mathfrak{a}} \;\mapsto\; \left\{ b \in R \mid b+\mathfrak{a} \in \mathfrak{b}\Big/_{\mathfrak{a}} \right\} \;=\; \{\, b \mid b \in \mathfrak{b} \,\} \;=\; \mathfrak{b}$$

 For the converse composition we start with an ideal $\mathfrak{u} \trianglelefteq_{\mathfrak{i}} R/\mathfrak{a}$, which is mapped to $\mathfrak{b} := \{b \in R \mid b+\mathfrak{a} \in \mathfrak{u}\}$. Now it is easy to see that

$$\mathfrak{u} \;\mapsto\; \mathfrak{b} \;\mapsto\; \mathfrak{b}\Big/_{\mathfrak{a}} \;=\; \{\, b+\mathfrak{a} \mid b+\mathfrak{a} \in \mathfrak{u} \,\} \;=\; \mathfrak{u}$$

(i) By now we have established the correspondence of ideals. In the next step we need to prove, that this correspondence is compatible with the generation of ideals: For the inclusion " $\supseteq$ " we begin with any $u \in \langle X/\mathfrak{a}\rangle_{\mathfrak{i}}$. That is there are $a_i+\mathfrak{a}$, $b_i+\mathfrak{a} \in R/\mathfrak{a}$ and $x_i+\mathfrak{a} \in X/\mathfrak{a}$ such that

$$\begin{aligned} u &= \sum_{i=1}^{k} (a_i+\mathfrak{a})(x_i+\mathfrak{a})(b_i+\mathfrak{a}) \\ &= \left(\sum_{i=1}^{k} a_i x_i b_i\right) + \mathfrak{a} \;\in\; \langle X\rangle_{\mathfrak{i}} + \mathfrak{a}\Big/_{\mathfrak{a}} \end{aligned}$$

 And for the converse inclusion " $\subseteq$ " we are given some $a \in \mathfrak{a}$ and $y \in \langle X\rangle_{\mathfrak{i}}$. The element y generated by X is of the follwing form: There are some a_i, $b_i \in R$ and $x_i \in X$ such that $y = \sum_i a_i x_i b_i$. Using this we undo the above computation to find

$$(a+y)+\mathfrak{a} \;=\; y+\mathfrak{a} \;=\; \sum_{i=1}^{k} (a_i+\mathfrak{a})(x_i+\mathfrak{a})(b_i+\mathfrak{a}) \;\in\; \langle X\Big/_{\mathfrak{a}}\rangle_{\mathfrak{i}}$$

(ii) The identity of the sums is a no-brainer: The elements of the sum of the ideals $\mathfrak{b}_i$ are finite sums $b_1+\cdots+b_n$ where $b_k \in \mathfrak{b}_{i(k)}$ for some $i(k) \in I$. But then we immediately find

$$\left(\sum_{k=1}^{n} b_k\right) + \mathfrak{a} \;=\; \sum_{k=1}^{n} (b_k+\mathfrak{a}) \;\in\; \sum_{k=1}^{n} \mathfrak{b}_{i(k)}\Big/_{\mathfrak{a}} \;\subseteq\; \sum_{i\in I} \mathfrak{b}_i\Big/_{\mathfrak{a}}$$

 Conversely the elements of the sum of quotient ideals $\mathfrak{b}_i/\mathfrak{a}$ are finite sums of the following form,

where $b_k \in \mathfrak{b}_{i(k)}$ for some $i(k) \in I$ again. Thus the same computation reversed yields

$$\sum_{k=1}^{n} (b_k + \mathfrak{a}) \;=\; \left(\sum_{k=1}^{n} b_k \right) + \mathfrak{a} \;\in\; \textstyle\sum_{k=1}^{n} \mathfrak{b}_{i(k)} \Big/ \mathfrak{a} \;\subseteq\; \sum_{i \in I} \mathfrak{b}_i \Big/ \mathfrak{a}$$

(ii) Now to the identity of the intersections, the inclusion " $\supseteq$ " is elementary logic: If we regard any $x + \mathfrak{a}$, where x is contained in the intersection of the $\mathfrak{b}_i$ then $x \in \mathfrak{b}_i$ for any $i \in I$. Hence $x + \mathfrak{a} \in \mathfrak{b}_i/\mathfrak{a}$ is granted. And as this is true for any $i \in I$ we find $x + \mathfrak{a}$ in the intersection of the $\mathfrak{b}_i/\mathfrak{a}$. The converse inclusion "$\subseteq$" makes use of the ideals: Consider any $x + \mathfrak{a}$ in the intersection of the $\mathfrak{b}_i/\mathfrak{a}$. That is for any $i \in I$ there is some $b_i \in \mathfrak{b}_i$ such that $x + \mathfrak{a} = b_i + \mathfrak{a}$. But we need the same b for all $i \in I$. So fix any $j \in I$, let $b := b_j$ and consider any $i \in I$. As $b + \mathfrak{b}_j = x + \mathfrak{a} = b_i + \mathfrak{a}$ we get $a_i := b - b_i \in \mathfrak{a}$. But we clearly have $b = b_i + a_i$ and $b_i \in \mathfrak{b}_i$ and $a_i \in \mathfrak{a} \subseteq \mathfrak{b}_i$ by construction. Thus we see, that $b \in \mathfrak{b}_i$ and as $i \in I$ was arbitrary, this means $b \in \bigcap_i \mathfrak{b}_i$. And from this we get

$$x + \mathfrak{a} \;=\; b + \mathfrak{a} \;\in\; \bigcap_{i \in I} \mathfrak{b}_i \Big/ \mathfrak{a}$$

(iii) Now for the identity of the product of finitely many ideals: Let us use induction on the number $n := \#I$ of ideals involved. For $n = 1$ the statement is trivial. For the induction step we may regard $\mathfrak{b} := \mathfrak{b}_1 \ldots \mathfrak{b}_n$ and $\mathfrak{c} := \mathfrak{b}_{n+1}$ as the multiplication of ideals is associative. So it suffices to regard the case $n = 2$, that is two ideals $\mathfrak{b}$ and $\mathfrak{c} \trianglelefteq_{\mathrm{i}} R$ with $\mathfrak{a} \subseteq \mathfrak{b}$ and $\mathfrak{a} \subseteq \mathfrak{c}$. For these we find the identity

$$\begin{aligned} \mathfrak{b} \Big/ \mathfrak{c} \,\Big/ \mathfrak{c} \;&=\; \left\{ \sum_{i=1}^{n} (b_i + \mathfrak{a})(c_i + \mathfrak{a}) \;\middle|\; b_i \in \mathfrak{b}, c_i \in \mathfrak{c} \right\} \\ &=\; \left\{ \left(\sum_{i=1}^{n} b_i c_i \right) + \mathfrak{a} \;\middle|\; b_i \in \mathfrak{b}, c_i \in \mathfrak{c} \right\} \;=\; \mathfrak{b}\,\mathfrak{c} \Big/ \mathfrak{c} \end{aligned}$$

- We now prove that this correspondence even interlocks radical ideals. First note that $\mathfrak{b} \trianglelefteq_{\mathrm{i}} R$ is radical iff $\sqrt{\mathfrak{b}} = \mathfrak{b}$. Now remark that $(b + \mathfrak{a})^k = b^k + \mathfrak{a} \in \mathfrak{b}/\mathfrak{a}$ is (by definition) equivalent to $b^k \in \mathfrak{b}$. Thus we found

 $$\sqrt{\mathfrak{b} \Big/ \mathfrak{a}} \;=\; \sqrt{\mathfrak{b}} \Big/ \mathfrak{a}$$

 And in particular we see that $\mathfrak{b}/\mathfrak{a}$ is a redical ideal if and only if $\mathfrak{b}$ is a radical ideal. And this has been claimed.
